on its surface gradually thickens, and a number of white round bodies appear on different parts of it. These bodies also are phosphat of lime, prevented from crystallizing regularly by the too rapid abstraction of moisture. Mr Vauquelin found that 100 parts of semen contain three parts of phosphat of lime.† If at this period of the evaporation the air becomes moist, other crystals appear in the semen, which have the properties of carbonat of soda. The evaporation does not go on to complete exsiccation, unless at the temperature of 77°, and when the air is very dry. When all the moisture is evaporated, the semen has lost 0.9 of its weight, the residuum is semi-transparent like horn, and brittle.‡

u- , Ann. im. p. … d.

When semen is kept in very moist air, at the temperature of about 77°, it acquires a yellow colour, like that of the yolk of an egg; its taste becomes acid, it exhales the odour of putrid fish, and its surface is covered with abundance of the byssus septica.§

When dried semen is exposed to heat in a crucible, it melts, acquires a brown colour, and exhales a yellow fume, having the odour of burnt horn. When the heat is raised, the matter swells, becomes black, and gives out a strong odour of ammonia. When the odour of ammonia disappears, if the matter be lixiviated with water, an alkaline solution may be obtained, which, by evaporation, yields crystals of carbonat of soda. Mr Vauquelin found that 100 parts of semen contain one part of soda.¶ If the residuum be incinerated, there will remain only a quantity of white ashes, consisting of phosphat of lime.

d. p.

Thus it appears that semen is composed of the following ingredients:

90 water,
6 mucilage,
3 phosphat of lime,
1 soda,
———
100

Sect. XV. *Liquor of the Amnios.*

The fœtus in the uterus is enveloped in a peculiar membranous covering, to which anatomists have given the name of *amnios*. Within this amnios there is a liquid, distinguished by the name of the *liquor of the amnios*, which surrounds the fœtus on every part. This liquid, as might have been expected, is very different in different animals, at least the liquor amnii in women and in cows, which alone have hitherto been analysed, have not the smallest resemblance to each other. These two liquids have been lately analysed by Vauquelin and Buniva, and the result of their analysis has been published in the 33d volume of the *Annales de Chimie*.

03 or of uman os.

1. The liquor of the amnios of women is a fluid of a slightly milky colour, a weak but pleasant odour, and a saltish taste. The white colour is owing to a curdy matter suspended in it, for it may be obtained quite transparent by filtration.*

n. de xxxiii.

Its specific gravity is 1.005. It gives a green colour to the tincture of violets, and yet it reddens very decidedly the tincture of turnsol. These two properties would indicate at once the presence of an acid and of an alkali. It froths considerably when agitated. On the application of heat it becomes opaque, and has then a great resemblance to milk diluted with a large quantity of water. At the same time it exhales the odour of boiled white of egg.†

Liquor of the Amnios.

Acids render it more transparent. Alkalies precipitate an animal matter in small flakes. Alcohol likewise produces a flaky precipitate, which, when collected and dried, becomes transparent, and very like glue. The infusion of nut-galls produces a very copious brown coloured precipitate. Nitrat of silver occasions a white precipitate, which is insoluble in nitric acid, and consequently is muriat of silver.†

† Ann. de Chim. xxxiii. 271.

† Ibid.

When slowly evaporated it becomes slightly milky, a transparent pellicle forms on its surface, and it leaves a residuum which does not exceed 0.012 of the whole. By lixiviating this residuum, and evaporating the ley, crystals of muriat and carbonat of soda, may be obtained. The remainder, when incinerated, exhales a fetid and ammoniacal odour, resembling that of burning horn; the ashes consist of a small quantity of carbonat of soda, and of phosphat and carbonat of lime.‡

‡ Ibid, p. 272.

Thus we see that the liquor of the human amnios is composed of about

98.8 water,
1.2 { albumen, muriat of soda, soda, phosphat of lime, lime,
———
100.0

304 Curdy matter deposited on the fœtus.

While the fœtus is in the uterus, a curdy-like matter is deposited on the surface of its skin, and in particular parts of its body. This matter is often found collected in considerable quantities. It is evidently deposited from the liquor of the amnios; and consequently the knowledge of its peculiar nature must throw considerable light upon the properties and use of that liquor. For an analysis of this substance we are also indebted to Vauquelin and Buniva.

Its colour is white and brilliant: it has a soft feel, and very much resembles newly prepared soap. It is insoluble in water, alcohol, and oils. Pure alkalies dissolve part of it, and form with it a kind of soap. On burning coals it decrepitates like a salt, becomes dry and black, exhales vapours which have the odour of empyreumatic oil, and leaves a residuum which is very difficultly reduced to ashes. When heated in a platinum crucible it decrepitates, lets an oil exsude, curls up like horn, and leaves a residuum, consisting chiefly of carbonat of lime.‡

‡ Ibid, p. 274.

These properties shew that this matter is different from every one of the component parts of the liquor of the amnios, and that it has a great resemblance to the *fat*. It is probable, as Vauquelin and Buniva have conjectured, that it is formed from the albumen of that liquid, which has undergone some unknown changes. It has been long known, that the parts of a fœtus which has lain for some time after it has been deprived of life in the uterus, are sometimes converted into a kind of fatty matter. It is evident that this substance, after it is deposited upon the skin of the fœtus, must preserve it in a great measure from being acted upon by the liquor of the amnios.

305 Liquor of the amnios of the cow.

2. The liquor of the amnios of the cow has a viscidity similar to mucilage of gum arabic, a brownish red colour, an acid and bitter taste, and a peculiar odour, not unlike that of some vegetable extracts. Its specific gravity is 1.028. It reddens the tincture of turnsol,

and

Liquor of the Amnios. and therefore contains an acid. Muriat of barytes causes a very abundant precipitate, which renders it probable that it contains sulphuric acid. Alcohol separates from it a great quantity of a reddish coloured matter.§

§ Ann. de Chim. xxxiii. p. 275.

306 Its component parts. When this liquid is evaporated, a thick frothy scum gathers on the surface, which is easily separated, and in which some white acid-tasted crystals may be discovered. By continuing the evaporation, the matter becomes thick, and viscid, and has very much the look of honey. Alcohol boiled upon this thick matter, and filtered off, deposites upon cooling brilliant needle-formed crystals nearly an inch in length. These crystals may be obtained in abundance by evaporating the liquor of the amnios to a fourth part of its bulk, and then allowing it to cool. The crystals soon make their appearance. They may be separated and purified by washing them in a small quantity of cold water. These crystals have the properties of an acid.§

§ Ibid, p. 276.

If after the separation of this acid the liquor of the amnios be evaporated to the consistence of a syrup, large transparent crystals appear in it, which have all the properties of sulphat of soda. The liquid of the amnios of cows contains a considerable quantity of this salt.

Thus it appears that the liquor of the amnios of cows contains the following ingredients:

1. Water,
2. A peculiar animal matter,
3. A peculiar acid,
4. Sulphat of soda.

307 Nature of the animal matter. The animal matter possesses the following properties: It has a reddish brown colour, and a peculiar taste; it is very soluble in water, but insoluble in alcohol, which has the property of separating it from water. When exposed to a strong heat it swells, exhales first the odour of burning gum, then of empyreumatic oil and of ammonia, and at last the peculiar odour of prussic acid becomes very conspicuous. It differs from gelatine in the viscidity which it communicates to water, in not forming a jelly when concentrated, and in not being precipitated by tan. It must be therefore ranked among the very undefined and inaccurate class of *animal mucilages*.

When burnt, it leaves a very large coal, which is readily incinerated, and leaves a little white ashes, composed of phosphat of magnesia, and a very small proportion of phosphat of lime.‖

‖ Ibid, p. 278.

308 Amniotic acid. The acid substance is of a white and brilliant colour; its taste has a very slight degree of sourness; it reddens the tincture of turnsol; it is scarcely soluble in cold water, but very readily in hot water, from which it separates in long needles as the solution cools. It is soluble also in alcohol, especially when assisted by heat. It combines readily with pure alkalies, and forms a substance which is very soluble in water. The other acids decompose this compound; and the acid of the liquor of the amnios is precipitated in a white crystalline powder. This acid does not decompose the alkaline carbonats at the temperature of the atmosphere, but it does so when assisted by heat. It does not alter solutions of silver, lead, or mercury, in nitric acid. When exposed to a strong heat, it frothes and exhales an odour of ammonia and of prussic acid. The properties are sufficient to shew that it is different from every other acid. Vauquelin and Boniva have given it the name of *amniotic acid*. It approaches nearest to the saccholactic and the *uric* acids; but the sachlactic acid does not furnish ammonia by distillation like the amniotic. The uric acid is not so soluble in hot water as the amniotic, it does not crystallize in white brilliant needles, and it is insoluble in boiling alcohol; in both which respects it differs completely from amniotic acid.*

* Ann. de Chim. xxxiii. p. 279.

Sect. XVI. *Of Urine.*

309 Urine. No animal substance has attracted more attention than urine, both on account of its supposed connection with various diseases, and on account of the very singular products which have been obtained from it. Mr Boyle, and the other chemists who were his contemporaries, were induced to attend particularly to this liquid, by the discovery of a method of obtaining phosphorus from it. Boerhaave, Haller, Haupt, Margraf, Pott, Rouelle, Proust, and Klaproth, successively improved the method of obtaining the phosphoric salts from urine, or added something to our knowledge of the component parts of these salts. Scheele added greatly to our knowledge of urine by detecting several new substances in it which had not been suspected. Cruickshank has given us a very valuable paper on urine in the second edition of *Rollo's Diabetes*; and Fourcroy and Vauquelin have lately published the most complete analysis of it which has hitherto appeared.

Fresh urine is a liquid of a peculiar aromatic odour, an orange colour, of greater or less intensity, and an acrid saline taste.

Its specific gravity varies from 1.005 to 1.033.*

* Cruickshank, Phil. Mag. ii. 240.

1. It reddens paper stained with turnsol and with the juice of radishes, and therefore contains an acid.

310 Contains phosphat of lime. 2. If a solution of ammonia be poured into fresh urine, a white powder precipitates, which has the properties of phosphat of lime. The presence of this substance in urine was first discovered by Scheele.† If lime water be poured into urine, phosphat of lime precipitates in greater abundance than when ammonia is used; consequently the acid which urine contains is the phosphoric. Thus we see that the phosphat of lime is kept dissolved in urine by an excess of acid. This also was first discovered by Scheele.‡ This substance is most abundant in the urine of the sick. Berthollet has observed, that the urine of gouty people is less acid than that of people in perfect health. The average quantity of phosphat of lime in healthy urine is, as Cruickshank has ascertained, about $\frac{1}{500}$ of the weight of the urine.§

† Scheele, 208.

‡ Ibid.

§ Phil. Mag. ii. 241.

311 Phosphat of magnesia. 3. If the phosphat of lime precipitated from urine be examined, a little magnesia will be found mixed with it. Fourcroy and Vauquelin have ascertained that this is owing to a little phosphat of magnesia which urine contains, and which is decomposed by the alkali or lime employed to precipitate the phosphat of lime.¶

¶ Ann. de Chim. xxxi. 66.

312 Uric acid. 4. When fresh urine cools, it often lets fall a brick coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid, even when no sensible precipitate appears when it cools. For if a sufficient quantity of clear and fresh urine be evaporated to $\frac{1}{12}$ of its weight, a subtle powder precipitates to the bottom, and attaches itself in part very firmly to the vessel. This part may be dissolved in pure alkali, and precipitated again by acetous acid. It exhibits all the properties of uric acid.* The quantity of uric acid in urine is very various. During intermittent

* Scheele, 207.

termittent ſevers it is depoſited very copiouſly, and has been long known to phyſicians under the name of *lateritious ſediment*. This ſediment always makes its appearance at the criſis of fevers. In gouty people, the ſame ſediment appears in equal abundance towards the end of a paroxyſm of the diſeaſe(P). And if this ſediment ſuddenly diſappears after it has begun to be depoſited, a freſh attack may be expected.*

5. If freſh urine be evaporated to the conſiſtence of a ſyrup, and muriatic acid be then poured into it, a precipitate appears which poſſeſſes the properties of benzoic acid. Scheele firſt diſcovered the preſence of benzoic acid in urine. He evaporated it to dryneſs, ſeparated the ſaline part, and applied heat to the reſiduum. The benzoic acid was ſublimed, and found cryſtallized in the receiver. The method which we have given is much eaſier; it was firſt propoſed by Fourcroy and Vauquelin.† By it very conſiderable quantities of benzoic acid may be obtained from the urine of horſes and cows, where it is much more abundant than in human urine. In human urine it varies from $\frac{1}{1000}$ to $\frac{1}{10000}$ of the whole.§

6. When an infuſion of tan is dropt into urine, a white precipitate appears, having the properties of the combination of tan and albumen, or gelatine. Urine, therefore, contains albumen and gelatine. Theſe ſubſtances had been ſuſpected to be in urine, but their preſence was firſt demonſtrated by Seguin, who diſcovered the above method of detecting them. Their quantity in healthy urine is very ſmall. Cruickſhank found that the precipitate afforded by tan in healthy urine amounted to $\frac{1}{240}$th part of the weight of the urine.‡ It is to theſe ſubſtances that the appearance of the *cloud*, as it is called, or the mucilaginous matter, which is ſometimes depoſited as the urine cools, is owing. It is probable that healthy urine contains only gelatine and not albumen, though the quantity is too ſmall to admit of accurate examination; but in many diſeaſes the quantity of theſe matters is very much increaſed. The urine of dropſical people often contains ſo much albumen, that it coagulates not only on the addition of acids, but even on the application of heat.§ In all caſes of impaired digeſtion, the albuminous and gelatinous part of urine is much increaſed. This forms one of the moſt conſpicuous and important diſtinctions between the urine of thoſe who enjoy good and bad health.‖

7. If urine be evaporated by a ſlow fire to the conſiſtence of a thick ſyrup, it aſſumes a deep brown colour, and exhales a fetid ammoniacal odour. When allowed to cool, it concretes into a maſs of cryſtals, compoſed of all the component parts of urine. If four times its weight of alcohol be poured upon this maſs, at intervals, and a ſlight heat be applied, the greateſt part of it is diſſolved. The alcohol, which has acquired a brown colour, is to be decanted off, and diſtilled in a crucible in a ſand heat, till the mixture has boiled for ſome time, and acquired the conſiſtence of a ſyrup. By this time the whole of the alcohol has paſſed off, and the matter, on cooling, cryſtallizes in quadrangular plates which interſect each other. This ſubſtance is *urea*, which compoſes $\frac{19}{20}$ of the urine, provided the watery part be excluded. To this ſubſtance the taſte, ſmell, and colour of urine are owing. It is a ſubſtance which characterizes urine, and conſtitutes it what it is, and to which the greater part of the very ſingular phenomena of urine are to be aſcribed.

Urine.

The colour of urine depends upon the urea; the greater the quantity, the deeper is the colour. It may be detected by evaporating urine to the conſiſtence of a ſyrup, and pouring into it concentrated nitric acid. Immediately a great number of white ſhining cryſtals appear in the form of plates, very much reſembling cryſtallized boracic acid. Theſe cryſtals are urea combined with nitric acid.

The quantity of urea varies exceedingly in different urines. In the urine voided ſoon after a meal, very little of it is to be found, and ſcarcely any at all in that which hyſterical patients void during a paroxyſm.

316 Muriat of ſoda,

8. If urine be ſlowly evaporated to the conſiſtence of a ſyrup, a number of cryſtals make their appearance in it. Two of theſe are remarkable by their form: one of them conſiſts of ſmall regular octahedrons; which, when examined, are found to poſſeſs the properties of muriat of ſoda. Urine, therefore, contains muriat of ſoda. It is well known that muriat of ſoda cryſtallizes in cubes; the ſingular modification of its form in urine is owing to the action of urea. It has been long known that urine ſaturated with muriat of ſoda depoſites that ſalt in regular octahedrons.

317 Muriat of ammonia,

9. Another of the ſalts which appear during the evaporation of urine has the form of regular cubes. This ſalt has the properties of muriat of ammonia. Now the uſual form of the cryſtals of muriat of ammonia is the octahedron. The change of its form in urine is produced alſo by urea.

318 Phoſphat of ammonia and of ſoda,

10. The ſaline reſiduum which remains after the ſeparation of urea from cryſtallized urine by means of alcohol, has been long known under the names of fuſible ſalt of urine and microcoſmic ſalt. Various methods of obtaining it have been given by chemiſts from Boerhaave, who firſt publiſhed a proceſs, to Rouelle and Chaulnes, who gave the method juſt mentioned. If this ſaline maſs be diſſolved in a ſufficient quantity of hot water, and allowed to cryſtallize ſpontaneouſly in a cloſe veſſel, two ſets of cryſtals are gradually depoſited. The lowermoſt ſet has the figure of flat rhomboidal priſms; the uppermoſt, on the contrary, has the form of rectangular tables. Theſe two may be eaſily ſeparated by expoſing them for ſome time to a dry atmoſphere. The rectangular tables effloreſce and fall to powder, but the rhomboidal priſms remain unaltered.

When theſe ſalts are examined, they are found to have the properties of phoſphats. The rhomboidal priſms conſiſt of phoſphat of ammonia united to a little phoſphat of ſoda; the rectangular tables, on the contrary,

(P) The concretions which ſometimes make their appearance in gouty joints have been found to conſiſt chiefly of uric acid. This ſingular coincidence deſerves the attention of phyſiologiſts: it cannot fail, ſooner or later, to throw light, not only upon gout, but upon ſome of the animal functions.

Urine. trary, are phoſphat of ſoda united to a ſmall quantity of phoſphat of ammonia. Urine, then, contains phoſphat of ſoda and phoſphat of ammonia.

Thus we have found that urine contains the twelve following ſubſtances:

1. Water,	7. Gelatine and albumen,
2. Phoſphoric acid,	8. Urea,
3. Phoſphat of lime,	9. Muriat of ſoda,
4. Phoſphat of magneſia,	10. Muriat of ammonia,
5. Uric acid,	11. Phoſphat of ſoda,
6. Benzoic acid,	12. Phoſphat of ammonia.

319 Sometimes other ſalts. These are the only ſubſtances which are conſtantly found in healthy urine;* but it contains alſo occaſionally other ſubſtances. Very often muriat of potaſs may be diſtinguiſhed among the cryſtals which form during its evaporation. The preſence of this ſalt may always be detected by dropping cautiouſly ſome tartarous acid into urine. If it contains muriat of potaſs, there will precipitate a little tartar, which may eaſily be recogniſed by its properties.*

* *Fourcroy and Vauquelin, Ann. de Chim.* xxxi. 69.

* *Cruickſhank, Phil. Mag.* ii. 241.

Urine ſometimes alſo contains ſulphat of ſoda, and even ſulphat of lime. The preſence of theſe ſalts may be aſcertained by pouring into urine a ſolution of muriat of barytes, a copious white precipitate appears, conſiſting of the barytes combined with phoſphoric acid, and with ſulphuric acid, if any be preſent. This precipitate muſt be treated with a ſufficient quantity of muriatic acid. The phoſphat of barytes is diſſolved, but the ſulphat of barytes remains unaltered.†

† *Fourcroy, Ann. de Chim.* vii. 183.

320 Putrefaction of urine. No ſubſtance putrefies ſooner, or exhales a more deteſtable odour during its ſpontaneous decompoſition, than urine; but there is a very great difference in this reſpect in different urines. In ſome, putrefaction takes place almoſt inſtantaneouſly as ſoon as it is voided; in others, ſcarcely any change appears for a number of days. Fourcroy and Vauquelin have aſcertained that this difference depends on the quantity of gelatine and albumen which urine contains. When there is very little of theſe ſubſtances preſent, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the ſooner does putrefaction commence. The putrefaction of urine, therefore, is, in ſome degree, the teſt of the health of the perſon who has voided it; for a ſuperabundance of gelatine in urine always indicates ſome defect in the power of digeſtion.*

* *Ann. de Chim.* xxxi. 61.

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have ſeen already the facility with which that ſingular ſubſtance is decompoſed, and that the new products into which it is changed are, ammonia, carbonic acid, and acetous acid. Accordingly, the putrefaction of urine is announced by an ammoniacal ſmell. Mucilaginous flakes are depoſited, conſiſting of part of the gelatinous matter. The phoſphoric acid is ſaturated with ammonia, and the phoſphat of lime, in conſequence, is precipitated. Ammonia combines with the phoſphat of magneſia, forms with it a triple ſalt, which cryſtallizes upon the ſides of the veſſel in the form of white cryſtals, compoſed of ſix ſided priſms, terminated by ſix-ſided pyramids. The uric and benzoic acids are ſaturated with ammonia; the acetous acid, and the carbonic acid, which are the products of the decompoſition of the urea, are alſo ſaturated with ammonia, and notwithſtanding the quantity which exhales, the production of this ſubſtance is ſo abundant, that there is a quantity of unſaturated alkali in the liquid. Putrefied urine, therefore, contains chiefly the following ſubſtances, moſt of which are the products of putrefaction:

Ammonia,
Carbonat of ammonia,
Phoſphat of ammonia,
Phoſphat of magneſia and ammonia,
Urat of ammonia,
Acetite of ammonia,
Benzoat of ammonia,
Muriat of ſoda,
Muriat of ammonia;

Beſides the precipitated gelatine and phoſphat of lime.*

* *Ann. Chim.* 70.

The diſtillation of urine produces almoſt the ſame changes; for the heat of boiling water is ſufficient to decompoſe urea, and to convert it into ammonia, carbonic and acetous acids. Accordingly, when urine is diſtilled, there comes over water, containing ammonia diſſolved in it, and carbonat of ammonia in cryſtals. The acids contained in urine are ſaturated with ammonia, and the gelatine and phoſphat of lime precipitate.†

† *Ibid.*

Such are the properties of the human urine. The urine of other animals has not hitherto been examined with equal care; but it is certain that it differs very conſiderably from that of men. The urine of cows and horſes, and of all ruminating animals, for inſtance, contains carbonat of lime, without any mixture of phoſphat of lime.‡ It contains alſo a much greater proportion of benzoic acid than that of man.

‡ *Vau. ibid.* 4.

Sect. XVII. *Of the Urinary Calculus.*

It is well known that concretions not unfrequently form in the bladder, or the other urinary organs, and occaſion one of the moſt diſmal diſeaſes to which the human ſpecies is liable.

3[…] Urinary calculi. Theſe concretions were diſtinguiſhed by the name of *calculi*, from a ſuppoſition that they are of a ſtony nature. They have long attracted the attention of phyſicians. Chemiſtry had no ſooner made its way into medicine than it began to exerciſe its ingenuity upon the urinary calculus; and various theories were given of their nature and origin. According to Paracelſus, who gave them the ridiculous name of *duelech*, urinary calculi were intermediate between tartar and ſtone, and compoſed of an *animal reſin*. Van Helmont pronounced them anomalous coagulations, the offspring of the ſalts of urine, and of a volatile earthy ſpirit, produced at once, and deſtitute of any viſcid matter.§ Boyle extracted from them, by diſtillation, oil, and a great quantity of volatile ſalt. Boerhaave ſuppoſed them compounds of oil and volatile ſalts. Hales extracted from them a prodigious quantity of air. He gave them the name of *animal tartar*, pointed out ſeveral circumſtances in which they reſemble common tartar, and made many experiments to find a ſolvent of them.* Drs Whytt and Alſton pointed out alkalies as ſolvents of calculi. It was an attempt to diſcover a more perfect ſolvent that induced Dr Black to make thoſe experiments which terminated in the diſcovery of the nature of the alkaline carbonats.

§ *De […]*

* *Veg. Stat.* […] 189.

3[…] Analyſis by Sc[heele]. Such was the ſtate of the chemical analyſis of calculus, when, in 1776, Scheele publiſhed a diſſertation on the ſubject in the *Stockholm Tranſactions*; which was ſucceeded by ſome remarks of Mr Bergmann. Theſe illuſtrious

nary culus. illuſtrious chemiſts completely removed the uncertainty which had hitherto hung over the ſubject, and aſcertained the nature of the calculi which they examined. Since that time conſiderable additional light has been thrown upon the nature of theſe concretions by the labours of Auſtin, Pearſon, and, above all, of Fourcroy and Vauquelin, who have lately analyſed above 300
23 calculi, and aſcertained the preſence of ſeveral new ſub-
r com- ſtances which had not been ſuſpected. The ſubſtances
nt hitherto diſcovered in urinary calculi are the following:

1. Uric acid,
2. Urat of ammonia,
3. Phoſphat of lime (q),
4. Phoſphat of magneſia-and-ammonia,
5. Oxalat of lime,
6. Silica,
7. An animal matter.

24
acid. 1. The greater number of calculi conſiſt of uric acid. All thoſe analyſed by Scheele were compoſed of it entirely. Of 300 calculi analyſed by Dr Pearſon, ſcarcely one was found which did not contain a conſiderable quantity of it, and the greater number manifeſtly were formed chiefly of it. Fourcroy and Vauquelin found it alſo in the greater number of the 300 calculi which they analyſed.

The preſence of this acid may eaſily be aſcertained by the following properties: A ſolution of potaſs or ſoda diſſolves it readily, and it is precipitated by the weakeſt acids. The precipitate is ſoluble in nitric acid, the ſolution is of a pink colour, and tinges the ſkin red.*

rcroy, de xxxii.

2. Urat of ammonia is eaſily detected by its rapid ſolubility in fixed alkaline leys, and the odour of ammonia which is perceived during the ſolution. It is not
25 of am- ſo often preſent in urinary calculi as the laſt mentioned
1. ſubſtance. No calculus has hitherto been found compoſed of it alone, except the very ſmall polygonal calculi, ſeveral of which ſometimes exiſt in the bladder together.

It is moſt uſually in thin layers, alternating with ſome other ſubſtance, very eaſily reduced to powder, and of the colour of ground coffee.†

. 218.

26 phat nc. 3. Phoſphat of lime is white, without luſtre, fiery, friable, ſtains the hands, paper, and cloth. It has very much the appearance of chalk, breaks under the forceps, is inſipid, and inſoluble in water. It is ſoluble in nitric, muriatic, and acetous acids, and is again precipitated by ammonia, fixed alkalies, and oxalic acid.

It is never alone in calculi. It is intimately mixed with a gelatinous matter, which remains under the form of a membrane when the earthy part is diſſolved by very diluted acids.‡

27 phat gne- d-am- 1. 4. Phoſphat of magneſia-and-ammonia occurs in white, ſemitranſparent, lameller layers; ſometimes it is cryſtallized on the ſurface of the calculi in priſms, or what are called *dog-tooth* cryſtals. It has a weak ſweetiſh taſte, it is ſomewhat ſoluble in water, and very ſoluble in acids, though greatly diluted. Fixed alkalies decompoſe it.

It never forms entire calculi. Sometimes it is mixed with phoſphat of lime, and ſometimes layers of it cover uric acid or oxalat of lime. It is mixed with the ſame gelatinous matter as phoſphat of lime.‡

Urinary Calculus.

‡ Fourcroy, Ann. de Chim. xxxii. 219.

5. Oxalat of lime is found in certain calculi, which, from the inequality of their ſurface, have got the name of *moriform* or *mulberry-ſhaped* calculi. It is never alone, but combined with a peculiar animal matter, and forming with it a very hard calculus, of a grey colour, difficult to ſaw aſunder, admitting a poliſh like ivory, exhaling, when ſawed, an odour like that of ſemen. Inſoluble and indecompoſible by alkalies; ſoluble in very diluted nitric acid, but ſlowly, and with difficulty. It may be decompoſed by the carbonats of potaſs and ſoda. When burnt, it leaves behind a quantity of pure lime, which may be eaſily recogniſed by its properties.* 328 Oxalat of lime.

* Ibid. 220.

6. Silica has only been found in two inſtances by Fourcroy and Vauquelin, though they analyſed 300 calculi. No other chemiſt has obſerved it. It muſt therefore be conſidered as a very uncommon ingredient of theſe concretions. In the two inſtances in which it occurred, it was mixed with uric acid and the two phoſphats above mentioned.† 329 Silica.

† Ibid. 221.

7. *Animal matter* appears to compoſe the cement which binds the different particles of the calculus together, and in all probability it is the cauſe which influences its formation. It is different in different calculi. Sometimes it has the appearance of gelatine or albumen, at other times it reſembles urea. It deſerves a more accurate inveſtigation.‡ 330 Animal matters.

‡ Ibid.

No general deſcription of the different calculi has hitherto appeared; but Fourcroy and Vauquelin are at preſent occupied with that ſubject. They propoſe to claſſify them according to their compoſition; to point out their different ſpecies and varieties; to give a method of detecting them by their appearance; to analyſe the animal matter by which they are cemented; and to apply all the preſent chemical knowledge of the ſubject in the inveſtigation of the cauſe, the ſymptoms, and the cure, of that dreadful diſeaſe which the urinary calculi produce. As their labour is already very far advanced, it would be unneceſſary for us to attempt any claſſification of calculi. Indeed every attempt of that kind, by any perſon who has not had an opportunity of analyſing a very great number of calculi, muſt be ſo exceedingly imperfect as ſcarcely to be of any uſe.

We ſhall ſatisfy ourſelves with the following remarks, deduced almoſt entirely from the obſervations which theſe celebrated chemiſts have already publiſhed.

331 Method of diſſolving the calculi.

Many calculi conſiſt entirely, or almoſt entirely, of uric acid. The animal matter, which ſerves as a cement to theſe calculi, appears to be urea. Calculi of this kind may be diſſolved by injecting into the bladder ſolutions of pure potaſs or ſoda, ſo much diluted as not to act upon the bladder itſelf. The gritty ſubſtance, which many perſons threatened with the ſtone diſcharge along with their urine, which has been called *gravel*, conſiſts almoſt conſtantly of uric acid. It may therefore ſerve as an indication that the ſubſequent ſtone, if any ſuch form, is probably compoſed of uric acid.

The two phoſphats, mixed together, ſometimes compoſe calculi. Theſe calculi are very brittle, and generally

(q) Brugnatelli found alſo phoſphat of lime, with exceſs of acid, in calculi. See *Ann. de Chim.* xxxii. 183.

Urinary Calculus.

raily break in pieces during the extraction. Such calculi may be dissolved by injecting into the bladder muriatic acid, so much diluted as scarcely to have any taste of acid.

The phosphats never form the nucleus of a calculus. They have never been found covered with a layer of uric acid, but they often cover that acid. Hence it would seem that the existence of any extraneous matter in the bladder disposes these phosphats to crystallize. When extraneous bodies are accidentally introduced into the bladder, and allowed to lodge there, they are constantly covered with a coat of phosphat of ammonia and magnesia, or of the two phosphats mixed.

As the phosphat of ammonia and magnesia is not an ingredient of fresh urine, but formed during its putrefaction, when it exists in calculi, it would seem to indicate a commencement of putrefaction during the time that the urine lodges in the bladder. But putrefaction does not take place speedily in urine, unless where there is an excess of albumen and gelatine; consequently we have reason to suppose, that these substances are morbidly abundant in the urine of those patients who are afflicted with calculi consisting of the phosphats: hence also we may conclude, that their digestion is imperfect. It will no doubt be objected, that dropsical people are not peculiarly subject to calculi; but their urine is only morbidly albuminous when the disease is beginning to disappear, and then there seems to be a deficiency of urea; at least their urine has not been observed to putrefy with uncommon rapidity. Besides, there seems to be some animal matter present, which serves as a cement to the phosphat in all cases where calculi form.

Urat of ammonia is only found alone in the very small polygenous calculi which exist, several together, in the bladder. In other cases it is mixed with uric acid. It sometimes alternates with uric acid or with the phosphats. It is dissolved by the same substance that acts as a solvent of uric acid.

Oxalat of lime often forms the nucleus of calculi composed of layers of uric acid or of the phosphats. It forms those irregular calculi which are called *moriform*. These calculi are the hardest and the most difficult of solution. A very much diluted nitric acid dissolves them but very slowly. As oxalic acid does not exist in urine, some morbid change must take place in the urine when such calculi are deposited. Brugnatelli's discovery of the instantaneous conversion of uric acid into oxalic acid by oxy muriatic acid, which has been confirmed by the experiments of Fourcroy and Vauquelin, throws considerable light upon the formation of oxalic acid in urine, by shewing us that uric acid is probably the basis of it; but in what manner the change is actually produced, it is not so easy to say.

The calculi found in the bladder of other animals have not been examined with the same care. Some of them, however, have been subjected to an accurate analysis. No uric acid has ever been found in any of them. 332 Calculi of inferior animals.

Fourcroy found a calculus extracted from the kidney of a horse composed of three parts of carbonat of lime, and one part phosphat of lime.* Dr Pearson examined a urinary calculus of a horse; it was composed of phosphat of lime and phosphat of ammonia. Brugnatelli found a calculus extracted from the bladder of a sow, which was exceedingly hard, composed of pure carbonat of lime, inclosing a soft nucleus of a fœtid and urinous odour.† Bartholdi examined another calculus of a pig, the specific gravity of which was 1.9300. It consisted of phosphat of lime.‡ Dr Pearson found a calculus taken from the bladder of a dog composed of phosphat of lime, phosphat of ammonia, and an animal matter. He found the urinary calculus of a rabbit, of the specific gravity 2, composed of carbonat of lime and some animal matter.||

We have now given an account of all those secretions which have been attentively examined by chemists. The remainder have been hitherto neglected; partly owing to the difficulty of procuring them, and partly on account of the multiplicity of other objects which occupied the attention of chemical philosophers (R). It remains for us now to examine by what processes these different secretions are formed, how the constant waste of living bodies is repaired, and how the organs themselves are nourished and preserved. This shall form the subject of the following chapter.

Chap. III. Of the Functions of Animals.

The intention of the two last chapters was to exhibit a view of the different substances which enter into the composition of animals, as far as the present limited state of our knowledge puts it in our power. But were our enquiries concerning animals confined to the mere ingredients of which their bodies are composed, even supposing the analysis as complete as possible, our knowledge of the nature and properties of animals would be imperfect indeed.

How are these substances arranged? How are they produced?

(R) The chief of these secretions are the following:

1. Cerumen, or ear-wax, is at first nearly liquid, and of a whitish colour. It gradually acquires consistence. Its taste is very bitter. Said to be insoluble in alcohol; but soluble in hot water. Does not become rancid by keeping.
2. The humours of the eye.
3. The milky liquor, secreted by the thyroid gland.
4. Mucus of the lungs, intestinal canal, &c.
5. Smegma of the areola of the breasts, glans penis, vagina, subcutaneous glands, &c.
6. Marrow.

nctions Animals. produced? What purpoſes do they ſerve? What are the diſtinguiſhing properties of animals, and the laws by which they are regulated?

333 mals mble etables. Animals reſemble vegetables in the complexneſs of their ſtructure. Like them, they are machines nicely adapted for particular purpoſes, conſtituting one whole, and continually performing an infinite number of the moſt delicate proceſſes. But neither an account of the ſtructure of animals, nor of the properties which diſtinguiſh them from other beings, will be expected here. Theſe have been already treated of ſufficiently in the articles ANATOMY and PHYSIOLOGY *(Encycl.)*, to which we beg leave to refer the reader. We mean only, in the preſent chapter, to take a view of thoſe proceſſes which are concerned in the *production* of animal ſubſtances, which alone properly belong to chemiſtry. The other functions are regulated by laws of a very different nature, which have no reſemblance or analogy to the laws of chemiſtry or mechanics.

334 uire l. 1. Every body knows that animals require food, and that they die ſooner or later if food be withheld from them. There is indeed a very great difference in different animals, with regard to the quantity of food which they require, and the time which they can paſs without it. In general, this difference depends upon the activity of the animal. Thoſe which are moſt active require moſt, and thoſe which move leaſt require leaſt food.

The cauſe of this is alſo well known; the bodies of animals do not remain ſtationary, they are conſtantly waſting; and the waſte is generally proportional to the activity of the animal. It is evident, then, that the body muſt receive, from time to time, new ſupplies, in place of what has been carried off. Hence the uſe of food, which anſwers this purpoſe.

335 ature. 2. We are much better acquainted with the food of animals than of vegetables. It conſiſts of almoſt all the animal and vegetable ſubſtances which have been treated of in the former part of this article; for there are but very few of them which ſome animal or other does not uſe as food. Man uſes as food chiefly the muſcles of animals, the ſeeds of certain graſſes, and a variety of vegetable fruits. Almoſt all the inferior animals have particular ſubſtances on which they feed excluſively. Some of them feed on animals, others on vegetables. Man has a greater range; he can feed on a very great number of ſubſtances. To enumerate theſe ſubſtances would be uſeleſs; as we are not able to point out with accuracy what it is which renders one ſubſtance more nouriſhing than another.

Many ſubſtances do not ſerve as nouriſhment at all; and not a few, inſtead of nouriſhing, deſtroy life. Theſe laſt are called *poiſons*. Some poiſons act chemically, by decompoſing the animal body. The action of others is not ſo well underſtood.

336 verted chyme 3. The food is introduced into the body by the mouth, and almoſt all animals reduce it to a kind of pulpy conſiſtence. In man and many other animals this is done in the mouth by means of teeth, and the ſaliva with which it is there mixed; but many other animals grind their food in a different manner. See PHYSIOLOGY, *(Encycl.)* After the food has been thus ground, it is introduced into the ſtomach, where it is ſubjected to new changes. The ſtomach is a ſtrong ſoft bag, of different forms in different animals: in man it has ſome reſemblance to the bag of a *bag-pipe*. In this organ the food is converted into a ſoft pap, which has no reſemblance to the food when firſt introduced. This pap has been called *chyme*. Functions of Animals.

4. Since chyme poſſeſſes new properties, it is evident that the food has undergone ſome changes in the ſtomach, and that the ingredients of which it was compoſed have entered into new combinations. Now, in what manner have theſe changes been produced?

At firſt they were aſcribed to the mechanical action of the ſtomach. The food, it was ſaid, was ſtill farther triturated in that organ; and being long agitated backwards and forwards in it, was at laſt reduced to a pulp. But this opinion, upon examination, was found not to be true. The experiments of Stevens, Reaumur, and Spallanzani, demonſtrated, that the formation of chyme is not owing to trituration; for on incloſing different kinds of food in metallic tubes and balls full of holes, in ſuch a manner as to ſcreen them from the mechanical action of the ſtomach, they found, that theſe ſubſtances, after having remained a ſufficient time in the ſtomach, were converted into chyme, juſt as if they had not been incloſed in ſuch tubes. Indeed, the opinion was untenable, even independent of theſe deciſive experiments, the moment it was perceived that chyme differed entirely from the food which had been taken; that is to ſay, that if the ſame food were triturated mechanically out of the body, and reduced to pap of preciſely the ſame conſiſtence with chyme, it would not poſſeſs the ſame properties with chyme; for whenever this fact was known, it could not but be evident that the food had undergone changes in its compoſition.

The change of food into chyme, therefore, was aſcribed by many to *fermentation*. This opinion is indeed very ancient, and it has had many zealous ſupporters among the moderns. When the word *fermentation* was applied to the change produced on the food in the ſtomach, the nature of the proceſs called fermentation was altogether unknown. The appearances, indeed, which take place during that proceſs, had been deſcribed, and the progreſs and the reſult of it were known. Chemiſts had even divided fermentations into different claſſes; but no attempt had been made to explain the cauſe of fermentation, or to trace the changes which take place during its continuance. All that could be meant, then, by ſaying that the converſion of food into chyme in the ſtomach was owing to fermentation, was merely, that the unknown cauſe which acted during the converſion of vegetable ſubſtances into wine or acid, or during their putrefaction, acted alſo during the converſion of the food into chyme, and that the reſult in both caſes was preciſely the ſame. Accordingly, the advocates for this opinion attempted to prove, that air was conſtantly generated in the ſtomach, and that an acid was conſtantly produced: for it was the vinous and acetous fermentations which were aſſigned by the greater number of phyſiologiſts as the cauſe of the formation of chyme. Some indeed attempted to prove, that it was produced by the putrefactive fermentation; but their number was inconſiderable, compared with thoſe who adopted the other opinion.

Our ideas reſpecting fermentation are now ſomewhat more preciſe. It ſignifies a ſlow decompoſition, which takes place when certain animal or vegetable ſubſtances are mixed together at a given temperature; and the

 conſequent

consequent production of particular compounds. If therefore the conversion of the food into chyme be owing to fermentation, it is evident that it is totally independent of the stomach any farther than as it supplies temperature; and that the food would be converted into chyme exactly in the same manner, if it were reduced to the same consistence, and placed in the same temperature out of the body. But this is by no means the case; substances are reduced to the state of chyme in a short time in the stomach which would remain unaltered for weeks in the same temperature out of the body. This is the case with bones; which the experiments of Stevens and Spallanzani have shewn to be soon digested in the stomach of the dog. Further if the conversion of food into chyme were owing to fermentation, it ought to go on equally well in the stomach and œsophagus. Now, it was observed long ago by Ray and Boyle, that when voracious fish had swallowed animals too large to be contained in the stomach, that part only which was in the stomach was converted into chyme, while what was in the œsophagus remained entire; and this has been fully confirmed by subsequent observations.

Still farther, if the conversion were owing to fermentation, it ought always to take place equally well, provided the temperature be the same, whether the stomach be in a healthy state or not. But it is well known, that this is not the case. The formation of chyme depends very much on the state of the stomach. When that organ is diseased, digestion is constantly ill performed. In these cases, indeed, fermentation sometimes appears, and produces flatulence, acid eructations, &c. which are the well-known symptoms of indigestion. These facts have been long known; they are totally incompatible with the supposition, that the formation of chyme is owing to fermentation. Accordingly that opinion has been for some time abandoned, by all those at least who have taken the trouble to examine the subject.

337 By the action of the gastric juice.

The formation of chyme, then, is owing to the stomach; and it has been concluded, from the experiments of Stevens, Reaumur, Spallanzani, Scopoli, Brugnatelli, Carminati, &c. that its formation is brought about by the action of a particular liquid secreted by the stomach, and for that reason called *gastric juice*.

That it is owing to the action of a liquid, is evident; because if pieces of food be inclosed in close tubes, they pass through the stomach without any farther alteration than would have taken place at the same temperature out of the body: but if the tubes be perforated with small holes, the food is converted into chyme.

This liquid does not act indiscriminately upon all substances: For if grains of corn be put into a perforated tube, and a granivorous bird be made to swallow it, the corn will remain the usual time in the stomach without alteration; whereas if the husk of the grain be previously taken off, the whole of it will be converted into chyme. It is well known, too, that many substances pass unaltered through the intestines of animals, and consequently are not acted upon by the gastric juice. This is the case frequently with grains of oats when they have been swallowed by horses entire with their husks on. This is the case also with the seeds of apples, &c. when swallowed entire by man; yet these very substances, if they have been previously ground sufficiently by the teeth, are digested. It appears, therefore, that it is chiefly the husk or outside of these substances which resists the action of the gastric juice. We see also, that trituration greatly facilitates the conversion of food into chyme.

338 Nature of gastric juice.

The gastric juice is not the same in all animals; for many animals cannot digest the food on which others live. The *conium maculatum* (hemlock), for instance, is a poison to man instead of food, yet the goat often feeds upon it. Many animals, as sheep, live wholly upon vegetables; and if they are made to feed on animals, their stomachs will not digest them: others, again, as the eagle, feed wholly on animal substances, and cannot digest vegetables.

The gastric juice does not continue always of the same nature, even in the same animal: it changes gradually, according to circumstances. Graminivorous animals may be brought to live on animal food; and after they had been accustomed to this for some time, their stomachs become incapable of digesting vegetables. On the other hand, those animals which naturally digest nothing but animal food may be brought to digest vegetables.

What is the nature of the gastric juice, which possesses these singular properties? It is evidently different in different animals; but it is a very difficult task, if not an impossible one, to obtain it in a state of purity. Various attempts have indeed been made by very ingenious philosophers to procure it; but their analysis of it is sufficient to shew us, that they have never obtained it in a state of purity.

The methods which have been used to procure gastric juice are, *first*, to kill the animal whose gastric juice is to be examined after it has fasted for some time. By this method, Spallanzani collected 37 spoonfuls from the two first stomachs of a sheep. It was of a green colour, undoubtedly owing to the grass which the animal had eaten. He found also half a spoonful in the stomach of some young crows which he killed before they had left their nest.

Small tubes of metal, pierced with holes, and containing a dry sponge, have been swallowed by animals; and when vomited up, the liquid imbibed by the sponge is squeezed out. By this method, Spallanzani collected 481 grains of gastric juice from the stomachs of five crows.

A *third* method consists in exciting vomiting in the morning, when the stomach is without food. Spallanzani tried this method twice upon himself, and collected one of the times 1 oz. 32 gr. of liquid; but the pain was so great, that he did not think proper to try the experiment a third time. Mr Gosse, however, who could excite vomiting whenever he thought proper by swallowing air, has employed that method to collect gastric juice.

Spallanzani has observed, that eagles throw up every morning a quantity of liquid, which he considers as gastric juice; and he has availed himself of this to collect it in considerable quantities.

It is almost unnecessary to remark how imperfect these different methods are, and how far every conclusion drawn from the examination of such juices must deviate from the truth. It is impossible that the gastric juice, obtained by any one of these processes, can be pure; because in the stomach it must be constantly mixed ons nals. mixed with large quantities of faliva, mucus, bile, food, &c. It may be queftioned, indeed, whether any gaftric juice at all can be obtained by thefe methods: for as the intention of the gaftric juice is to convert the food into chyme, in all probability it is only fecreted, or at leaft thrown into the ftomach when food is prefent.

We need not be furprifed, then, at the contradictory accounts concerning its nature, given us by thofe philofophers who have attempted to examine it; as thefe relate not fo much to the gaftric juice, as to the different fubftances found in the ftomach. The idea that the gaftric juice can be obtained by vomiting, or that it is thrown up fpontaneoufly by fome animals, is, to fay the leaft of it, very far from being probable.

According to Brugnatelli, the gaftric juice of carnivorous animals, as hawks, kites, &c. has an acid and refinous odour, is very bitter, and not at all watery; and is compofed of an uncombined acid, a refin, an animal fubftance, and a fmall quantity of muriat of foda.* The gaftric juice of herbivorous animals, on the contrary, as goats, fheep, &c. is very watery, a little muddy, has a bitter faltifh tafte, and contains ammonia, an animal extract, and a pretty large quantity of muriat of foda.† Mr Carminati found the fame ingredients; but he fuppofes that the ammonia had been formed by the putrefaction of a part of their food, and that in reality the gaftric juice of thefe animals is of an acid nature.‡

The accounts which have been given of the gaftric juice of man are fo various, that it is not worth while to tranfcribe them. Sometimes it has been found of an acid nature, at other times not. The experiments of Spallanzani are fufficient to fhew, that this acidity is not owing to the gaftric juice, but to the food. He never found any acidity in the gaftric juice of birds of prey, nor of ferpents, frogs, and fifhes. Crows gave an acidulous gaftric juice only when fed on grain; and he found that the fame obfervation holds with refpect to dogs, herbivorous animals, and domeftic fowls. Carnivorous birds threw up pieces of fhells and coral without alteration; but thefe fubftances were fenfibly diminifhed in the ftomachs of hens, even when inclofed in perforated tubes. Spallanzani himfelf fwallowed calcareous fubftances inclofed in tubes; and when he fed on vegetables and fruits, they were fometimes altered and a little diminifhed in weight, juft as if they had been put into weak vinegar; but when he ufed only animal food, they came out untouched. According to this philofopher, whofe experiments have been by far the moft numerous, the gaftric juice is naturally neither acid nor alkaline. When poured on the carbonat of potafs, it caufes no effervefcence.

Such are the refults of the experiments on the juices taken from the ftomach of animals. No conclufion can be drawn from them refpecting the nature of the gaftric juice. But from the experiments which have been made on the digeftion of the ftomach, efpecially by Spallanzani, the following facts are eftablifhed.

The gaftric juice attacks the furfaces of bodies, unites to the particles of them which it carries off, and cannot be feparated from them by filtration. It operates with more energy and rapidity the more the food is divided, and its action is increafed by a warm temperature. The food is not merely reduced to very minute parts; its tafte and fmell are quite changed; its fenfible properties are deftroyed, and it acquires new and very different ones. This juice does not act as a ferment; fo far from it, that it is a powerful antifeptic, and even reftores flefh already putrefied. There is not the fmalleft appearance of fuch a procefs; indeed, when the juice is renewed frequently, as in the ftomach, fubftances diffolve in it with a rapidity which excludes all idea of fermentation. Only a few air bubbles make their efcape, which adhere to the alimentary matter, and buoy it up to the top, and which are probably extricated by the heat of the folution.

Functions of Animals.

With refpect to the fubftances contained in the ftomach, only two facts have been perfectly afcertained: The firft is, that the juice contained in the ftomach of oxen, calves, fheep, invariably contains uncombined phofphoric acid, as Macquart and Vauquelin have demonftrated: The fecond, that the juice contained in the ftomach, and even the inner coat of the ftomach itfelf, has the property of coagulating milk and the ferum of blood. Dr Young found, that feven grains of the inner coat of a calf's ftomach, infufed in water, gave a liquid which coagulated more than 100 ounces of milk; that is to fay, more than 6857 times its own weight; and yet, in all probability, its weight was not much diminifhed.

What the fubftance is which poffeffes this coagulating property, has not yet been afcertained; but it is evidently not very foluble in water: for the infide of a calf's ftomach, after being fteeped in water for fix hours, and then well wafhed with water, ftill furnifhes a liquor on infufion which coagulates milk:* And Dr Young found, that a piece of the inner coat of the ftomach, after being previoufly wafhed with water, and then with a diluted folution of carbonat of potafs, ftill afforded a liquid which coagulated milk and ferum.

It is evident, from thefe facts, that this coagulating fubftance, whatever it is, acts very powerfully; and that it is fcarcely poffible to feparate it completely from the ftomach. But we know at prefent too little of the nature of coagulation to be able to draw any inference from thefe facts. An almoft imperceptible quantity of fome fubftances feems to be fufficient to coagulate milk. For Mr Vaillant mentions in his Travels in Africa, that a porcelain difh which he procured, and which had lain for fome years at the bottom of the fea, poffeffed, in confequence, the property of coagulating milk when put into it; yet it communicated no tafte to the milk, and did not differ in appearance from other cups.

It is probable that the faliva is of fervice in the converfion of food into chyme as well as the gaftric juice. It evidently ferves to dilute the food; and probably it may be ferviceable alfo, by communicating oxygen.

339
Chyme converted into chyle and excrement.

5. The chyme, thus formed, paffes from the ftomach into the inteftines, where it is fubjected to new changes, and at laft converted into two very different fubftances, chyle and excrementitious matter.

6. The *chyle* is a white coloured liquid, very much refembling milk. It is exceedingly difficult to collect it in any confiderable quantity, and for that reafon it has never been accurately analyfed. We know only in general that it refembles milk; containing, like it, an albuminous part capable of being coagulated, a ferum, and globules which have a refemblance to cream.† It contains alfo different falts; and, according to fome, a fubftance fcarcely differing from the fugar of milk. It is probable alfo that it contains iron; but if fo, it muft be

* *Young.*

† *Forfyce on Digeftion*, 121.

be in the ſtate of a white oxyd; for an infuſion of nut galls does not alter the colour of chyle.‡

‡ Fordyce on Digeſtion, 122.

6. Concerning the proceſs by which chyle is formed from chyme, ſcarcely any thing is known. It does not appear that the chyme is preciſely the ſame in all animals; for thoſe which are herbivorous have a greater length of inteſtine than thoſe which are carnivorous. It is certain that the formation of the chyle is brought about by a chemical change, although we cannot ſay preciſely what that change is, or what the agents are by which it is produced. But that the change is chemical, is evident, becauſe the chyle is entirely different, both in its properties and appearance, from the chyme. The chyme, by the action of the inteſtines, is ſeparated into two parts, chyle and excrement: the firſt of which is abſorbed by a number of ſmall veſſels called *lacteals*; the ſecond is puſhed along the inteſtinal canal, and at laſt thrown out of the body altogether.

After the chyme has been converted into chyle and excrement, although theſe two ſubſtances remain mixed together, it does not appear that they are able to decompoſe each other; for perſons have been known ſeldom or never to emit any excrementitious matter *per anum* for years. In theſe, not only the chyle, but the excrementitious matter alſo, was abſorbed by the lacteals; and the excrement was afterwards thrown out of the body by other outlets, particularly by the ſkin: in conſequence of which, thoſe perſons have conſtantly that particular odour about them which diſtinguiſhes excrement. Now in theſe perſons, it is evident that the chyle and excrement, though mixed together, and even abſorbed together, did not act on each other; becauſe theſe perſons have been known to enjoy good health for years, which could not have been the caſe had the chyle been deſtroyed.

340
Uſe of bile.

7. It has been ſuppoſed by ſome that the decompoſition of the chyme, and the formation of chyle, is produced by the agency of the bile, which is poured out abundantly, and mixed with the chyme, ſoon after its entrance into the inteſtines. If this theory were true, no chyle could be formed whenever any accident prevented the bile from paſſing into the inteſtinal canal: but this is obviouſly not true; for frequent inſtances have occurred of perſons labouring under jaundice from the bile ducts being ſtopped, either by gallſtones or ſome other cauſe, ſo completely, that no bile could paſs into the inteſtines; yet theſe perſons have lived for a conſiderable time in that ſtate. Conſequently digeſtion, and therefore the formation of chyle, muſt be poſſible, independent of bile.

The principal uſe of the bile ſeems to be to ſeparate the excrement from the chyle, after both have been formed, and to produce the evacuation of the excrement out of the body. It is probable that theſe ſubſtances would remain mixed together, and that they would perhaps even be partly abſorbed together, were it not for the bile, which ſeems to combine with the excrement, and by this combination to facilitate its ſeparation from the chyle, and thus to prevent its abſorption. It alſo ſtimulates the inteſtinal canal, and cauſes it to evacuate its contents ſooner than it otherwiſe would do; for when there is a deficiency of bile, the body is conſtantly coſtive.

341
Of the excrementitious matter.

8. The excrement, then, which is evacuated *per anum*, conſiſts of all that part of the food and chyme which was not converted into chyle, entirely altered however from its original ſtate, partly by the decompoſition which it underwent in the ſtomach and inteſtines, and partly by its combination with bile. Accordingly we find in it many ſubſtances which did not exiſt at all in the food. Thus in the dung of cows and horſes there is found a very conſiderable quantity of benzoic acid. The excrements of animals have not yet been ſubjected to an accurate analyſis, though ſuch an analyſis would throw much light upon the nature of digeſtion. For if we knew accurately the ſubſtances which were taken into the body as food, and all the new ſubſtances which were formed by digeſtion; that is to ſay, the component parts of chyle and of excrement, and the variation which different kinds of food produce in the excrement, it would be a very conſiderable ſtep towards aſcertaining preciſely the changes produced on food by digeſtion, or, which is the ſame thing, towards aſcertaining exactly the phenomena of digeſtion. The only analyſis which has hitherto been made on human excrement is that of Homberg; and as it conſiſted merely in ſubjecting it to diſtillation, it is needleſs to give an account of it. Of late, as Mr Fourcroy informs us, the ſubject has been reſumed in France, and we may ſoon expect ſome very curious and important additions to our knowledge.

34[2]
Excre[ments] of fow[ls.]

Mr Vauquelin has already publiſhed an analyſis of the fixed parts of the excrements of fowls, and a compariſon of them with the fixed parts of the food; from which ſome very curious conſequences may be deduced.

He found that a hen devoured in ten days 11111.843 grains troy of oats. Theſe contained

136.509 gr. of phoſphat of lime,
219.548 ſilica,
———
356.057

During theſe ten days ſhe layed four eggs; the ſhells of which contained 98.776 gr. phoſphat of lime, and 453.417 gr. carbonat of lime. The excrements emitted during theſe ten days contained 175.529 gr. phoſphat of lime, 58.494 gr. of carbonate of lime, and 185.266 gr. of ſilica. Conſequently the fixed parts thrown out of the ſyſtem during theſe ten days amounted to

	Grains.	
	274.305	phoſphat of lime,
	511.911	carbonat of lime,
	185 266	ſilica,
Given out	971.482	
Taken in	356.057	
	615.425	

Conſequently the quantity of fixed matter given out of the ſyſtem in ten days exceeded the quantity taken in by 615.425 grains.

The ſilica taken in amounted to	219.548 gr.
That given out was only	185.266 gr.
Remains	34.282

Conſequently there diſappeared 34.282 grains of ſilica.

The phoſphat of lime taken in was	136.509 gr.
That given out was	274.305 gr.
	137.796

Conſequently

Conſequently there muſt have been formed, by digeſtion in this fowl, no leſs than 137.796 grains of phoſphat of lime, beſides 511.911 grains of carbonat. Conſequently lime (and perhaps alſo phoſphorus) is not a ſimple ſubſtance, but a compound, and formed of ingredients which exiſt in oat-ſeed, water, or air, the only ſubſtance to which the fowl had acceſs. Silica may enter into its compoſition, as a part of the ſilica had diſappeared; but if ſo, it muſt be combined with a great quantity of ſome other ſubſtance.*

Theſe conſequences are too important to be admitted without a very rigorous examination. The experiment muſt be repeated frequently, and we muſt be abſolutely certain that the hen has no acceſs to any calcareous earth, and that ſhe has not diminiſhed in weight; becauſe in that caſe ſome of the calcareous earth, of which part of her body is compoſed, may have been employed. This rigour is the more neceſſary, as it ſeems pretty evident, from experiments made long ago, that *ſome* birds at leaſt, cannot produce eggs unleſs they have acceſs to calcareous earth. Dr Fordyce found, that if the canary bird was not ſupplied with lime at the time of her laying, ſhe frequently died, from her eggs not coming forward properly.† He divided a number of theſe birds at the time of their laying eggs into two parties: to the one he gave a piece of old mortar, which the little animals ſwallowed greedily; they laid their eggs as uſual, and all of them lived: whereas many of the other party, which were ſupplied with no lime, died.‡

9. The inteſtines ſeldom or never are deſtitute of gaſes, which ſeem to be evolved during the proceſs of digeſtion; and may therefore, in part, be conſidered as excrementitious matter. The only perſon who has examined theſe gaſes with care, is Mr Jurine of Geneva. The reſult of his analyſis is as follows. He found in the ſtomach and inteſtines of a man who had been frozen to death, carbonic acid gas, oxygen gas, hydrogen gas, and azotic gas. The quantity of carbonic acid was greateſt in the ſtomach, and it diminiſhed gradually as the canal receded from the ſtomach; the proportion of oxygen gas was conſiderable in the ſtomach, ſmaller in the ſmall inteſtines, and ſtill ſmaller in the great inteſtines; the hydrogen and azotic gaſes, on the contrary, were leaſt abundant in the ſtomach, more abundant in the ſmall inteſtines, and moſt abundant in the larger inteſtines; the hydrogen gas was moſt abundant in the ſmall inteſtines. It is well known that the flatus diſcharged *per anum* is commonly carbonated hydrogen gas; ſometimes alſo it ſeems to hold ſulphur, or even phoſphorus in ſolution.§

10. The chyle, after it has been abſorbed by the lacteals, is carried by them into a pretty large veſſel, known by the name of *thoracic duct*. Into the ſame veſſel likewiſe is diſcharged a tranſparent fluid, conveyed by a ſet of veſſels which ariſe from all the cavities of the body. Theſe veſſels are called *lymphatics*, and the fluid which they convey is called *lymph*. In the thoracic duct, then, the chyle and the lymph are mixed together.

Very little is known concerning the nature of the *lymph*, as it is ſcarcely poſſible to collect it in any quantity. It is colourleſs, has ſome viſcidity, and is ſaid to be ſpecifically heavier than water. It is ſaid to be coagulable by heat; if ſo, it contains albumen; and, from its appearance, it probably contains gelatine. Its quantity is certainly conſiderable, for the lymphatics are very numerous. Functions of Animals.

345 And conveyed to the heart and lungs.

11. The chyle and lymph being thus mixed together, are conveyed directly into the blood veſſels. The effect produced by their union in the thoracic duct is not known, but neither the colour nor external properties of the chyle is altered. In man, and many other animals, the thoracic duct enters at the junction of the left ſubclavian and carotid veins, and the chyle is conveyed directly to the heart, mixed with the blood, which already exiſts in the blood veſſels. From the heart, the blood and chyle thus mixed together are propelled into the lungs, where they undergo farther changes.

346 Reſpiration

12. The abſolute neceſſity of *reſpiration*, or of ſomething analogous, is known to every one; and few are ignorant that in man, and hot blooded animals, the organ by which reſpiration is performed is the lungs. For a deſcription of the reſpiratory organs, we refer to the article Anatomy, *Encycl.* and the reader will find an account of the manner in which that function is performed in the article Physiology, *Encycl.* But what are the changes produced upon the blood and the chyle by reſpiration? What purpoſes does it ſerve to the animal? How comes it to be ſo indiſpenſably neceſſary for its exiſtence? Theſe are queſtions which can only be anſwered by a careful examination of the phenomena of reſpiration.

347 Requires oxygen gas.

It has been long known that an animal can only breathe a certain quantity of air for a limited time, after which it becomes the moſt deadly poiſon, and produces ſuffocation as effectually as the moſt noxious gas, or a total abſence of air. It was ſuſpected long ago that this change is owing to the abſorption of a part of the air; and Mayow made a number of very ingenious experiments in order to prove the fact. Dr Prieſtley and Mr Scheele demonſtrated, that the quantity of oxygen gas in atmoſpheric air is diminiſhed; and Lavoiſier demonſtrated, in 1776, that a quantity of carbonic acid gas, which did not previouſly exiſt in it, was found in air after it had been for ſome time reſpired. It was afterwards proved by Lavoiſier, and many other philoſophers, who confirmed and extended his facts, that no animal can live in air totally deſtitute of oxygen. Even fiſh, which do not ſenſibly reſpire, die very ſoon, if the water in which they live be deprived of oxygen gas. Frogs which can ſuſpend their reſpiration at pleaſure, die in about forty minutes, if the water in which they have been confined be covered over with oil.* Inſects and worms, as Vauquelin has proved, exhibit preciſely the ſame phenomena. They require oxygen gas as well as other animals, and die like them if they be deprived of it. They diminiſh the quantity of the oxygen gas in which they live, and give out, by reſpiration, the very ſame products as other animals. Worms, which are more retentive of life than moſt other animals, or at leaſt not ſo much affected by poiſonous gaſes, abſorb every particle of the oxygen gas contained in the air in which they are confined before they die. Mr Vauquelin's experiments were made on the gryllus viridiſſimus, the limax flavus, and helix pomatia.†

348 Changes produced by it.

The changes which take place during reſpiration are the following:

1. Part of the oxygen gas reſpired diſappears.

2. Carbonic

* Carradori, *Ann. de Chim.* xxix. 171.

† *Ann. de Chim.* xii. 278.

Functions of Animals.

2. Carbonic acid gas is emitted.

3. Water is emitted in the ftate of vapour.

The firft point is to afcertain exactly the amount of thefe changes. Though a great many experiments have been made on this fubject by different philofophers, the greateft confidence ought to be put in thofe of Lavoifier, both on account of his uncommon accuracy, and on account of the very complete apparatus which he always employed.

He put a guinea pig into 708.989 grains troy of oxygen, and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen gas now amounted only to 592.253 gr.

Confequently there had difappeared	116 736
The carbonic acid gas formed was	130.472
This was compofed of about	94.234
oxygen, and	36.238

of carbon. Confequently fuppofing, as Mr Lavoifier did, that the oxygen abforbed had been employed in the formation of the carbonic acid gas, there ftill remained to be accounted for 22.502 grains of oxygen which had difappeared. He fuppofed that this had been employed in the formation of water, a quantity of which had appeared. If fo, the water formed muft have amounted to 26.429 grains; which was compofed of 3.927 hydrogen, the reft oxygen.*

* Ann. de Chim. v. 261.

Since the water emitted was not actually afcertained, this experiment can only be confidered as an approximation to the truth. Accordingly that very ingenious philofopher contrived an apparatus to afcertain the quantity of oxygen gas abforbed by man, and the quantity of carbonic acid gas and water emitted by him during refpiration. This apparatus he had conftructed at an expence at leaft equal to L.500 fterling. The experiments were completed, and he was preparing them for publication, when, on the 8th of May 1794, he was beheaded by order of Robefpierre, after having in vain requefted a fortnight's delay to put his papers in order for the prefs. Thus perifhed, in the 51ft year of his age, the man who, if he had lived a few years longer, promifed fair to become the rival of Newton himfelf. Chemiftry, as a fcience, is deeply indebted to him. He faved it from that confufion into which the thoughtlefs ardour of many of his contemporaries were plunging it headlong: he arranged and connected and fimplified and explained the multitude of infulated facts, which had been accumulating with unexampled celerity; and which, had it not been for his happy arranging genius, might have retarded, inftead of advanced, the progrefs of the fcience. He reduced all the facts under a few fimple heads, and thus made them eafily remembered and eafily claffified. In a few years more, perhaps, he would have traced thefe general principles to their fources, eftablifhed the fcience on the completeft induction, and paved for his fucceffors a road as unerring as that which Sir Ifaac Newton formed in mechanical philofophy.

Mr Lavoifier's experiments have never been publifhed, but fortunately Mr de la Place has given us the refult of them.† He informs us that it was as follows: A man, at an average, confumes, in twenty-four hours, by refpiration, 32 48437 ounces troy of oxygen gas; that is to fay, that a quantity of oxygen gas, equal to that weight, difappears from the air which he refpires in twenty-four hours; that he gives out by refpiration, in the fame time, 15.73 oz. troy of carbonic acid gas, and 28.55 of water in the ftate of vapour.

† La Place's Eloge.

Total	44.28	*Oxygen.*
The carbonic acid gas is compofed of and 5.243 carbon. The water of and 4.2825 hydrogen.		10.486
		24.2675
Total of the oxygen emitted		34.75416
Total abforbed		32.48437
So that there is		2.3697916

ounces of oxygen emitted more than is abforbed by refpiration. Thus it appears that, by refpiration, the abfolute quantity of oxygen in the blood is diminifhed.

Dr Menzies found that a man, at a medium, draws in at every refpiration 43.77 cubic inches of air, and that $\frac{1}{20}$th of that quantity difappears. Confequently, according to him, at every refpiration 2.1885 cubic inches of oxygen gas are confumed. Now 2.1885 cubic inches of that gas amount to 0 68669 gr. troy. Suppofing, with Hales, that a man makes 1200 refpirations in an hour, the quantity of oxygen gas confumed in an hour, will amount to 824.028 grains, and in 24 hours to 19776.672 grains, or 41.2014 ounces troy. This quantity exceeds that found by Lavoifier confiderably; but the allowance of oxygen for every refpiration is rather too great. Indeed, from the nature of Dr Menzies's apparatus, it was fcarce poffible to meafure it accurately.

The quantity of water given out by refpiration, as determined by Hales, amounts in a day to 20.4 oz.;* but his method was not fufceptible of great accuracy. We may therefore, on the whole, confider Lavoifier's determination as by far the neareft to the truth of any that has been given.

* Veget. Stat. ii. 327.

There is, however, a very fingular anomaly, which becomes apparent when we compare his experiments on the refpiration of the guinea-pig with thofe on the refpiration of man.

The guinea-pig confumed in 24 hours 5.8368 oz. troy of oxygen gas, and emitted 6.5236 oz. of carbonic acid gas. Man, on the other hand, confumes in the fame time 32 48437 oz. of oxygen gas, and emits only 15.73 oz. of carbonic acid gas. The oxygen gas confumed by the pig is to the carbonic gas emitted as 1.00 : 1.12; whereas in man it is as 1.000 : 0.484. If we could depend upon the accuracy of each of thefe experiments, they would prove, beyond a doubt, that the changes produced by the refpiration of the pig are different, at leaft in degree, from thofe produced in man; but it is more than probable that fome miftake has crept into one or other of the experiments. We have more reafon to fufpect the firft, as it was made before 1778, at a time when a great many circumftances, neceffary to infure accuracy, were unknown to Lavoifier.

Such are the fubftances imbibed and emitted during refpiration. It ftill remains for us to determine what are the changes which it produces on the blood.

It has been long known that the blood which flows in the veins is of a dark reddifh purple colour, whereas the arterial blood is of a florid fcarlet colour. Lower obferved that the colour of the veinous blood was converted into that of arterial during its paffage through the tions imals. the lungs. No chyle can be diſtinguiſhed by its white colour in the blood after it has paſſed through the lungs. The changes, then, which take place upon the appearance of the blood are two: 1*ſt*, It acquires a florid red colour: 2*d*, The chyle totally diſappears. Now to what are theſe changes owing?

Lower himſelf knew that the change was produced by the air, and Mayow attempted to prove that it was by abſorbing a part of the air. But it was not till Dr Prieſtley diſcovered that veinous blood acquires a ſcarlet colour when put in contact with oxygen gas, and arterial blood a dark red colour when put in contact with hydrogen gas, or, which is the ſame thing, that

49 hypo- stoex- theſe ges. oxygen gas inſtantly gives veinous blood the colour of arterial; and hydrogen, on the contrary, gives arterial blood the colour of veinous blood: it was not till then that philoſophers began to attempt any thing like an explanation of the phenomena of reſpiration. Two explanations have been given; one or other of which muſt be true.

The firſt is, that the oxygen of the air, which diſappears, combines with a quantity of carbon and hydrogen given out by the blood in the lungs, and forms with it carbonic acid gas and water in vapour, which are thrown out along with the air expired.

The ſecond is, that the oxygen gas, which diſappears, combines with the blood as it paſſes thro' the lungs; and that, at the inſtant of this combination, there is ſet free from the blood a quantity of carbonic acid gas and of water, which are thrown out along with the air expired.

The firſt of theſe theories was originally formed by Lavoiſier and it was embraced by La Place, Crawford, Gren, and Girtanner, with a ſmall variation. Indeed it does not differ, except in detail, from the original hypotheſis of Dr Prieſtley, that the uſe of reſpiration is to rid the blood of phlogiſton; for if we ſubſtitute carbon and hydrogen for phlogiſton, the two theories preciſely agree. Mr Lavoiſier attempted not to prove its truth; he only tried to ſhew that the oxygen abſorbed correſponds exactly with the quantity of oxygen contained in the carbonic acid and the water emitted. This coincidence his own experiments have ſhewn not to hold; conſequently the theory is entirely deſtitute of proof, as far as the proof depends upon this coincidence.

The other hypotheſis was propoſed by Mr de la Grange, and afterwards ſupported and illuſtrated by Mr Haſſenfratz.

350 ſts of ration ained. In order to diſcover what the real effects of reſpiration are, let us endeavour to ſtate accurately the phenomena as far as poſſible.

In the *firſt* place, we are certain, from the experiments of Prieſtley, Girtanner, and Haſſenfratz, that when veinous blood is expoſed to oxygen gas confined over it, the blood inſtantly aſſumes a ſcarlet colour, and the gas is diminiſhed in bulk; therefore part of the gas has been abſorbed. We may conſider it as certain, then, that when the colour of veinous blood is changed into arterial, ſome oxygen gas is abſorbed.‡

‡ ...n. de ...v. vii.

In the *ſecond* place, no chyle can be diſcovered in the blood after it has paſſed through the lungs. Therefore the *white colour* of the chyle at leaſt, is deſtroyed by reſpiration, and it aſſumes a red colour. Now if the red colour of the blood be owing to iron, as many have ſuppoſed, this change of colour is a demonſtration that oxygen has combined with the iron; for we have ſeen already, that iron, if it exiſts in chyle, as it probably does, is in the ſtate of a white oxyd. Conſequently, when converted into a red oxyd, it muſt abſorb oxygen. Even though iron be not the colouring matter of the blood, it would ſtill be probable that the change of colour of the chyle depends on the fixation of oxygen; for Berthollet and Fourcroy have ſhewn that in ſeveral inſtances ſubſtances acquire a red colour by that proceſs. Functions of Animals.

We may conſider it as proved, then, that oxygen enters the blood as it paſſes through the lungs.

In the *third* place, when arterial blood is put in contact with azotic gas or carbonic acid gas, it gradually aſſumes the dark colour of veinous blood, as Dr Prieſtley found.* The ſame philoſopher alſo obſerved that arterial blood acquired the colour of veinous blood when placed in vacuo.† Conſequently this alteration of colour is owing to ſome change which takes place in the blood itſelf, independent of any external agent.

* *Prieſtley*, iii. 563.

† *Ibid*, and *Ann. de Chim.* ix. 269.

The arterial blood becomes much more rapidly and deeply dark coloured when it is left in contact with hydrogen gas placed above it.‡ We muſt ſuppoſe therefore that the preſence of this gas accelerates and increaſes the change, which would have taken place upon the blood without any external agent.

‡ *Fourcroy, Ann. de Chim.* vii. 149.

If arterial blood be left in contact with oxygen gas, it gradually aſſumes the ſame dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer reſtore its ſcarlet colour.§ Therefore it is only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occaſions the dark colour, the blood loſes the power of being affected by oxygen.

§ *Ibid.* ix. 268.

Mr Haſſenfratz poured into veinous blood a quantity of oxy-muriatic acid; the blood was inſtantly decompoſed, and aſſumed a deep and almoſt black colour. When he poured common muriatic acid into blood, the colour was not altered.‖ Now oxy-muriatic acid has the property of giving out its oxygen readily; conſequently the black colour was owing to the inſtant combination of a part of the blood with oxygen.

‖ *Ibid.*

The facts therefore lead us to conclude, with La Grange and Haſſenfratz, that during reſpiration the oxygen, which diſappears, enters the blood; that during the circulation this oxygen combines with a certain part of the blood; and that the veinous colour is owing to this new combination. We muſt conclude, too, that the ſubſtance which cauſes this dark colour leaves the blood during its circulation thro' the lungs, otherwiſe it could not be capable of aſſuming the florid colour. Now we know what the ſubſtances are which are emitted during reſpiration; they are water and carbonic acid gas. It muſt be to the gradual combination of oxygen, then, during the circulation, with hydrogen and carbon, that the colour of veinous blood is owing. And ſince the ſame combination takes place every time that the blood paſſes through the lungs, we muſt conclude, that it is only a part of the hydrogen and carbon which is acted upon each time. Let us now attempt, with theſe data, to form ſome notion of the decompoſition which goes on during the circulation of the blood.

351 Contributes to the formation of blood, It is probable that during a conſiderable part of the day, there is a conſtant influx of chyle into the blood and we are certain that lymph is conſtantly flowing into

Functions of Animals.

to it. Now it appears, from the most accurate observations hitherto made, that neither chyle nor lymph contain fibrina, which forms a very conspicuous part of the blood. This fibrina is employed to supply the waste of the muscles, the most active parts of the body, and therefore, in all probability, requiring the most frequent supply. Nor can it be doubted that it is employed for other useful purposes. The quantity of fibrina in the blood, then, must be constantly diminishing, and therefore new fibrina must be constantly formed. But the only substances out of which it can be formed are the chyle and lymph, neither of which contain it. There must therefore be a continual decomposition of the chyle and lymph going on in the blood-vessels, and a continual new formation of fibrina. Other substances also may be formed; but we are certain that this *must* be formed there, because it does not exist previously. Now, one great end of respiration must undoubtedly be to assist this decomposition of chyle and complete formation of blood.

It follows, from the experiments of Fourcroy formerly enumerated, that fibrina contains more azot, and less hydrogen and carbon, than any of the other ingredients of the blood, and consequently also than any of the ingredients of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impossible to say: we are not sufficiently acquainted with the subject to be able to explain the process. But we can see at least, that carbon and hydrogen must be abstracted from that part of the chyle which is to be converted into fibrina: And we know, that these substances are actually thrown out by respiration. We may conclude, then, that *one* use of the oxygen absorbed is, to abstract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in such proportions, that the remainder becomes fibrina: therefore one end of respiration is to form fibrina. Doubtless the other ingredients of the blood are also new modified, though we know too little of the subject to throw any light upon it.

35 Produces animal heat;

13. But the complete formation of blood is not the only advantage gained by respiration: the *temperature* of all animals depends upon it. It has been long known, that those animals which do not breathe have a temperature but very little superior to the medium in which they live. This is the case with fishes and many insects. Man, on the contrary, and quadrupeds which breathe, have a temperature considerably higher than the atmosphere: that of man is 98°. Birds, who breathe in proportion a still greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

These facts are sufficient to demonstrate, that the heat of animals depends upon respiration. But it was not till Dr Black's doctrine of latent heat became known to the world, that any explanation of the cause of the temperature of breathing animals was attempted. That illustrious philosopher, whose discoveries form the basis upon which all the scientific part of chemistry has been reared, saw at once the light which his doctrine of latent heat threw upon this part of physiology, and he applied it very early to explain the temperature of animals.

According to him, part of the latent heat of the air inspired becomes sensible; and of course, the temperature of the lungs, and the blood that passes through them, must be raised; and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanswerable objection: for if it were true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually as the distance from the lungs increases; which is not true. The theory, in consequence, was abandoned even by Dr Black himself; at least he made no attempt to support it.

Lavoisier and Crawford, who considered all the changes operated by respiration as taking place in the lungs, accounted for the origin of the animal heat almost precisely in the same manner with Dr Black. According to them, the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitted by the blood. During this combination, the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only sufficient to support the temperature of the body, but also to carry off the new formed water in the state of vapour, and to raise considerably the temperature of the air inspired. According to these philosophers, then, the whole of the caloric which supports the temperature of the body is evolved in the lungs. Their theory accordingly was liable to the same objection with Dr Black's; but they obviated it in the following manner: Dr Crawford found, that the specific caloric of arterial blood was 1.0300, while that of veinous blood was only 0.8928. Hence he concluded, that the instant veinous blood is changed into arterial blood, its specific caloric increases; consequently it requires an additional quantity of caloric to keep its temperature as high as it had been while veinous blood. This addition is so great, that the whole new caloric evolved is employed: therefore the temperature of the lungs must necessarily remain the same as that of the rest of the body. During the circulation, arterial blood is gradually converted into veinous; consequently its specific caloric diminishes, and it must give out heat. This is the reason that the temperature of the extreme parts of the body does not diminish.

This explanation is certainly ingenious; but it is not quite satisfactory; for the difference in the specific caloric, granting it to be accurate, is too small to account for the great quantity of heat which must be evolved. It is evident that it must fall to the ground altogether, provided, as we have seen reason to suppose, the carbonic acid gas and water be not formed in the lungs, but during the circulation.

Since the oxygen enters the blood, and combines with it in the state of gas, it is evident that it will only part at first with some of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas and the water. For the reason that the carbonic acid leaves the blood at the instant that the oxygen gas enters it, seems to be this: The oxygen gas combines with the blood, and part of its caloric unites at the same instant to the carbonic acid, and converts it into gas: another portion converts the water into vapour. The rest of the caloric is evolved during the circulation when the oxygen combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs seems not only sufficient to carry off the carbonic acid and water, which the diminution

nution of the ſpecific caloric (if it really take place) muſt facilitate; but it ſeems alſo to raiſe the temperature of the blood a little higher than it was before. For Mr John Hunter conſtantly found, that the heat of the heart in animals was a degree higher than any other part of the body which he examined. Now this could ſcarcely happen, unleſs the temperature of the blood were ſomewhat raiſed during reſpiration.

53 Thus we have ſeen two uſes which reſpiration ſeems to ſerve. The firſt is the completion of blood by the formation of fibrina; the ſecond is the maintaining of the temperature of the body at a particular ſtandard, notwithſtanding the heat which it is continually giving out to the colder ſurrounding bodies. But there is a third purpoſe, which explains why the animal is killed ſo ſuddenly when reſpiration is ſtopped. The circulation of the blood is abſolutely neceſſary for the continuance of life. Now the blood is circulated in a great meaſure by the alternate contractions of the heart. It is neceſſary that the heart ſhould contract regularly, otherwiſe the circulation could not go on. But the heart is ſtimulated to contract by the blood: and unleſs blood be made to undergo the change produced by reſpiration, it ceaſes almoſt inſtantaneouſly to ſtimulate. As the blood receives oxygen in the lungs, we may conclude that the preſence of oxygen is neceſſary to its ſtimulating power.*

14. Thus we have reaſon to ſuppoſe, that chyle and lymph are converted into blood during the circulation; and that the oxygen gas ſupplied by reſpiration is one of the principal agents in this change. But beſides the lungs and arteries, there is another organ, the ſole uſe of which is alſo to produce ſome change or other in the blood which renders it more complete, and more proper for the various purpoſes to which it is applied. This organ is the *kidney.*

For the ſtructure of the kidneys, which in man and quadrupeds are two in number, we refer to ANATOMY, *Encycl.* A very great proportion of blood paſſes through them; indeed, we have every reaſon to conclude, that the whole of the blood paſſes through them very frequently.

Theſe organs ſeparate the urine from the blood, to be afterwards evacuated without being applied to any purpoſe uſeful to the animal.

The kidneys are abſolutely neceſſary for the continuance of the life of the animal; for it dies very ſpeedily when they become by diſeaſe unfit to perform their functions; therefore the change which they produce in the blood is a change neceſſary for qualifying it to anſwer the purpoſes for which it is intended.

As the urine is immediately excreted, it is evident that the change which the kidneys perform is intended ſolely for the ſake of the blood. It is not merely the abſtraction of a quantity of water and of ſalts, accumulated in the blood, which the kidney performs. A chemical change is certainly produced, either upon the whole blood, or at leaſt on ſome important part of it; for there are two ſubſtances found in the urine which do not exiſt in the blood. Theſe two ſubſtances are urea and uric acid. They are formed, therefore, in the kidneys; and as they are thrown out, after being formed, without being applied to any uſeful purpoſe, they are certainly not formed in the kidneys for their own ſake. Some part of the blood, then, muſt be decompoſed in the kidney, and a new ſubſtance, or new ſubſtances, muſt be formed; and the urea and uric acid muſt be formed at the ſame time, in conſequence of the combined action of the affinities which produce the change on the blood; and being uſeleſs, they are thrown out, together with a quantity of water and ſalts, which in all probability, were uſeful in bringing about the changes which take place in the arteries and in the kidneys, but which are no longer of any ſervice after theſe changes are brought about.

The changes operated upon the blood in the kidneys are hitherto altogether unknown; but they muſt be important.

Provided the method of analyſing animal ſubſtances were ſo far perfected as to admit of accurate concluſions, conſiderable light might be thrown upon this ſubject, by analyſing with care a portion of blood from the emulgent vein and artery ſeparately, and aſcertaining preciſely in what particulars they differ from each other.

15. Thus we have ſeen that the principal changes which the blood undergoes, as far at leaſt as we are at preſent acquainted with them, take place in the lungs, in the kidneys, and in the arteries. In the lungs, a quantity of water and carbonic acid gas is emitted from the blood, and in the kidney the urine is formed and ſeparated from it. There ſeems alſo to be ſomething thrown out from the blood during its circulation in the arteries, at leaſt through thoſe veſſels which are near the ſurface of the body: For it is a fact, that certain ſubſtances are conſtantly emitted from the ſkins of animals. Theſe ſubſtances are known in general by the name of *perſpirable matter,* or *perſpiration.* They have a great reſemblance to what is emitted in the lungs; which renders it probable, that they are both owing to the ſame cauſe; namely, to the decompoſition produced in the blood by the effects of reſpiration. They conſiſt chiefly of water in a ſtate of vapour, carbon, and oil.

The quantity of aqueous vapour differs very conſiderably, according to circumſtances. It has been ſhewn to be greateſt in hot weather, and in hot climates, and after great exerciſe; and its relation to the quantity of urine has been long known. When the aqueous vapour perſpired is great, the quantity of urine is ſmall, and *vice verſa.*

The moſt accurate experiments on this matter that we have ſeen are thoſe of Mr Cruickſhank. He put his hand into a glaſs veſſel, and luted its mouth at his wriſt by means of a bladder. The interior ſurface of the veſſel became gradually dim, and drops of water trickled down. By keeping his hand in this manner for an hour, he collected 30 grains of a liquid, which poſſeſſed all the properties of pure water.* On repeating the ſame experiment at nine in the evening (thermometer 62°), he collected only 12 grains. The mean of theſe is 21 grains. But as the hand is more expoſed than the trunk of the body, it is reaſonable to ſuppoſe that the perſpiration from it is greater than that from the hand. Let us therefore take 30 grains per hour as the mean; and let us ſuppoſe, with Mr Cruikſhank, that the hand is $\frac{1}{60}$th of the ſurface of the body. The perſpiration in an hour would amount to 1800 grains, and in 24 hours to 43200 grains, or 7 pounds 6 ounces troy.

Functions of Animals.

He repeated the experiment again after hard exercife, and collected in an hour 48 grains of water.* He found alfo, that this aqueous vapour pervaded his ftocking without difficulty; and that it made its way through a fhamoy leather glove, and even through a leather boot, though in much fmaller quantity than when the leg wanted that covering.†

* *On Infenfible Perfpiration*, p. 70.
† *Ibid.* p. 82.

It is not difficult to fee why the quantity of watery vapour diminifhes with cold. When the furface of the body is expofed to a cold temperature, the capacity of the cutaneous veffels diminifhes, and confequently the quantity which flows through them muft decreafe.

When the temperature, on the other hand, is much increafed, either by being expofed to a hot atmofphere, or by violent exercife, the perfpired vapour not only increafes in quantity, but even appears in a liquid form. This is known by the name of *fweat*. In what manner fweat is produced, is not at prefent known; but we can fee a very important fervice which it performs to the animal.

No fooner is it thrown upon the furface of the fkin than it begins to evaporate. But the change into vapour requires heat; accordingly a quantity of heat is abforbed, and the temperature of the animal is lowered. This is the reafon that animals can endure to remain for fome time in a much higher temperature without injury than could have been fuppofed.

The experiments of Tillet, and the ftill more decifive experiments of Fordyce and his affociates, are well known. These gentlemen remained a confiderable time in a temperature exceeding the boiling point of water.

357 Carbon,

Befides water, it cannot be doubted that *carbon* is alfo emitted from the fkin; but in what ftate, the experiments hitherto made do not enable us to decide. Mr Cruikfhank found, that the air of the glafs veffel in which his hand and foot had been confined for an hour, contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid.* And Mr Jurine found, that air which had remained for fome time in contact with the fkin, confifted almoft entirely of carbonic acid gas.† The fame conclufion may be drawn from the experiments of Ingenhoufz and Milly.‡

* *Ibid.* p. 70 and 81.
† *Enc. Meth. Med.* i. p. 515.
‡ *Ibid*, p. 511.

Now it is evident, that the carbonic acid gas which appeared during Mr Cruikfhank's experiment, did not previoufly exift in the glafs veffel; confequently it muft have either been tranfmitted ready formed through the fkin, or formed during the experiment by the abforption of oxygen gas, and the confequent emiffion of carbonic acid gas. The experiments of Mr Jurine do not allow us to fuppofe the firft of thefe to be true; for he found, that the quantity of air allowed to remain in contact with the fkin did not increafe. Confequently the appearance of the carbonic acid gas muft be owing, either to the emiffion of carbon, which forms carbonic acid gas by combining with the oxygen gas of the air, or to the abforption of oxygen gas, and the fubfequent emiffion of carbonic acid gas; precifely in the fame manner, and for the fame reafon, that thefe fubftances are emitted by the lungs. The laft is the more probable opinion; but the experiments hitherto made do not enable us to decide.

358 And an oily matter.

Befides water and carbon, or carbonic acid gas, the fkin emits alfo a particular odorous fubftance. That every animal has a peculiar fmell, is well known: the dog can difcover his mafter, and even trace him to a diftance by the fcent. A dog, chained fome hours after his mafter had fet out on a journey of fome hundred miles, followed his footfteps by the fmell, and found him on the third day in the midft of a crowd.* But it is needlefs to multiply inftances of this fact; they are too well known to every one. Now this fmell muft be owing to fome peculiar matter which is conftantly emitted; and this matter muft differ fomewhat either in quantity or fome other property, as we fee that the dog eafily diftinguifhes the individual by means of it. Mr Cruikfhank has made it probable that this matter is an oily fubftance; or at leaft that there is an oily fubftance emitted by the fkin. He wore repeatedly, night and day for a month, the fame veft of fleecy hofiery during the hotteft part of the fummer. At the end of this time he always found a oily fubftance accumulated in confiderable maffes on the nap of the inner furface of the veft, in the form of black tears. When rubbed on paper, it makes it tranfparent, and hardens on it like greafe. It burns with a white flame, and leaves behind it a charry refiduum.†

* *Cruikfhank*, ibid. p. 93.
† *Ibid.* p. 92.

It has been fuppofed that the fkin has the property of *abforbing moifture* from the air; but this opinion has not been confirmed by experiments, but rather the contrary.

359 Whether the fkin abforbs moifture,

The chief arguments in favour of the abforption of the fkin, have been drawn from the quantity of moifture difcharged by urine being, in fome cafes, not only greater than the whole drink of the patient, but even than the whole of his drink and food. But it ought to be remembered that, in diabetes, the difeafe here alluded to, the weight of the body is continually diminifhing, and therefore part of it muft be conftantly thrown off. Befides, it is fcarcely poffible in that difeafe to get an accurate account of the food fwallowed by the patients; and in thofe cafes where very accurate accounts have been kept, and where deception was not fo much practifed, the urine was found not to exceed the quantity of drink.* In a cafe of diabetes, related with much accuracy by Dr Gerard, the patient was bathed regularly during the early part of the difeafe in warm water, and afterwards in cold water: he was weighed before and after bathing, and no fenfible difference was ever found in his weight.† Confequently, in that cafe, the quantity abforbed, if any, muft have been very fmall.

* See *Rollo on Diabetes*.
† *Ibid*, ii. 73.

It is well known, that thirft is much alleviated by cold bathing. By this plan, Captain Bligh kept his men cool and in good health during their very extraordinary voyage acrofs the South Sea. This has been confidered as owing to the abforption of water by the fkin. But Dr Currie had a patient who was wafting faft for want of nourifhment, a tumor in the œfophagus preventing the poffibility of taking food, and whofe thirft was always alleviated by bathing; yet no fenfible increafe of weight, but rather the contrary, was perceived after bathing. It does not appear, then, that in either of thefe cafes water was abforbed.

Farther, Seguin has fhewn that the fkin does not abforb water during bathing, by a ftill more complete experiment: He diffolved fome mercurial falt in water, and found that the mercury produced no effect upon a perfon that bathed in the water, provided no part of the ctions nimals. the cuticle was injured; but upon rubbing off a portion of the cuticle, the mercurial ſolution was abſorbed, and the effects of the mercury became evident upon the body. Hence it follows irreſiſtibly, that water, at leaſt in the ſtate of *water*, is not abſorbed by the ſkin when the body is plunged into it, unleſs the cuticle be firſt removed.

60 ny ·ſub- e. This may perhaps be conſidered as a complete proof that no ſuch thing as abſorption is performed by the ſkin; and that therefore the appearance of carbonic acid gas, which takes place when air is confined around the ſkin, muſt be owing to the emiſſion of carbon. But it ought to be conſidered, that although the ſkin cannot abſorb water, this is no proof that it cannot abſorb other ſubſtances; particularly, that it cannot abſorb oxygen gas, which is very different from water. It is well known, that water will not paſs through bladders, at leaſt for ſome time; yet Dr Prieſtley found that veinous blood acquired the colour of arterial blood from oxygen gas, as readily when theſe ſubſtances were ſeparated by a bladder as when they were in actual contact. He found, too, that when gaſes were confined in bladders, they gradually loſt their properties. It is clear from theſe facts, that oxygen gas can pervade bladders; and if it can pervade them, why may it not alſo pervade the cuticle? Nay, farther, we know from the experiments of Cruikſhank, that the vapour perſpired paſſes through leather, even when prepared ſo as to keep out moiſture, at leaſt for a certain time. It is poſſible, then, that water, when in the ſtate of vapour, or when diſſolved in air, may be abſorbed, although water, while in the ſtate of water, may be incapable of pervading the cuticle. The experiments, then, which have hitherto at leaſt been made upon the abſorption of the ſkin, are altogether inſufficient to prove that air and vapour cannot pervade the cuticle; provided at leaſt there be any facts to render the contrary ſuppoſition probable.

Now that there are ſuch facts cannot be denied. We ſhall not indeed produce the experiment of Van Mons as a fact of that kind, becauſe it is liable to objections, and at beſt is very undeciſive. Having a patient under his care who, from a wound in the throat, was incapable for ſeveral days of taking any nouriſhment, he kept him alive during that time, by applying to the ſkin in different parts of the body, ſeveral times a day, a ſponge dipt in wine or ſtrong ſoup.* A fact mentioned by Dr Watſon is much more important, and much more deciſive. A lad at Newmarket, who had been almoſt ſtarved in order to bring him down to ſuch a weight as would qualify him for running a horſe race, was weighed in the morning of the race day; he was weighed again juſt before the race began, and was found to have gained 30 ounces of weight ſince the morning; yet in the interval he had only taken a ſingle glaſs of wine. Here abſorption muſt have taken place, either by the ſkin, or lungs, or both. The difficulties in either caſe are the ſame; and whatever renders abſorption by one probable, will equally ſtrengthen the probability that abſorption takes place by the other (R).

il. vi.

16. We have now ſeen the proceſs of digeſtion, and the formation of blood, as far at leaſt as we are acquainted with it. But to what purpoſes is this blood employed, which is formed with ſo much care, and for the formation of which ſo great an apparatus has been provided? It anſwers two purpoſes. The parts of which the body is compoſed, bones, muſcles, ligaments, membranes, &c. are continually changing. In youth they are increaſing in ſize and ſtrength, and in mature age they are continually acting, and conſequently continually liable to waſte and decay. They are often expoſed to accidents, which render them unfit for performing their various functions; and even when no ſuch accident happens, it ſeems neceſſary for the health of the ſyſtem that they ſhould be every now and then renewed. Materials therefore muſt be provided for repairing, increaſing, or renewing all the various organs of the body. Phoſphat of lime and gelatine for the bones, fibrina for the muſcles, albumen for the cartilages and membranes, &c. Accordingly all theſe ſubſtances are laid up in the blood; and they are drawn from that fluid as from a ſtorehouſe whenever they are required. The proceſs by which the different parts of the blood are made part of the various organs of the body is called *aſſimilation*. Functions of Animals. 361 Blood ſupplies the waſte of the ſyſtem.

362 Aſſimilation. Over the nature of aſſimilation the thickeſt darkneſs ſtill hangs; there is no key to explain it, nothing to lead us to the knowledge of the inſtruments employed. Facts, however, have been accumulated in ſufficient numbers to put the exiſtence of the proceſs beyond the reach of doubt. The healing, indeed, of every fractured bone, and every wound of the body, is a proof of its exiſtence, and an inſtance of its action.

363 Every aſſimilating organ produces a peculiar change, Every organ employed in aſſimilation has a peculiar office; and it always performs this office whenever it has materials to act upon, even when the performance of it is contrary to the intereſt of the animal. Thus the ſtomach always converts food into chyme, even when the food is of ſuch a nature that the proceſs of digeſtion will be retarded rather than promoted by the change. If warm milk, for inſtance, or warm blood, be thrown into the ſtomach, they are always decompoſed by that organ, and converted into chyme; yet theſe ſubſtances are much more nearly aſſimilated to the animal before the action of the ſtomach than after it. The ſame thing happens when we eat animal food.

364 And no other change. On the other hand, a ſubſtance introduced into an organ employed in aſſimilation, if it has undergone preciſely the change which that organ is fitted to produce, is not acted upon by that organ, but paſſed on unaltered to the next aſſimilating organ. Thus it is the office of the inteſtines to convert chyme into chyle. Accordingly, whenever chyme is introduced into the inteſtines, they perform their office, and produce the uſual change; but if chyle itſelf be introduced into the inteſtines, it is abſorbed by the lacteals without alteration. The experiment, indeed, has not been tried with true chyle, becauſe it is ſcarce poſſible to procure it in ſufficient quantity; but when milk, which reſembles chyle pretty accurately, is thrown into the jejunum, it is abſorbed unchanged by the lacteals.*

* Fordyce on Digeſtion, p. 189.

Again,

(R) The Abbé Fontana alſo found, that after walking in moiſt air for an hour or two, he returned home ſome ounces heavier than he went out, notwithſtanding he had ſuffered conſiderable evacuation from a briſk purge purpoſely taken for the experiment. This increaſe, indeed, might be partly accounted for by the abſorption of moiſture by his clothes.

Functions of Animals.

Again, the office of the blood veſſels, as aſſimilating organs, is to convert chyle into blood. Chyle, accordingly, cannot be introduced into the arteries without undergoing that change; but *blood* may be introduced from another animal without any injury, and conſequently without undergoing any change. This experiment was firſt made by Lower, and it has ſince been very often repeated.

Alſo, if a piece of freſh muſcular fleſh be applied to the muſcle of an animal, they adhere and incorporate without any change, as has been ſufficiently eſtabliſhed by the experiments of Mr J. Hunter. And Buvina has aſcertained, that freſh bone may, in the ſame manner, be engrafted on the bones of animals of the ſame or of different ſpecies.†

† *Phil. Mag.* vi. 308.

In ſhort, it ſeems to hold, at leaſt as far as experiments have hitherto been made, that foreign ſubſtances may be incorporated with thoſe of the body, provided they be preciſely of the ſame kind with thoſe to which they are added, whether fluid or ſolid. Thus chyle may be mixed with chyle, blood with blood, muſcle with muſcle, and bone with bone. The experiment has not been extended to the other animal ſubſtances, the nerves, for inſtance; but it is extremely probable that it would hold with reſpect to them alſo.

On the other hand, when ſubſtances are introduced into any part of the body which are not the ſame with that part, nor the ſame with the ſubſtance upon which that part acts; provided they cannot be thrown out readily, they deſtroy the part, and perhaps even the animal. Thus foreign ſubſtances introduced into the blood very ſoon prove fatal; and introduced into wounds of the fleſh or bones, they prevent theſe parts from healing.

365 Their power limited.

Although the different aſſimilating organs have the power of changing certain ſubſtances into others, and of throwing out the uſeleſs ingredients, yet this power is not abſolute, even when the ſubſtances on which they act are proper for undergoing the change which the organs produce. Thus the ſtomach converts food into chyme, the inteſtines chyme into chyle, and the ſubſtances which have not been converted into chyle are thrown out of the body. If there happen to be preſent in the ſtomach and inteſtines any ſubſtance which, though incapable of undergoing the changes, at leaſt, by the action of the ſtomach and inteſtines, yet has a ſtrong affinity, either for the whole chyme and chyle, or for ſome particular part of it, and no affinity for the ſubſtances which are thrown out, that ſubſtance paſſes along with the chyle, and in many caſes continues to remain chemically combined with the ſubſtance to which it is united in the ſtomach, even after that ſubſtance has been completely aſſimilated, and made a part of the body of the animal. Thus there is a ſtrong affinity between the colouring matter of madder and phoſphat of lime. Accordingly, when madder is taken into the ſtomach, it combines with the phoſphat of lime of the food, paſſes with it through the lacteals and blood veſſels, and is depoſited with it in the bones, as was proved by the experiments of Duhamel. In the ſame manner muſk, indigo, &c. when taken into the ſtomach, make their way into many of the ſecretions.

Theſe facts ſhew us, that aſſimilation is a chemical proceſs from beginning to end; that all the changes are produced according to the laws of chemiſtry; and that we can even derange the regularity of the proceſs by introducing ſubſtances whoſe mutual affinities are too ſtrong for the organs to overcome.

366 Aſſimilation a chemical proceſs;

It cannot be denied, then, that the aſſimilation of food conſiſts merely in a certain number of chemical decompoſitions which that food undergoes, and the conſequent formation of certain new compounds. But are the *agents* employed in aſſimilation merely chemical agents? We cannot produce any thing like theſe changes on the food out of the body, and therefore we muſt allow that they are the conſequence of the action of the animal organs. But this action, it may be ſaid, is merely the ſecretion of particular juices, which have the property of inducing the wiſhed for change upon the food; and this very change would be produced out of the body, provided we could procure theſe ſubſtances, and apply them in proper quantity to the food. If this ſuppoſition be true, the ſpecific action of the veſſels conſiſts in the ſecretion of certain ſubſtances; conſequently the cauſe of this ſecretion is the *real* agent in aſſimilation. Now, can the *cauſe* of this ſecretion be ſhewn to be merely a chemical agent? Certainly not. For in the ſtomach, where only this ſecretion can be ſhewn to exiſt, it is not always the ſame, but varies according to circumſtances. Thus eagles at firſt cannot digeſt grain, but they may be brought to do it by perſiſting in making them uſe it as food. On the contrary, a lamb cannot at firſt digeſt animal food, but habit will alſo give it this power. In this caſe, it is evident that the gaſtric juice changes according to circumſtances. Now this is ſo far from being a caſe of a chemical law, that it is abſolutely incompatible with every ſuch law. The agent in aſſimilation, then, is not a chemical agent, but one which acts upon different principles. It is true, indeed, that every ſtep in the proceſs is chemical; but the agent which regulates theſe chemical proceſſes, which prevents them from acting, except in particular circumſtances and on particular ſubſtances, and modifies this action according to circumſtances, is not a mere chemical agent, but endowed with very different properties.

367 But the agent not chemical.

The preſence and power of this agent will be ſtill more evident, if we conſider the immunity of the ſtomach of the living animal during the proceſs of digeſtion. The ſtomach of animals is as fit for food as any other ſubſtance. The gaſtric juice, therefore, muſt have the ſame power of acting on it, and of decompoſing it, that it has of acting on other ſubſtances; yet it is well known that the ſtomach is not affected by digeſtion while the animal retains life; though, as Mr Hunter aſcertained, the very gaſtric juice which the living ſtomach ſecretes often diſſolves the ſtomach itſelf after death. Now what is the power which prevents the gaſtric juice from acting on the ſtomach during life? Certainly neither a chemical nor mechanical agent, for theſe agents muſt ſtill retain the ſame power after death. We muſt, then, of neceſſity conclude, that there exiſts in the animal an agent very different from chemical and mechanical powers, ſince it controuls theſe powers according to its pleaſure. Theſe powers therefore in the living body are merely the ſervants of this ſuperior agent, which directs them ſo as to accompliſh always one particular end. This agent ſeems to regulate the chemical powers, chiefly by bringing only certain ſubſtances together which are to be decompoſed, and by keeping at a diſtance thoſe ſubſtances which would interfere with, or diminiſh, or ſpoil the product, or injure

 injure the organ. And we fee that this feparation is always attended to even when the fubftances are apparently mixed together. For the very fame products are not obtained which would be obtained by mixing the fame fubftances together out of the body that are produced by mixing them in the body; confequently all the fubftances are not left at full liberty to obey the laws of their mutual affinities. The fuperior agent, however, is not able to exercife an unlimited authority over the chemical powers; fometimes they are too ftrong for it: fome fubftances accordingly, as madder, make their way into the fyftem; while others, as arfenic, decompofe and deftroy the organs of the body themfelves.

But it is not in digeftion alone that this fuperior agent makes the moft wonderful difplay of its power; it is in the laft part of affimilation that our admiration is moft powerfully excited. How comes it that the precife fubftances wanted are always carried to every organ of the body? How comes it that fibrina is always regularly depofited in the mufcles, and phofphat of lime in the bones? And what is ftill more unaccountable, how comes it that prodigious quantities of fome one particular fubftance are formed and carried to a particular place in order to fupply new wants which did not before exift? A bone, for example, becomes difeafed and unfit for the ufe of the animal; a new bone therefore is formed in its place, and the old one is carried off by the abforbents. In order to form this new bone, large quantities of phofphat of lime are depofited in a place where the fame quantity was not before neceffary. Now, who informs this agent that an unufual quantity of phofphat of lime is neceffary, and that it muft be carried to that particular place? Or granting, as is moft probable, that the phofphat of lime of the old bone is partly employed for this purpofe, who taught this agent that the old bone muft be carried off, new modelled, and depofited, and affimilated anew? The fame wonders take place during the healing of every wound, and the renewing of every difeafed part.

Thefe operations are incompatible with the fuppofition that the body of animals is a mere chemical and mechanical machine; and demonftrate the prefence of fome agent befides, which acts according to very different laws.

But neither in this cafe is the power of this agent over the chemical agents, which are employed, abfolute. We may prevent a fractured bone from healing by giving the patient large quantities of acids. And unlefs the materials for the new wanted fubftances be fupplied by the food, they cannot, in many cafes, be formed at all. Thus the canary bird cannot complete her eggs unlefs fhe be furnifhed with lime.

It is evident that the fupreme agent of the animal body, whatever that agent may be, acts according to fixed laws; and that when thefe laws are oppofed by thofe which are more powerful, it cannot overcome them. Thefe laws clearly indicate defign; and the agent has the power of modifying them fomewhat according to circumftances. Thus more phofphat of lime is fent to a limb which requires a new bone, and more lime than ufual is taken into the fyftem when the hen is laying eggs. Defign and contingency are confidered by us as infallible marks of confcioufnefs and intelligence. That they are infallible marks of the agency of mind is certain; but that they are in all cafes the proofs of immediate confcioufnefs and intelligence, as the Stahlians fuppofed, cannot be affirmed without running into inconfiftencies. For we ourfelves are not confcious of thefe operations which take place during *affimilation*.

To fay that a being can act with defign without intelligence, we allow to be a flat contradiction, becaufe defign always implies intelligence. There muft therefore be intelligence fomewhere. But may not this intelligence exift, not in the agent, but in the being who formed the agent? And may not the whole of the defign belong in reality to that being?

368 Nor material.

May not this agent, then, be material, and may not the whole of affimilation be performed by mere matter, acting according to laws given it by its maker? We anfwer, that what is called *matter*, or the fubftances enumerated in the firft part of CHEMISTRY (*Suppl.*) act always according to certain attractions and repulfions, which are known by the name of mechanical and chemical laws.

The phenomena of affimilation are fo far from being cafes of thefe laws, that they are abfolutely inconfiftent with them, and contrary to them; confequently the agent which prefides over *affimilation* is not *matter*. Concerning the nature of this fubftance it is not the bufinefs of this article to inquire; but as it poffeffes properties different from matter, and acts according to very different laws, it would be an abufe of terms to call it *matter*.

369 Animal principle.

We would give it the name of *mind*, were it not that metaphyficians have chofen to confider intelligence as the effence of mind; whereas this fubftance may be conceived to act, and really does act, without intelligence. There is no reafon, however, to fuppofe, with fome, that there are two fubftances in animals: one poffeffed of confcioufnefs as its effence, and therefore called *mind* or *foul* in man; another, deftitute of confcioufnefs, called the *living principle*, &c. employed in performing the different functions of affimilation, abforption, &c. It is much more reafonable to fuppofe, that in every animal and vegetable there is a peculiar fubftance, different from matter, to which their peculiar properties are owing; that this fubftance is different in every fpecies of animal and vegetable; that it is capable of acting according to certain fixed laws which have been impofed upon it by its Creator, and that thefe laws are of fuch a nature that it acts in fubfervience to a particular end; that this fubftance in plants is probably deftitute of intelligence; that in man and other animals it poffeffes intelligence to a certain extent, but that this intelligence is not effential to its exiftence nor to its activity; that it may be deprived of intelligence altogether, and afterwards recover it without altering its nature. Phyfiologifts have given it the name of *living principle*, becaufe its prefence conftitutes life. Perhaps it would be proper to diftinguifh that of animals by the name of *animal principle*. Upon what the intelligence of the animal principle depends, it is impoffible to fay; but it is evidently connected with the ftate of the brain. During a trance, or an apoplectic fit, it has often been loft for a time, and afterwards recovered.

370 Secretion.

17. Befides affimilation, the blood is alfo employed in forming all the different fecretions which are neceffary for the purpofes of the animal economy. Thefe have been enumerated in the laft chapter. The procefs is fimilar to that of affimilation, and undoubtedly the agents in both cafes are the fame; but we are

equally,

equally ignorant of the precife manner in which fecretion is performed as we are of affimilation.

371
Animals at length die, and why.

18. After thefe functions have gone on for a certain time, which is longer or fhorter according to the nature of the animal, the body gradually decays, at laft all its functions ceafe completely, and the animal dies. The caufe of this muft appear very extraordinary, when we confider the power which the animal has of renewing decayed parts; for it cannot be doubted that death proceeds, in moft cafes at leaft, from the body becoming incapable of performing its function. But if we confider that this power is limited, and that it muft ceafe altogether, when thefe parts of the fyftem begin to decay which are employed in preparing materials for future affimilation, our furprife will, in fome meafure, ceafe. It is in thefe parts, in the organs of digeftion and affimilation accordingly, that this decay ufually proves fatal. The decay in other parts deftroys life only when the wafte is fo rapid that it does not admit of repair.

What the reafon is that the decay of the organs caufes death, or, which is the fame thing, caufes the living principle either to ceafe to act, or to leave the body altogether, it is perfectly impoffible to fay, becaufe we know too little of the nature of the living principle, and of the manner in which it is connected with the body. The laft is evidently above the human underftanding, but many of the properties of the living principle have been difcovered: and were the facts already known properly arranged, and fuch general conclufions drawn from them as their connection with each other fully warrant, a degree of light would be thrown upon the animal economy which thofe, who have not attended to the fubject, are not aware of.

No fooner is the animal dead, than the chemical and mechanical agents, which were formerly fervants, ufurp the fupreme power, and foon decompofe and deftroy that very body which had been in a great meafure reared by their means. But the changes which take place upon animal bodies after death, are too important, and too intimately connected with the fubject of this article to be paffed over flightly. They fhall therefore form the fubject of the next chapter.

Chap. IV. Of the Decomposition of Animal Substances.

372
Decompofition of animal fubftances expofed to the air.

All the foft and the liquid parts of animals, when expofed to a moderate temperature of fixty-five degrees or more, pafs with more or lefs rapidity through the following changes. Their colour becomes paler, and their confiftence diminifhes; if it be a folid part, fuch as flefh, it foftens, and a ferous matter fweats out, whofe colour quickly changes; the texture of the part becomes relaxed, and its organization deftroyed; it acquires a faint difagreeable fmell: the fubftance gradually finks down, and is diminifhed in bulk; its fmell becomes ftronger and ammoniacal. If the fubject be contained in a clofe veffel, the progrefs of putrefaction, at this ftage, feems to flacken; no other fmell but that of a pungent alkali is perceived; the matter effervefces with acids, and converts fyrup of violets to a green. But if the communication with the air be admitted, the urinous exhalation is diffipated, and a peculiar putrid fmell is fpread around with a kind of impetuofity; a fmell of the moft infupportable kind, which lafts a long time, and pervades every place, affecting the bodies of living animals after the manner of a ferment, capable of altering the fluids: this fmell is corrected, and as it were confined by ammonia. When the latter is volatilized, the putrefactive procefs becomes active a fecond time, and the fubftance fuddenly fwells up, becomes filled with bubbles of air, and foon after fubfides again. Its colour changes, the fibrous texture of the flefh being then fcarcely diftinguifhable; and the whole is changed into a foft, brown, or greenifh matter, of the confiftence of a poultice, whofe fmell is faint, naufeous, and very active on the bodies of animals. The odorant principle gradually lofes its force; the fluid portion of the flefh affumes a kind of confiftence, its colour becomes deeper, and it is finally reduced into a friable matter, rather deliquefcent, which being rubbed between the fingers, breaks into a coarfe powder like earth. This is the laft ftate obferved in the putrefaction of animal fubftances; they do not arrive at this term but at the end of a confiderable time.†

† Fourc

373
Buried the eart

In carcafes buried in the earth, putrefaction takes place much more flowly; but it is fcarcely poffible to obferve its progrefs with accuracy. The abdomen is gradually dilated with elaftic fluids which make their appearance in it, and at laft it burfts and difcharges a horribly fetid and noxious gas; at the fame time a dark coloured liquid flows out. If the earth be very dry, and the heat confiderable, the moifture is often abforbed fo rapidly, that the carcafe, inftead of putrefying, dries, and is transformed into what is called a *mummy*.

374
When cumulat togethe

Such are the phenomena when dead bodies are left to putrefy feparately. But when great numbers of carcafes are crowded together in one place, and are fo abundant as to exclude the action of external air, and other foreign agents, their decompofition is entirely the confequence of the reciprocal action of their ingredients themfelves upon each other, and the refult is very different. The body is not entirely diffipated or converted into mould, but all the foft parts are found diminifhed remarkably in fize, and converted into a peculiar *faponaceous matter*. This fingular change was firft accurately obferved in the year 1786.

375
Conver into a f naceou matter.

The burial ground of the Innocents in Paris having become noxious to thofe who lived in its neighbourhood, on account of the difagreeable and hurtful odour which it exhaled, it was found neceffary to remove the carcafes to another place. It had been ufual to dig very large pits in that burial ground, and to fill them with the carcafes of the poorer fort of people, each in its proper bier; and when they were quite full, to cover them with about a foot depth of earth, and to dig another fimilar pit, and fill it in the fame manner. Each pit held between 1000 and 1500 dead bodies. It was in removing the bodies from thefe pits that this faponaceous fubftance was found. The grave-diggers had afcertained, by long experience, that about thirty years were required before all the bodies had undergone this change in its full extent.* Every part of the body acquired the properties of this fubftance. The inteftines and vifcera of the thorax had completely difappeared; but what is fingular enough, the brain had loft but little of its fize or appearance, though it was alfo converted into the fame fubftance.

* Fourc *Ann. d Chim.* 154.

37
Its pro ties.

This faponaceous matter was of a white colour, foft and unctuous to the touch, and melted, when heated, like mpo- cf A- Sub- ices. like tallow. It exhibited all the properties of a *soap*, containing, however, an excess of fatty matter. Fourcroy, who analysed it, found that it was composed of a fatty matter combined with ammonia, and that it contained also some phosphat of lime and ammonia. Diluted acids decomposed it, and separated the fatty matter; alkalies and lime, on the other hand, drove off the ammonia. When exposed to the air, it gradually lost its white colour; the ammonia, in a great measure, evaporated, and what remained had something of the appearance of wax. It absorbed water with great avidity, and did not part with it readily. Its white colour was owing to the presence of that liquid. The oily matter, when separated by means of a diluted acid, was concrete, and of a white colour, owing to the mixture of a quantity of water. When dried, it acquires a greyish brown colour, a lamellar and crystalline texture, like that of spermaceti; but if it has been rapidly dried it assumes the appearance of wax. It melts, when heated, to 126°; when properly purified, by passing it through a linen cloth while fluid, it has scarcely any smell. Alcohol does not act upon it while cold, but at the temperature of 120° it dissolves it: when the solution cools, the fatty matter precipitates, and forms a gritty mass. With alkalies it forms a soap; and when set on fire it burns precisely like oil or fat, only that it exhales a more unpleasant odour.†

† ...rcoy, ...de ... viii.

77 ...iced ...run- ...wa-

Mr Smith Gibbes found the same substance in the pit into which animal matters are thrown at Oxford after dissection. A small stream of water constantly passes through this pit; a circumstance which induced him to try whether animal muscle exposed to the action of a running stream underwent the same change. The experiment succeeded completely: he attempted, in consequence, to render this substance, to which he gave the name of *spermaceti*, useful in those manufactures which required tallow; but the fetid odour which it constantly exhales was an insurmountable objection. Attempts were indeed made to get over it; but as we do not hear that Mr Smith Gibbes's spermaceti has been introduced into any manufacture, we have reason to conclude that none of these attempts succeeded.‡

Decomposition of Animal Substances.

‡ *Phil. Transf.* 1794 and 1795.

378 Theory of putrefaction imperfect.

Such are the phenomena of putrefaction, as far as they are at present known to chemists. Any attempt to explain the manner in which these changes take place, would be exceedingly imperfect indeed; not only because we are ignorant of the strength of the affinities of the different elementary parts of animal bodies for each other, but because we do not even know the manner in which these elements are combined, and consequently we cannot know by what particular forces these compounds are destroyed. We know only that a certain degree of heat, and the presence of moisture, are in all cases necessary for the putrefactive process; for animal bodies may be kept almost any length of time, without decomposition, at the freezing temperature; and when dried quickly, and kept in that state, they undergo no farther change.

PART III. OF DYEING.

MANKIND have in all periods of society manifested a fondness for beautiful and gaudy colours. Naked savages at first applied them to their skin. This was the case with the Britons, and with the Gauls, too, in the time of Cæsar; it is even still the practice in the South Sea islands, and many parts of America. When mankind had advanced so far towards civilization as to wear garments, they naturally transferred to them the colours which they admired. Hence the origin of *dyeing*; which is of such antiquity, that it precedes the earliest records left us by profane authors. We see from the book of Genesis the great progress which it had made in the time of the patriarchs.

9 ...1 of ...g.

Dyeing seems to have originated in India, and to have spread gradually from that country to the west. The Indians were the inventors of the method of dyeing cotton and linen, which was not understood in Europe before the conquests of Alexander the Great. The Phenicians excelled in the art at a very early period. It was from them that the Jews purchased all the dyed stuffs described in Exodus. The Phenician dyers seem to have confined their art to wool: silk was unknown to them, and linen was usually worn white. From them the art of dyeing passed to the Greeks and Romans.

During the fifth century, the Western Empire was overturned by the northern nations, and with it the arts and sciences, which had flourished under the protection of the Romans, disappeared. A few of the arts, indeed, were preserved in Italy, but they were obscured and degraded. By degrees, however, a spirit of industry began to revive in that country. Florence, Genoa, and Venice, becoming rich commercial cities, carried on a considerable intercourse with the Grecian empire, where many of the arts had been preserved. This intercourse was much increased by the crusades. The Italian cities became rich and powerful: the arts which distinguish civilized nations were cultivated with emulation, and dyeing, among others, was rapidly improved.

380 Its progress in modern Europe.

In the year 1429, the first treatise on dyeing made its appearance at Venice, under the name of *Moriegola dell'arte de tentori*. Giovanne Ventura Rosetta collected, with great industry, all the processes employed by the dyers of his time, and published them in 1548, under the title of *Plictho*.* For many years dyeing was almost exclusively confined to Italy; but it gradually made its way to France, the Low Countries, and to Britain. The minister Colbert, who employed his talents in extending the commerce and manufactures of France, paid particular attention to the art of *dyeing*. In the year 1672, he published a table of instructions, by which those who practised the art were laid under several very improper restrictions. But the bad effects of these were in a good measure obviated by the judicious appointment of men of science to superintend the art. This plan, begun by Colbert, was continued by the French government. Accordingly, Dufay, Hellot, Macquer, and Berthollet, successively filled the office. It is to this establishment, and to exertions of the celebrated chemists who have filled it, that France is indebted for the improvements she has made in the art of dyeing during the course of the 18th century. Under the direction of Dufay, a new table of regulations was published in 1737, which superseded that of Colbert. Hellot,

* *Berthollet on Dyeing*, i. 22.

Hellot, his successor, published, in 1740, an excellent system of dyeing wool; and Macquer in 1763 published his treatise on dyeing silk.

In Britain, though dyeing has been carried on for many years with great success, very little progress was made in investigating the theory of the art. The Royal Society, indeed, soon after its institution, recommended it to some of its members; but as no treatise made its appearance in consequence of this, it seems very soon to have lost their attention. Lewis, many years after, published some very important remarks on dyeing; but they were confined to a few processes. The British dyers satisfied themselves with a translation of Hellot. Such was the state of the art when the article DYEING in the *Encyclopædia* was drawn up. It consists chiefly of an abstract of Hellot's treatise. But within the last 30 years, the attention of men of science has been very much turned to this complicated art. In Sweden has appeared the treatise of Scheffer, and Bergman's notes on it; in Germany, the experiments of Beckmann, Poerner, and Vogler, and the dissertation of Francheville: in France, the treatises of D'Ambournay, D'Apligny, Hauſsmann, Chaptal, and, above all, of Berthollet; in this country, the ingenious remarks of Delaval, of Henry, and the valuable treatise of Dr Bancroft; besides many other important essays. These, together with the progress of the science of chemistry, on which the theory of dyeing depends, have thrown so much new light upon the art, that we find ourselves under the necessity of tracing the whole over again. We shall pass over, however, very slightly those parts of the art which have been sufficiently explained in the article DYEING, *Encycl.*

To understand the art of *dyeing*, we must be acquainted with the *substances* on which it is practised, with the nature of *colour*, and with the method of permanently changing the colour of bodies. These three things we shall consider in the three following chapters. In the first, we shall give an account of the substances of which garments are usually made, with which alone the art of dyeing is concerned; in the second, we shall inquire into the nature of colour; and in the third, explain the theory of dyeing, as far as it is at present understood. In some subsequent chapters, we shall give a general view of the processes by which the different colours are given to stuffs.

CHAP. I. OF THE SUBSTANCES USED FOR CLOTHING.

381 Cloathing. THE substances commonly employed for clothing may be reduced to four; namely *wool, silk, cotton, linen*. As there is no name in the English language which includes all these substances, we shall take the liberty, in the remainder of this article, to use the word *cloth* for that purpose. They are all made into *cloth*, of some kind or other, before they can be useful as articles of *clothing*.

382 Consists of wool, 1. WOOL, as is well known, is the hair which covers the bodies of sheep; it differs from common *hair* merely in fineness and softness. It filaments possess a considerable degree of elasticity; they may be drawn out beyond their usual length, and afterwards recover their form when the external force is removed. The surface of wool and hair is by no means smooth: No inequality, indeed, can be perceived by a microscope; nor is any resistance felt when a hair is laid hold of in one hand, and drawn between the fingers of the other, from the *root* towards the *point*; but if it be drawn from the *point* towards the *root*, a resistance is felt which did not take place before, a tremulous motion is perceived, and a noise may be distinguished by the ear. If, after laying hold of a hair between the thumb and fore finger, we rub them against each other in the longitudinal direction of the hair, it acquires a progressive motion *towards the root*; the *point* gradually approaches the fingers, while the *root* recedes from them; so that the whole hair very soon passes through between the fingers.

These observations, first made by Mr Monge, demonstrate that the surface of hair and wool is composed, either of small laminæ, placed over each other in a slanting direction from the root towards the point, like the scales of a fish—or of zones, placed one above another, as takes place in the horns of animals.*

* *Ann. de Chim.* vi. 300.

On this structure of the filaments of hair and wool depend the effects of *felting* and *fulling*. In both of these operations, the filaments are made, by an external force, to rub against each other; the position of their asperities prevents them from moving, except in one direction: they are mutually entangled, and obliged to approach nearer each other. Hence the thickness which cloth acquires in the fulling mill. The filaments have undergone a certain degree of felting, and are interwoven like the fibres of a hat. The cloth is contracted both in length and breadth: it may be cut without being subject to ravel; nor is there any necessity for hemming the different pieces employed to make a garment. See FELTING and FULLING, in this *Suppl.*

Wool is naturally covered with a kind of grease, which preserves it from moths. This is always removed before the wool is dyed; because its presence is very prejudicial to the success of that operation. The asperities of the surface of woolly fibres would impede the converting of it into thread by spinning; but they are in a great measure covered, previous to that operation, by soaking the wool with oil. The oil must also be removed before the wool be dyed. This process is called SCOURING, which see in this *Suppl.*

We have already, in the second part of this article, given an account of what is at present known concerning the composition of wool and hair. It would be foreign to the subject of this chapter, to describe the method of *spinning* and *weaving* wool.

Wool is of different colours; but that which is white is preferred for making cloth; because it answers better for the purposes of dyeing than any other kind.

2. SILK is a substance spun in fine threads by the *silk worm*. Its fibres are not scaly like those of wool; neither have they the same elasticity: but silk, in its natural state, before it has undergone any preparation, has a considerable degree of stiffness and elasticity. In this state it is known by the name of *raw silk*. It is covered with a kind of gummy varnish, which may be removed by scouring with soap. The scouring deprives it of its stiffness and elasticity. Raw silk is of a yellow colour, owing to yellow resinous matter with which it is naturally combined. We have given the method of separating this matter, and also the gum, in the article BLEACHING, *Supplement.* 383 Silk.

Silk, before it is dyed, is always freed from its gum, and generally also from its resin. It may be dyed without ſtances ...d for ...thing.

out the application of heat; which is not the caſe with wool.

3. Cotton is a fine downy ſubſtance, contained in
384 the pods of different ſpecies of goſſypium. The ſpecies from which the greater part of the cotton brought to Britain is taken is the *herbaceum*. The quantity imported annually into Britain is very great; in 1786 it amounted to 20 millions of pounds.‡ Cotton varies greatly, according to the plant on which it grows, and the climate where it is cultivated. The chief differences are in colour, and in the length, fineneſs, and ſtrength of the filaments.

No aſperities can be diſcovered on the ſurface of theſe filaments; but Lewenhoeck obſerved, by means of a microſcope, that they are triangular, and have three ſharp edges. This is probably the reaſon of a well known fact, that cotton cloth, when applied by way of dreſſing, always irritates a ſore.

Some cottons are naturally white; others a fine light yellow, as thoſe of which nankeen is made; but moſt commonly cotton is of a dirty browniſh yellow colour, which muſt be removed before the ſtuff can be dyed. This is done by the proceſs of *bleaching*. The fibres of cotton, even after being bleached, retain almoſt always ſome lime and oxyd of iron, which muſt be removed before we attempt to dye the cotton; becauſe their preſence would ſpoil the colour. This is done by ſteeping the cotton for ſome time in water acidulated with ſulphuric acid.

Cotton, like ſilk, may be dyed without the aſſiſtance of heat. It is not nearly ſo eaſy to dye cotton any particular colour as it is to dye wool or ſilk. If wool and cotton be put into the ſame dyeing veſſel, the wool frequently acquires the wiſhed-for colour before the
385 cotton has loſt any of its original whiteneſs.

4. Lint, from which *linen* is made, is the inner bark of the *linum uſitatiſſimum*, or *flax*; a plant too well known in this country to require any deſcription.

The flax, when ripe, is pulled and ſteeped for ſome days in water, in order to ſeparate the green coloured glutinous matter which adheres to the inner bark. This matter undergoes a degree of putrefaction; carbonic acid gas and hydrogen gas, are diſengaged:* it is decompoſed, and carried off by the water. If the water, in which the flax is ſteeped, be completely ſtagnant, the putrefaction is apt to go too far, and to injure the fibres of the lint; but in a running ſtream, it does not go far enough, ſo that the green matter ſtill continues to adhere to the lint. Flax, therefore, ſhould be ſteeped in water neither completely ſtagnant, nor flowing too freely, like a running ſtream.

The flax is afterwards ſpread upon the graſs, and expoſed for ſome time to the air and ſun: this improves the colour of the lint, and renders the woody part ſo brittle, that it is eaſily ſeparated by the action of the lint mill. The ſubſequent operations, of *dreſſing*, *ſpinning*, *weaving*, and *bleaching*, do not belong to this article.

The fibres of lint have very little elaſticity. They appear to be quite ſmooth; for no aſperities can be perceived by the microſcope, nor detected by the feel; nor does linen irritate ſores, as is the caſe with cotton.

Linen may be dyed without the aſſiſtance of heat; but it is more difficult to give it permanent colours than even cotton.

Thus we have given a ſhort deſcription of wool, ſilk, cotton, and linen. The firſt two are animal ſubſtances; the two laſt vegetable. The animal contain much azot and hydrogen; the vegetable much carbon: The animal are readily deſtroyed by acids and alkalies; the vegetable withſtand the action of theſe ſubſtances better; even nitric acid does not readily deſtroy the texture of cotton. The animal ſubſtances are more eaſily dyed than the vegetable, and the colours which they receive are more permanent than thoſe given to cotton and linen by the ſame proceſſes.

Such are the properties of the cloths on which the art of dyeing is exerciſed. But what is the nature of theſe *colours* which it is the object of that art to communicate? We ſhall examine this ſubject in the following chapter.

Colours.

Chap. II. Of Colours.

All viſible objects, as has been long ago ſufficiently eſtabliſhed, are ſeen by means of rays of light paſſing off from them in all directions, and partly entering the eye of the ſpectator.

1. For the theory of light and viſion we are indebted to Sir Iſaac Newton. He firſt demonſtrated, that light is compoſed of ſeven rays, differing from each other in refrangibility, and other properties. Each of theſe rays is diſtinguiſhed by its particular colour. Hence their names, red, orange, yellow, green, blue, indigo, violet. By mixing together theſe different rays, in various proportions, all the colours known may be obtained. Thus red and yellow conſtitute orange; yellow and blue conſtitute green; blue and red conſtitute purple, violet, aurora, &c. according to their proportions. When all the rays are mixed together, they form a white. 386 Colour produced by light.

2. Bodies differ very much from each other in their power of reflecting light. Some reflect it in vaſt quantity, as metals; others reflect but little, as charcoal. In general, the ſmoother the ſurface of a body is, the greater is the quantity of light which it reflects. Hence the effect of poliſhing in increaſing the brightneſs of bodies. But it is not in the quantity of the light reflected alone that bodies differ from each other; they differ alſo in the quality of the light which they reflect. Some bodies reflect one or more particular ſpecies of ray to the excluſion of the reſt. This is the reaſon that they appear to us of different colours. Thoſe bodies which reflect only red rays are red; thoſe that reflect yellow rays are yellow; thoſe that reflect all the rays equally are white; thoſe that reflect too little to affect the eye are black. It is to the different combinations of rays reflected from the ſurface of bodies that all the different ſhades of colour are owing. 387 Bodies reflect different rays.

Colour, then, in *opaque* bodies, is owing to their diſpoſition to *reflect* certain rays of light, and to *abſorb* the reſt; in *tranſparent* bodies, to their diſpoſition to *tranſmit* certain rays, and to *abſorb* the others. But this ſubject has been diſcuſſed, at ſufficient length, in the article Optics, *Encycl.*; to which, therefore, we beg leave to refer the reader. Here we mean only to inquire into the *cauſe* of this diſpoſition of the particles of bodies. 388 Hence their different colours.

3. Sir Iſaac Newton, to whom we are indebted for the exiſtence of optics as a ſcience, made a ſet of experiments to aſcertain the changes of colour which thin plates of matter aſſume in conſequence of an increaſe or dimi- 389 Newtonian theory to explain this difference

Colours. diminution of their thickneſs. Theſe experiments were of a very delicate nature; but Newton conducted them with ſo much addreſs, and varied and repeated them with ſo much induſtry, that he was enabled to render them ſurpriſingly accurate.

Upon a large double convex lens of a 50 feet focus, he placed the plane ſurface of a planoconvex lens, and preſſed the lenſes ſlowly together. A circle, of a particular colour, appeared in the centre, where the two glaſſes touched each other. This circle gradually increaſed in diameter as the preſſure was augmented; and at laſt a new circle, of another colour, occupied the centre, while the firſt colour aſſumed the form of a circular ring. By increaſing the preſſure, a new coloured circle appeared in the centre, and the diameter of the other two increaſed. In this manner he proceeded, till he produced no leſs than 25 different coloured circular rings. Theſe he divided into ſeven orders, on account of the repetition of the ſame colour. They were as follows, reckoning from the central colour, which was always black.*

* *Newton's Optics*, 191. Clarke's edition.

1. Black, blue, white, yellow, red.
2. Violet, blue, green, yellow, red.
3. Purple, blue, green, yellow, red.
4. Green, red.
5. Greeniſh blue, red.
6. Greeniſh blue, pale red.
7. Greeniſh blue, reddiſh white.

Theſe different colours were occaſioned by the thin film of air between the two glaſſes. Now this film varies in thickneſs from the centre of the lens towards the circumference; that part of it which cauſes the black colour is thinneſt, and the other coloured circles are occaſioned by air gradually increaſing in thickneſs. Newton meaſured the *relative thickneſs* of the air which produced each of theſe coloured circles; and he found it as follows:†

† *Ibid.* p. 215.

1.	Black	1		green	$25\frac{1}{5}$
	blue	$2\frac{2}{5}$		yellow	$27\frac{1}{7}$
	white	$5\frac{1}{4}$		red	31
	yellow	$7\frac{1}{9}$	4.	Green	35
	red	$8\frac{1}{2}$		red	$40\frac{1}{3}$
2.	Violet	$11\frac{1}{6}$	5.	Gr. blue	46
	blue	14		red	$52\frac{1}{2}$
	green	$15\frac{1}{8}$	6.	Gr. blue	$58\frac{3}{4}$
	yellow	$16\frac{2}{7}$		red	65
	red	$18\frac{1}{3}$	7.	Gr. blue	71
3.	Purple	21		reddiſh white	77
	blue	$23\frac{2}{5}$			

The *abſolute* thickneſs of theſe films cannot be aſcertained, unleſs the diſtance between the two glaſſes, at that part where the black ſpot appears, were known. Now there is no method of meaſuring this diſtance; but it certainly is not greater than the thouſandth part of an inch.

He repeated theſe experiments with films of water, and even of glaſs, inſtead of air; and he found, that in theſe caſes the thickneſs of the films, reflecting any particular colour, was diminiſhed, and that this diminution was proportional to the denſity of the reflecting film.

Colours. From theſe experiments Sir Iſaac Newton concluded, that the diſpoſition of the particles of bodies to reflect or tranſmit particular rays depended upon their ſize and their denſity: and he even attempted to aſcertain the ſize, or at leaſt the thickneſs, of the particles of bodies from their colours. Thus a particle of matter, whoſe denſity is the ſame with that of glaſs which reflects a green of the third order, is of the thickneſs of $\frac{16\frac{1}{4}}{1000000}$ of an inch.*

* *Newton's Optics*, 2[illegible]

In the year 1765, Mr Delaval publiſhed, in the Philoſophical Tranſactions, a very ingenious paper on the ſame ſubject. In this paper, he endeavours to prove, by experiment, that the colours of metallic bodies depend upon their denſity. He takes it for granted, at the ſame time, that the ſize of the particles of bodies is inverſely as the denſity of bodies. The denſeſt bodies, according to him, are red; the next in denſity, orange; the next, yellow; and ſo on, in the order of the refrangibility of the different rays. Some time after, the ſame ingenious gentleman, in his *Experimental Inquiry into the Cauſe of the Permanent Colours of Opaque Bodies*, extended his views to animal and vegetable ſubſtances, and endeavoured to prove the truth of Newton's theory by a very great number of experiments.

Such is a view of the opinion of Newton and Delaval reſpecting the cauſe of bodies reflecting or tranſmitting particular rays of light, as far at leaſt, as that theory relates to colour. They aſcribed this cauſe *ſolely* to the *ſize* and the *denſity* of the particles of bodies.

By *particles*, it is evident that nothing elſe can be meant than the *integrant particles* of bodies. Newton, indeed, does not expreſs himſelf preciſely in this language; but it is plain that nothing elſe could be his meaning. Mr Delaval undoubtedly is of that opinion.

According to the Newtonian theory of colour, then, it depends ſolely upon the *ſize* of the integrant particles of bodies whoſe denſity is the ſame; and upon the *ſize* and the *denſity* jointly of all bodies (T).

390 Examined.

It is evident that the truth of the Newtonian theory muſt depend upon its coincidence with what actually takes place in nature, and that therefore it can only be determined by experiment. Newton himſelf produced but very few experiments in ſupport of it; and though this deficiency was amply ſupplied by Mr Delaval, it is needleſs for us to adduce any of theſe here; becauſe, from the prodigious accumulation of chemical facts ſince theſe experiments were made, the very baſis upon which they ſtood has been deſtroyed, and conſequently all the evidence reſulting from them has been annihilated. They proceeded on the ſuppoſition, that acids render the particles of bodies *ſmaller*, and alkalies *larger* than they were before, without producing any other change whatever in the bodies on which they act. To attempt a refutation of this opinion at preſent would be unneceſſary, as it is well known not to be true.

Let us therefore compare the Newtonian theory of colour with thoſe chemical changes which we know for certain to alter the ſize of the particles of bodies, in order to ſee whether they coincide with it. If the theory be true, the two following conſequences muſt hold

(T) Newton, however, pointed out an exception to this law, concerning which Mr Delaval has been more explicit. Combuſtible bodies do not follow that law, but ſome other. Mr Delaval has ſuppoſed, that this deviation is owing to the preſence of phlogiſton.

hold in all caſes: 1. Every alteration in the ſize of the integrant particles of bodies muſt cauſe theſe particles to aſſume a different colour. 2. Every ſuch alteration muſt correſpond preciſely with the theory; that is to ſay, the new colour muſt be the very colour, and no other, which the theory makes to reſult from an increaſe or diminution of ſize.

391 found ctive.

Now neither of theſe conſequences holds in fact. We have no method indeed of aſcertaining the ſizes of the integrant particles of bodies, nor of meaſuring the preciſe degree of augmentation or diminution which they ſuffer; but we can in many caſes aſcertain, whether any new matter has been added to a particle, or any matter abſtracted from it; and conſequently whether it has been augmented or diminiſhed; which is ſufficient for our preſent purpoſe.

For inſtance, whatever be the ſize of an integrant particle of gold, it cannot be denied that an integrant particle of oxyd of gold is greater; becauſe it contains an integrant particle of gold combined with at leaſt one integrant particle of oxygen. Now the colour both of gold and of its oxyd is yellow, which ought not to be the caſe, according to the Newtonian theory. In like manner, the amalgam of ſilver is white, preciſely the colour of ſilver and of mercury; yet an integrant particle of the amalgam muſt be larger than an integrant particle either of ſilver or of mercury. Many other inſtances beſides theſe will occur to every one, of changes in the ſize of the particles taking place without any change of colour. All theſe are incompatible with the Newtonian theory.

It may be ſaid, perhaps, in anſwer to this objection, that there are different orders of colours; that the ſame colour is reflected by particles of different ſizes; and that the increaſed particles, in the inſtances above alluded to, retain their former colour, becauſe the increment has been preciſely ſuch as to enable them to reflect the ſame colour in the next higher order.

This very anſwer is a complete proof that the Newtonian theory is not ſufficient to account for the colours of bodies; for if particles of *different* ſizes reflect the ſame colour, *ſize* certainly is not the only cauſe of this reflection.* There muſt be ſome other cauſe very different from ſize. Nor is this all; the moſt common colour which remains after an increaſe of the ſize of the integrant particles of bodies is white; yet white does not appear in any of the orders except the firſt, and therefore its permanence cannot be accounted for by any ſuppoſition compatible with the Newtonian theory.

ncreaſt rma- Colours,

Even when alterations in the colour of bodies accompany the increaſe or diminution of the ſize of their particles, theſe alterations ſeldom or never follow an order which correſponds with the theory. As for metals, it is ſelf-evident that their colour does not depend upon their denſity. Platinum is the denſeſt body known, and yet it is not red, as it ought to be, but white like tin; a metal which has little more than one third of the denſity of platinum.

The green oxyd of iron, when combined with pruſſic acid, becomes white; yet the ſize of its particles muſt be increaſed. Now this change of colour is incompatible with the theory; for according to it, every change from green to white ought to be accompanied by a diminution inſtead of an increaſe of ſize. A particle of indigo, which is naturally green, becomes blue by the addition of oxygen, which muſt increaſe its ſize. This change is alſo incompatible with the theory. But it is unneceſſary to accumulate inſtances, as they will naturally occur in ſufficient number to every one.

It follows irreſiſtibly from theſe facts, that the Newtonian theory is not ſufficient to explain the *cauſe* of colour; or what cauſes bodies to reflect or tranſmit certain rays, and to abſorb the reſt.

4. We have endeavoured, in the article CHEMISTRY, *Suppl.* to ſhew, that bodies have a particular affinity for the rays of light; and that the phenomena of light depend entirely upon theſe affinities. Indeed this conſequence follows from the properties of light eſtabliſhed by Newton himſelf. We ſhall not repeat here the proofs upon which the exiſtence of theſe affinities is founded: the reader may eaſily ſatisfy himſelf by conſulting the article above referred to. 392 Bodies owe their colour to their affinity for light.

Every coloured body, then, has a certain *affinity for* ſome of the rays of light. Thoſe rays for which it has a ſtrong affinity are abſorbed by it and retained, and the other rays for which it has no affinity are either reflected to tranſmitted, according to the nature of the body and the direction of the incident ray. Thus a red body has an affinity for all the rays except the red; it abſorbs therefore the other ſix, and reflects only the red: a green body abſorbs all but the green rays, or perhaps the red and yellow: a black body has a ſtrong affinity for all the rays, and therefore abſorbs them all: while a white body, having no ſtrong affinity for any of the rays, reflects or tranſmits them all.

If affinity, as we have endeavoured to ſhew in the article CHEMISTRY, *Suppl.* be an attraction of the ſame nature with gravitation, and increaſing as the diſtance diminiſhes, it muſt depend upon the nature of the attracting particles. Now the only differences which we can conceive to exiſt between the particles of bodies, are differences in *ſize*, in *denſity*, and in *figure*. Changes in theſe three things will account for all the varieties of affinity. Now if affinity depends upon theſe three things, and if colour depends upon the affinity between the particles of bodies and the different rays of light as cannot be denied, it is clear that the cauſe of the colour of bodies may be ultimately reſolved into the ſize, denſity, and figure, of their particles. Newton's theory, then, was defective, becauſe he omitted the *figure* of the particles, and aſcribed the whole to variations in *ſize* and *denſity*.

When we ſay, then, that colour is owing to *affinity*, we do not contradict the opinion of Newton, as ſome philoſophers have ſuppoſed, but merely extend it: Newton was *not miſtaken* in ſaying, that colour depends upon the ſize and the denſity of the particles of bodies; his miſtake lay in ſuppoſing that it depends upon theſe *alone*.

5. Since the colour of bodies depends upon their affinity for light, and ſince every body has a certain colour, becauſe it abſorbs and retains particular rays while it tranſmits or reflects the reſt, it is evident that every body muſt continue of its firſt colour till one of two things happen; either till it be ſaturated with the rays which it abſorbs, and of courſe ceaſe to abſorb any more, or till its particles change their nature, by being either decompoſed or combined with ſome new ſubſtance. We have no poſitive proof that the firſt 393 Why bodies change their colour.

cauſe

Colours.

caufe of change ever occurs, as many fubftances have been expofed to the action of light for a very long time without any change of colour. The abforbed light feems to make its efcape, either in its own form, or in fome unknown or unfufpected one. The fecond caufe of change is very common: indeed its action may be detected in almoft every cafe of alteration in the colour of bodies. The green oxyd of iron, by combining with oxygen, becomes red; and this red oxyd, when combined with pruffic acid, affumes a blue colour, and with gallic acid a black colour. The caufe of this change of colour, when the compofition of a body changes, is obvious: every change of compofition muft alter the affinity, becaufe it muft of neceffity produce changes in the fize, denfity, or figure of the particles, or perhaps in all of thefe. Now if the affinity of a body for other bodies be altered, it is natural to fuppofe that it will be altered alfo for light. Accordingly this happens in moft inftances. It does not, however, take place conftantly, for very obvious reafons. It may happen that the new denfity, fize or figure of the altered body is fuch, as to render it ftill proper for attracting the very fame rays of light which it formerly attracted. Juft as iron, after being combined with a certain dofe of oxygen, is converted into green oxyd, which ftill retains an affinity for oxygen.

It is evident from all this, that in moft cafes the permanence of colour in bodies will depend upon the permanence of their compofition, or on the degree of facility with which they are acted upon by thofe bodies, to the agency of which they are expofed.

394 Permanency of colour of great importance in *dyeing*.

In *dyeing*, the permanence of colour is of very great importance. Of what value is the beauty of a colour, provided that colour be fugitive or liable to change into fome other. In all cafes, therefore, it is of confequence to attend to the fubftances to which dyed cloth is expofed, and to afcertain their action upon every particular dyeing ingredient. Now the bodies to which dyed cloth is almoft conftantly expofed are *air* and *light*; the combined action of which has fo much influence, that very few dyes can refift it.

395 How dyes lofe their colour.

It is evident that thofe fubftances which have a ftrong affinity for oxygen cannot retain their colour, provided they be able to take it from atmofpheric air. Thus the green colour of green oxyd of iron and of indigo is not permanent, becaufe thefe fubftances readily abforb oxygen from air. In order, then, that a colour can have any permanence, the coloured body muft not have fo great an affinity for oxygen as to be able to take it from air. Thofe bodies have in general the moft permanent colours which are already faturated with oxygen, and therefore not liable to abforb more. Such is the cafe with red oxyd of iron.

All coloured bodies are compounds; fome of thofe only excepted which ftill retain an affinity for oxygen. Coloured bodies, therefore, are compofed of feveral ingredients; and in every coloured body, at leaft *fome* of the ingredients have a ftrong affinity for oxygen. Now, before the colour of a body can be permanent, its ingredients muft be combined together by fo ftrong affinities, that oxygen gas is unable to decompofe it by combining with one or more of its ingredients and carrying it off. If this decompofition take place at once, it is impoffible for the colour of a body to have any permanence. If it takes place flowly, the colour of the body gradually decays. The action of oxygen gas upon bodies is much increafed in particular circumftances. Almoft all coloured bodies are decompofed by oxygen gas by the affiftance of heat. Thus if wheat flour be expofed to the heat of 448°, it lofes its white colour, and becomes firft brown and then black. At this temperature it is decompofed, and a part, or even the whole of its hydrogen, combining with oxygen, flies off. Cloth is fcarcely ever expofed to fo high a temperature; but there are other circumftances in which it may be placed which may have a fimilar effect. Thus the action of light feems in fome fubftances to be fimilar to that of heat, and to facilitate the decompofition of the coloured matter by the combination of fome of its ingredients with oxygen.*

Coloured bodies, in order to have permanent colours, muft not be liable to be decompofed by other fubftances more than by oxygen. For inftance, if they contain oxygen and hydrogen, thefe two bodies muft not be liable to combine together and form water, nor muft oxygen and carbon be liable to combine and form carbonic acid gas. Light feems to have a tendency to decompofe many bodies in this manner, and even to carry off oxygen from them in the form of oxygen gas. Thus it renders the nitrat of filver black by carrying off part of its oxygen, and it reduces oxy-muriatic acid to common muriatic acid by the fame means.

* Berth. on Dye. i. 45.

Thefe are the caufes which induce a change in the colour of coloured bodies, as far as they have been traced; namely, the addition of oxygen, the abftraction of oxygen, partial decompofition by fome one of their ingredients combining with oxygen, complete or partial decompofition by the ingredients entering into new combinations with each other. The coloured matters ufed in dyeing are very liable to thefe changes, becaufe they are in general animal or vegetable fubftances of a very compound nature. Of courfe their ingredients have often no very ftrong affinity for each other, and therefore are very liable to decompofition; and every one of the ingredients has in general a very ftrong affinity for oxygen. This renders the choice of proper colouring matters for dyeing a very important point. In order to have permanency, they muft not be liable to the above changes, not to mention their being able alfo to withftand the action of foap, acids, alkalies, and every other fubftance to which dyed cloth may be expofed.

3[illegible] Meth[od of] afcert[ain]ing th[e perma]nence [of] dyes.

It becomes therefore a point of fome confequence to be able to afcertain whether cloth dyed of any particular colour be permanently dyed or not. The proper method of afcertaining this is by actually expofing fuch cloth to the fun and air; becaufe as thefe are the agents to which it is to be expofed, and which have the moft powerful action, it is clear, that if it withftand them, the colour muft be confidered as permanent. But this is a tedious procefs. Berthollet propofed expofing fuch cloth to the action of oxy-muriatic acid; thofe colours that withftand it being confidered as permanent. This method anfwers in many cafes: but it is not always to be depended on; for it deftroys fome permanent colours very fpeedily, and does not alter others which are very fading.* But we fhall have occafion to refume this fubject afterwards.

* Ban[croft,] i. 49.

3[illegible] Divifi[on of] colour[s].

Dyers divide colours into two claffes; namely, *fimple* and *compound*. The fimple colours are thofe which cannot

...ing in General. cannot be produced by the mixture of other colours. They are in number four.

1. Blue, 3. Red,
2. Yellow, 4. Black.

Some add a fifth, *brown*; but it may be produced by combining two others.

The compound colours are thoſe which are produced by mixing together any two ſimple colours in various proportions. They conſtitute all the colours except the four ſimple and their various ſhades.

Thus we have examined the nature of colours; but we have ſtill to explain the method of giving permanent colours to cloth. This ſhall be the ſubject of the next chapter.

CHAP. III. OF DYEING IN GENERAL.

FROM the theory of colour laid down in the laſt chapter, it follows, that permanent alterations in the colour of cloth can only be induced two ways; either by producing a chemical change in the cloth, or by covering its fibres with ſome ſubſtance which poſſeſſes the wiſhed-for colour. Recourſe can ſeldom or never be had to the firſt method, becauſe it is hardly poſſible to produce a chemical change in the fibres of cloth without ſpoiling its texture and rendering it uſeleſs. The dyer, therefore, when he wiſhes to give a new colour to cloth, has always recourſe to the ſecond method.

98 ...tuffs 1. The ſubſtances employed for this purpoſe are called *colouring matters*, or *dye ſtuffs*. They are for the moſt part extracted from *animal and vegetable ſubſtances*, and have uſually the colour which they are intended to give to the cloth. Thus a blue colour is given to cloth by covering its fibres with indigo, a blue powder extracted from a ſhrub; a red colour, by the colouring matter extracted by water from an inſect called *cochineal*, or from the root of a plant called *madder*.

99 ...t re-...ight. 2. Mr Delaval has publiſhed a very intereſting ſet of experiments on colouring matters in the ſecond volume of the Mancheſter Memoirs. He has proved, by a very numerous ſet of experiments, that they are all tranſparent, and that they do not *reflect* any light, but only tranſmit it: For every colouring matter which he tried, even when diſſolved in a liquid, and forming a tranſparent coloured ſolution, when ſeen merely by reflected light, was black, whatever was the colour of the matter; but when ſeen by tranſmitted light, it appeared of its natural colour.* This diſcovery, which Mr Delaval has eſtabliſhed very completely, and to which, as far at leaſt as dye ſtuffs are concerned, there are but few exceptions, is of very great importance to the art of dyeing, and explains ſeveral particulars which would otherwiſe be unintelligible.

...nch. ii.

Since the particles of the colouring matter with which cloth, when dyed, is covered, are tranſparent, it follows, that all the light reflected from dyed cloth muſt be reflected, not by the dye ſtuff itſelf, but by the fibres of the cloth below the dye ſtuff. The colour therefore does not depend upon the dye alone, but alſo upon the previous colour of the cloth. If the cloth be *black*, it is clear that we cannot dye it any colour whatever; becauſe as no light in that caſe is reflected, none can be tranſmitted, whatever dye ſtuff we employ. If the cloth were red, or blue, or yellow, we could not dye it any colour except black; becauſe as only red, or blue, or yellow rays were reflected, no other could be tranſmitted (x). Hence the importance of a fine white colour when cloth is to receive bright dyes: It then reflects all the rays in abundance; and therefore any colour may be given, by covering it with a dye ſtuff which tranſmits only ſome particular rays. Dyeing in General.

3. If the colouring matters were merely ſpread over the ſurface of the fibre of cloth by the dyer, the colours produced might be very bright, but they could not be permanent; becauſe the colouring matter would be very ſoon rubbed off, and would totally diſappear whenever the cloth was waſhed, or even barely expoſed to the weather. The colouring matter, then, however perfect a colour it poſſeſſes, is of no value, unleſs it alſo adheres ſo firmly to the cloth, that none of the ſubſtances uſually applied to cloth in order to clean it, &c. can diſplace it. Now this can only happen when there is a ſtrong *affinity* between the colouring matter and the cloth, and when they are actually combined together in conſequence of that affinity. 400 They muſt be combined with the cloth.

4. Dyeing, then, is merely a chemical proceſs, and conſiſts in combining a certain colouring matter with the fibres of cloth. This proceſs can in no inſtance be performed, unleſs the dye ſtuff be firſt reduced to its integrant particles; for the attraction of aggregation between the particles of dye ſtuffs is too great to be overcome by the affinity between them and cloth, unleſs they could be brought within much ſmaller diſtances than is poſſible, while they both remain in a ſolid form. It is neceſſary, therefore, previouſly to diſſolve the colouring matter in ſome liquid or other, which has a weaker affinity for it than the cloth has. When the cloth is dipped into this ſolution, the colouring matter, reduced by this contrivance to a liquid ſtate, is brought within the attracting diſtance; the cloth therefore acts upon it, and by its ſtronger affinity takes it from the ſolvent, and fixes it upon itſelf. By this contrivance, too, the equality of the colour is in ſome meaſure ſecured, as every part of the cloth has an opportunity of attracting to itſelf the proper proportion of colouring particles. 401 Can only be applied in a ſtate of ſolution.

The facility with which cloth imbibes a dye, depends upon two things, namely, the affinity between the cloth and the dye ſtuff, and the affinity between the dye ſtuff and its ſolvent. It is directly as the former, and inverſely as the latter. It is of importance to preſerve a due proportion between theſe two affinities, as upon that proportion much of the accuracy of dyeing depends. If the affinity between the colouring matter and the cloth be too great, compared with the affinity between the colouring matter and the ſolvent, the cloth will take the dye too rapidly, and it will be ſcarce poſſible to prevent its colour from being unequal. On the other hand, if the affinity between the colouring matter and the ſolvent be too great, compared with that

(x) Theſe remarks hold only on the ſuppoſition, that the *whole* of the ſurface is of the given colour, which in many inſtances is not the caſe.

Dyeing in General.

that between the colouring matter and the cloth, the cloth will either not take the colour at all, or it will take it very slowly and very faintly.

Wool has the strongest affinity for almost all colouring matters, silk the next strongest, cotton a considerably weaker affinity, and linen the weakest affinity of all. Therefore, in order to dye cotton or linen, the dye stuff should in many cases be dissolved in a substance for which it has a weaker affinity than for the solvent employed in the dyeing of wool or silk. Thus we may use oxyd of iron dissolved in sulphuric acid, in order to dye wool; but for cotton and linen, it is better to dissolve it in acetous acid.

402 Nature of mordants.

5. Were it possible to procure a sufficient number of colouring matters having a strong affinity for cloth, to answer all the purposes of dyeing, that art would be exceedingly simple and easy. But this is by no means the case: if we except indigo, the dyer is scarcely possessed of a dye stuff which yields of itself a good colour sufficiently permanent to deserve the name of a dye.

This difficulty, which at first sight appears insurmountable, has been obviated by a very ingenious contrivance. Some substance is pitched upon which has a strong affinity both for the cloth and the colouring matter. This substance is previously combined with the cloth, which is then dipped into the solution containing the dye stuff. The dye stuff combines with the intermediate substance; which, being firmly combined with the cloth, secures the permanence of the dye. Substances employed for this purpose are denominated *mordants* (Y).

The most important part of dyeing is undoubtedly the proper choice and the proper application of mordants, as upon them the permanency of almost every dye depends. Every thing which has been said respecting the application of colouring matters, applies equally to the application of mordants. They must be previously dissolved in some liquid, which has a weaker affinity for them than the cloth has to which they are to be applied; and the cloth must be dipped, or even steeped, in this solution, in order to saturate itself with the mordant.

Almost the only substances used as mordants are, earths, metallic oxyds, tan, and oil.

403 Earthy mordants.

6. Of earthy mordants, by far the most important and most generally used is alumina. It was used as a mordant in very early ages, and seems indeed to have been the very first substance employed for that purpose. Alumina has a very strong affinity for wool and for silk; but its affinity for cotton and linen is a good deal weaker.

It is used as a mordant in two states; either in the state of alum, in which it is combined with sulphuric acid and a little potass; or in the state of acetite of alumina, in which it is combined with acetous acid.

Alum was employed as a mordant very early. The ancients, indeed, do not seem to have been generally acquainted with pure alum; they used it in that state of impurity in which it is found native; of course it was used in dyeing long before the nature of its ingredients was understood, and therefore long before the part which it acts was suspected. Indeed, it is but a very short time since the office which mordants perform was suspected: the first person that hit upon it was Mr Keir; he gave an account of the real use of mordants in his translation of Macquer's Dictionary, published in 1771.*

* Macquer p. 215.

Alum when used as a mordant, is dissolved in water, and very frequently a quantity of tartar is dissolved along with it. Into this solution the cloth is put and kept in it till it has absorbed as much alumina as is necessary. It is then taken out, and for the most part washed and dried. It is now a good deal heavier than it was before, owing to the alumina which has combined with it. The tartar serves two purposes; the potass which it contains combines with the sulphuric acid of the alum, and thus prevents that very corrosive substance from injuring the texture of the cloth, which otherwise might happen; the tartarous acid, on the other hand, combines with part of the alumina, and forms a tartrite of alumina, which is more easily decomposed by the cloth than alum.

Acetite of alumina has been introduced into dyeing since the commencement of the 18th century; and, like many other very important improvements, we are indebted for it to the ignorance of the calico printers, who first introduced it. As they did not understand the nature nor use of the mordants which they employed, they were accustomed to mix with their alum an immense farrago of substances a great proportion of which were injurious instead of being of service. Some one or other had mixed with alum acetite of lead: the good effects of this mixture would be soon perceived; the quantity of acetite was gradually increased, and the other ingredients omitted.* This mordant is now prepared, by pouring acetite of lead into a solution of alum: a double decomposition takes place, the sulphuric acid combines with the lead, and the compound precipitates in the form of an insoluble powder; while the alumina combines with the acetous acid, and remains dissolved in the liquid. This mordant is employed for cotton and linen, which have a weaker affinity than wool for alumina. It answers much better than alum, the cloth is more easily saturated with alumina, and takes, in consequence, both a richer and a more permanent colour.

* Bancroft p. 176.

Besides alumina, *lime* is sometimes used as a mordant. Cloth has a strong enough affinity for it; but in general it does not answer so well, as it does not give so good a colour. When used, it is either in the state of lime-water or of sulphat of lime dissolved in water.

404 Metallic mordants.

7. Almost all the metallic oxyds have an affinity for cloth; but only two of them are extensively used as mordants, namely, the oxyds of tin and of iron.

The oxyd of tin was first introduced into dyeing by Kuster (Z), a German chemist, who brought the secret to London in 1543. This period forms an era in the history of dyeing. The oxyd of tin has enabled the moderns

---

(Y) This term, imposed by the French dyers before the action of mordants was understood, signifies *biters* or *corroders*. These bodies were supposed to act merely by corroding the *cloth*. Mr Henry of Manchester has proposed to substitute the word *basis* for *mordant*; but that word is too general to answer the purpose well.

(Z) Mr Delaval has supposed, that the Tyrians were acquainted with the use of tin in dyeing, and Mr Henry ng in eral. moderns greatly to ſurpaſs the ancients in the fineneſs of their colours: by means of it alone, *ſcarlet*, the brighteſt of all colours, is produced. The method of producing the celebrated purple dye of the ancients is underſtood at preſent, and the ſhell fiſh which yield the dye ſtuff are found abundantly on the coaſts of Britain and France; but no perſon thinks now of putting the ancient mode in practice, becauſe infinitely more beautiful colours can be produced at a ſmaller price. Much of this ſuperiority is owing to the employment of the oxyd of tin.

Tin, as Prouſt has proved, is capable of two degrees of oxydation: The firſt oxyd is compoſed of 0.70 parts of tin, and 0.30 of oxygen; the ſecond, or white oxyd, of 0.60 parts of tin, and 0.40 of oxygen.* The firſt oxyd abſorbs oxygen with very great facility even from the air, and is rapidly converted into white oxyd. This fact makes it certain, that it is the white oxyd of tin alone which is the real mordant: even if the other oxyd were applied to cloth, as it probably often is, it muſt ſoon be converted into white oxyd, by abſorbing oxygen from the atmoſphere.

* . de xviii.

Tin is uſed as a mordant in three ſtates; diſſolved in nitro-muriatic acid, in acetous acid, and in a mixture of ſulphuric and muriatic acids. Nitro-muriat of tin is the common mordant employed by dyers. They prepare it by diſſolving tin in diluted nitric acid, to which a certain proportion of muriat of ſoda, or of ammonia, is added. Part of the nitric acid decompoſes theſe ſalts, combines with their baſe, and ſets the muriatic acid at liberty. They prepared it at firſt with nitric acid alone; but that mode was very defective; becauſe the nitric acid very readily converts tin to white oxyd, and then is incapable of diſſolving it. The conſequence of which was, the precipitation of the whole of the tin. To remedy this defect, common ſalt, or ſal ammoniac, was very ſoon added; muriatic acid having the property of diſſolving white oxyd of tin very readily. A conſiderable ſaving of nitric acid might be obtained, by employing as much ſulphuric acid as is juſt ſufficient to ſaturate the baſe of the common ſalt, or ſal ammoniac, employed.

When the nitro-muriat of tin is to be uſed as a mordant, it is diſſolved in a large quantity of water, and the cloth is dipped in the ſolution, and allowed to remain till ſufficiently ſaturated. It is then taken out, and waſhed and dried. Tartar is uſually diſſolved in the water along with the nitro-muriat. The conſequence of this is a double decompoſition; the nitro-muriatic acid combines with the potaſs of the tartar, while the tartarous acid diſſolves the oxyd of tin. When tartar is uſed, therefore, in any conſiderable quantity, the mordant is not a nitro-muriat, but a tartrite of tin.

Mr Hauſſman, to whom the art of dyeing lies under numerous obligations, has propoſed to ſubſtitute acetite of tin for nitro-muriat as a mordant for cotton and linen. It may be prepared by mixing together acetite of lead and nitro-muriat of tin. This mordant is preferable for theſe ſtuffs; becauſe it is much more eaſily decompoſed than the nitro-muriat.† Dyeing in General.

Dr Bancroft has propoſed to ſubſtitute a ſolution of tin in a mixture of ſulphuric and muriatic acid inſtead of nitro-muriat of tin, as a mordant for wool. This mordant, he informs us, is much cheaper, and equally efficacious. It may be prepared by diſſolving ſomewhat leſs than one part of tin in two parts of ſulphuric and three of muriatic acid, at the degree of concentration at which they are commonly ſold in this country.‡ This mordant, like the others, muſt be diſſolved in a ſufficient quantity of water, in order to be uſed.

† *Ann. de Chim.* xxv. 15.

‡ *Bancroft*, p. 290.

Iron, like tin, is capable of two degrees of oxydation; but the green oxyd abſorbs oxygen ſo readily from the atmoſphere, that it is very ſoon converted into the red oxyd. It is only this laſt oxyd which is really uſed as a mordant in dyeing. The green oxyd is indeed ſometimes applied to cloth; but it very ſoon abſorbs oxygen, and is converted into the red oxyd. This oxyd has a very ſtrong affinity for all kinds of cloth. The permanency of the iron ſpots on linen and cotton is a ſufficient proof of this. As a mordant, it is uſed in two ſtates; in that of ſulphat of iron, and acetite of iron. The firſt is commonly uſed for wool. The ſalt is diſſolved in water, and the cloth dipped in it. It may be uſed alſo for cotton; but in moſt caſes acetite of iron is preferred. It is prepared by diſſolving iron, or its oxyd, in vinegar, ſour beer, &c. and the longer it is kept, the more is it preferred. The reaſon is, that this mordant ſucceeds beſt when the iron is in the ſtate of red oxyd. It would be better then to oxydate the iron, or convert it into ruſt before uſing it; which might eaſily be done, by keeping it for ſome time in a moiſt place, and ſprinkling it occaſionally with water. Of late, pyrolignous acid has been introduced inſtead of acetous. It is obtained by diſtilling wood or tar.

8. Tan, which has been already deſcribed in the firſt part of this article, has a very ſtrong affinity for cloth, and for ſeveral colouring matters. It is therefore very frequently employed as a mordant. An infuſion of *nut galls*, or of *ſumach* (A), or any other ſubſtance containing tan, is made in water, and the cloth is dipped in this infuſion, and allowed to remain till it has abſorbed a ſufficient quantity of tan. Silk is capable of abſorbing a very great proportion of tan, and by that means acquires a very great increaſe of weight. Manufacturers ſometimes employ this method of increaſing the weight of ſilk.* 405 Tan.

Tan is often employed alſo, along with other mordants, in order to produce a compound mordant. Oil is alſo uſed for the ſame purpoſe in the dyeing of cotton and linen. The mordants, with which tan moſt frequently is combined, are alumina and oxyd of iron.

* *Berthollet*, ii. 10.

Beſides theſe mordants, there are ſeveral other ſubſtances frequently uſed as auxiliaries, either to facilitate the combination of the mordant with the cloth, or to 406 Other mordants.

ry has declared himſelf of the ſame opinion. But his reaſoning, as Dr Bancroft has ſhewn, proceeds upon a miſtake. He ſuppoſes that tin is *neceſſary* for the production of red colours.

(A) Sumach is the *rhus coriaria*; a ſhrub which is cultivated in the ſouthern parts of Europe. Its ſhoots are dried, and afterwards ground to powder: in which ſtate they are ſold to the dyer and tanner.

alter the ſhade of colour. The chief of theſe are, *tartar, acetite of lead, common ſalt, ſal ammoniac, ſulphat* or *acetite of copper*, &c.

407 Mordants affect the colour.

9. Mordants not only render the dye permanent, but have alſo conſiderable influence on the colour produced. The ſame colouring matter produces very different dyes, according as the mordant is changed. Suppoſe, for inſtance, that the colouring matter be cochineal; if we uſe the aluminous mordant, the cloth will acquire a crimſon colour; but the oxyd of iron produces with it a black. Theſe changes, indeed, might naturally have been expected: for ſince the colour of a dye ſtuff depends upon its affinity for light, every new combination into which it enters, having a tendency to alter theſe affinities, will naturally give it a new colour. Now, in all caſes, the colouring matter and mordant combine together: the colour of the cloth, then, muſt be that which the particles of the dye and of the mordant, when thus combined together, exhibit. Indeed ſome mordants may be conſidered in the light of colouring matters alſo, as they always communicate a particular colour to cloth. Thus, iron communicates a brown colour, and iron and tan together conſtitute a black dye.

In dyeing, then, it is not only neceſſary to procure a mordant, which has a ſufficiently ſtrong affinity for the colouring matter and the cloth, and a colouring matter which poſſeſſes the wiſhed for colour in perfection, we muſt procure a mordant and a colouring matter of ſuch a nature, that when *combined together* they ſhall poſſeſs the wiſhed-for colour in perfection. It is evident, too, that a great variety of colours may be produced with a ſingle dye ſtuff, provided we can change the mordant ſufficiently.

408 How applied.

10. Every thing which tends to weaken the affinity between the mordant and the cloth, or between the mordant and the colouring matter, and every thing which tends in any way to alter the nature of the mordant, muſt injure the permanency of the dye: becauſe, whenever the mordant is deſtroyed, there is no longer any thing to cauſe the dye-ſtuff to adhere; and when its nature is altered, the colour of the dye muſt alter at the ſame time. All the obſervations, then, which were made in the laſt chapter, concerning the nature of colouring matters, and the changes to which they are ſubject, apply equally to mordants. Theſe ſubſtances, indeed, are ſcarcely liable themſelves to any alteration. They are of a much more ſimple nature, in general, than dye ſtuffs; and therefore not nearly ſo liable to decompoſition. But when the colouring matter itſelf is altered it comes to the ſame thing. Its affinity for the mordant being now deſtroyed, there is nothing to retain it.

As the permanency of a dye depends upon the degree of affinity between the mordant and the colouring matter, it is clear that a dye may want permanency, even though it reſiſt the oxy-muriatic acid, and all the other ſaline teſts propoſed by chemiſts. Theſe ſubſtances may happen to have very little action on the dye ſtuff, and therefore may not affect it; yet it may ſoon diſappear, in conſequence of its want of affinity for the mordant.

11. The colouring matter with which cloth is dyed, does not cover every portion of its ſurface; its particles attach themſelves to the cloth at certain diſtances from each other; for cloth may be dyed different ſhades of the ſame colour, lighter or darker, merely by varying the quantity of colouring matter. With a ſmall quantity, the ſhade is light; and it becomes deeper as the quantity increaſes. Now this would be impoſſible, if the dye-ſtuff covered the whole of the cloth. Newton has demonſtrated, that colours are rendered faint when the rays of light which occaſion them are mixed with white rays. Conſequently, from cloth dyed of a light ſhade a conſiderable quantity of white rays paſſes off unchanged: but this could not be the caſe if the ſtuff were covered with coloured matter; becauſe all the white rays would be decompoſed as they paſs through the coloured matter. Therefore, in light ſhades, the colouring matter does not cover the cloth; its particles adhere to it, at a certain diſtance from each other, and from every part of the cloth which is uncovered, the white rays paſs off unchanged. Even when the ſhade of colour is as deep as poſſible, the colouring particles do not cover the whole of the cloth, but are at a certain diſtance from each other. This diſtance, undoubtedly, is diminiſhed in proportion to the deepneſs of the ſhade: for the deeper the ſhade, the ſmaller is the number of white rays which eſcape undecompoſed; the more, therefore, of the ſurface is covered, and, conſequently, the ſmaller is the diſtance at which each of them is placed. A ſhade may be even conceived ſo very deep, that not a particle of white light eſcapes the action of the colouring matter; in which caſe, the diſtance between the particles of colouring matter could not exceed double that diſtance at which a particle of matter is able to act upon light.

409 Dye-ſtuffs do not cover the whole ſurface of the cloth.

410 Compound colours.

That the particles of colouring matter, even when the ſhade is deep, are at ſome diſtance, is evident from this well known fact, that cloth may be dyed two colours at the ſame time. All thoſe colours, to which the dyers give the name of *compound*, are in fact two different colours applied to the cloth at once. Thus cloth gets a *green* colour, by being firſt dyed *blue* and then *yellow*. The rays of light that paſs from green cloth thus dyed are blue and yellow; by the mixture of which it is well known that green is produced. In this caſe, it is clear, that each of the colouring matters performs the very ſame office as if it were alone; and that the new colour is not produced by the combination of the two colouring matters. That part of the white light, reflected from the cloth, which paſſes through the blue colouring matter, is decompoſed, and the blue rays only tranſmitted; and that part of the white light which paſſes through the yellow colouring matter is alſo decompoſed, and only the yellow rays tranſmitted. It is clear, therefore, that both of the colouring matters equally cover the naked fibres of the cloth; conſequently the one muſt be placed in the intervals of the other: wherefore the particles of each of the colouring matters are at ſome diſtance. Now the ſame effect happens how deep ſoever the ſhade be; and it makes no difference which of the two dyes be firſt given. Nay, if one of the dyes have a ſtrong affinity for the cloth, and the other only a weak affinity, the latter will ſoon diſappear, and leave the cloth of the colour which the firſt dye gives it.

The difference, then, in the ſhade of colour, and alſo the compound colours which cloth may receive, depend entirely upon the diſtance between the particles of the colouring matters attached to the cloth, and the poſſibility

Blue. lity of partly filling up the intervals, either with the ſame colouring matter, or with a different one.

Thus we have taken a view of the theory of dyeing, as far, at leaſt, as it is at preſent underſtood. It remains for us ſtill to give an account of the particular manner by which each of the colours is imparted to cloth. This ſhall be the ſubject of the three following chapters. In the *firſt* we ſhall treat of the manner of dyeing the ſimple colours; in the *ſecond*, of dyeing the compound colours; and in the *third*, of dyeing cloth partially ſeveral different colours at the ſame time, or of that branch of the art of dyeing which is known in this country by the name of *calico printing*.

CHAP. IV. OF DYEING SIMPLE COLOURS.

THE colours denominated by dyers *ſimple*, becauſe they are the foundation of all their other proceſſes, are four; namely, 1*ſt*, blue;—2*d*, yellow;—3*d*, red;—4*th*, black. To theſe they uſually add a fifth, under the name of *root*, or brown colour. Theſe ſhall form the ſubject of the following ſections.

SECT. I. *Of Blue.*

111 :dyes. THE only colouring matters employed in dyeing blue are *woad* and *indigo*: attempts, indeed, have been made to dye with pruſſiat of iron; but theſe attempts have hitherto failed.

112 d. 1. The *iſatis tinctoria*, or *woad*, is a plant commonly enough cultivated in Scotland, and even found wild in ſome parts of England. It is of a yellowiſh colour. Some perſons think that it was this plant with which the ancient Britons ſtained their bodies, to make them appear terrible to their enemies. When arrived at maturity, this plant is cut down, waſhed, dried haſtily in the ſun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight; then well mixed together, formed into balls, which are piled upon each other, and expoſed to the wind and ſun. In this ſtate they gradually become hot, and exhale a putrid ammoniacal ſmell. The fermentation is promoted, if neceſſary, by ſprinkling the balls with water. When it has continued for a ſufficient time, the woad is allowed to fall to a coarſe powder. In this ſtate it is ſold to the dyers.

113 o. 2. Indigo, is a blue coloured powder extracted from the *indigofera tinctoria*, and from ſeveral other ſpecies of the ſame genus of plants, which are cultivated for that purpoſe both in the Eaſt and Weſt Indies.

114 pre-. When the *indigofera* has arrived at maturity, it is cut a few inches above ground, placed in ſtrata in a large veſſel, and covered with water. The plants ſoon acquire heat, ferment, and diſcharge abundance of carbonic acid gas. When the fermentation is far enough advanced, which is judged of by the paleneſs of the leaves, the liquid, now of a green colour, is decanted into large flat veſſels, where it is conſtantly agitated till blue flocculæ begin to make their appearance. Lime water is now poured in, which cauſes the blue flocks to precipitate. The colourleſs liquid is decanted off, and the blue ſediment poured into linen bags. When the water has drained from it ſufficiently, it is formed into ſmall lumps, and dried in the ſhade. In this ſtate it is ſold to the dyer under the name of *indigo*.

Dr Roxbourgh, who firſt drew the attention of manufacturers to the *nerium tinctorium*, a tree very common in Indoſtan, from the leaves of which indigo may be extracted with much advantage, has given a much ſhorter method of obtaining that pigment. The leaves are kept in a copper full of water, ſupported at the temperature of 160°, till they aſſume a yellowiſh hue, and the liquid acquire a deep green colour. The liquid is then to be drawn off, agitated in the uſual manner, till the blue flocculæ appear; and then the indigo is to be precipitated with lime water.* Blue.

This proceſs, which ſucceeds equally well with the indigofera, ſhews us that the plants, from which indigo may be extracted, contain a peculiar green pollen, ſoluble in water. The intention, both of the fermentation of the common method, and of the ſcalding, according to Dr Roxbourgh's method, is merely to extract this pollen. Mr Hauſſman firſt ſhewed, that this green baſis of indigo has a ſtrong affinity for oxygen; and the ſubſequent experiments of Drs Roxbourgh and Bancroft have confirmed his obſervations, and put them beyond the reach of doubt. It gradually attracts oxygen from the air; in conſequence of which, it acquires a blue colour, and becomes inſoluble in water. The agitation is intended to facilitate this abſorption, by expoſing a greater ſurface to the action of the air. The lime water, by abſorbing a quantity of carbonic acid, with which the green pollen ſeems to be combined, greatly facilitates the ſeparation of the indigo.

The method of preparing indigo, and of applying it to the purpoſes of dyeing, ſeems to have been very early known in India. But in Europe, though it had been occaſionally uſed as a paint,* its importance as a dye ſtuff was not underſtood before the middle of the 16th century. It is not even mentioned in the *Plictho*, which was publiſhed in 1548. At that period, then, the uſe of indigo muſt have been unknown to the Italian dyers. The Dutch were the people who firſt imported it from India, and made its importance known in Europe. It was afterwards cultivated in Mexico and the Weſt Indies with ſuch ſucceſs, that the indigo from theſe countries was preferred to every other. In conſequence of this preference, they ſupplied almoſt the whole of the European market. But within theſe few years, the Eaſt Indian indigo, owing entirely to the enlightened exertions of ſome men of ſcience, has recovered its character, and is now imported, in very conſiderable quantities, into Britain.

The indigo of commerce has different ſhades of colour, according to the manner in which it has been prepared, and the proportion of foreign ſubſtances with which it is mixed. The principal ſhades are copper colour, violet, and blue. That indigo, which has the ſmalleſt ſpecific gravity, is always moſt eſteemed; becauſe it is moſt free from impurities. Bergman† found the pureſt indigo of commerce which he could procure, compoſed of

47	pure indigo,
12	gum,
6	reſin,
22	earth,
13	oxyd of iron.
100 (B).

(B) Prouſt informs us, that he found magneſia, even abundantly, in indigo.—*Nicholſon's Jour.* III. 325.

Pure

Blue.

415 Its properties.

Pure indigo is insoluble in water, alcohol, æther, and oils: neither alkalies nor earths have any action on it; none of the acids hitherto tried have any effect on it, except the nitric and sulphuric. Nitric acid very soon converts it into a dirty white colour, and at last decomposes it completely.* When the acid is concentrated, it even sets fire to the indigo (c); when it is diluted, the indigo becomes brown, crystals make their appearance, resembling those of oxalic and tartarous acids; and there remains behind, after the acid and the crystals are washed off, a viscid substance, of a very bitter taste, and possessing many of the properties of a resin.†

* *Berg.* v. 3.

† *Haussmann.*

Concentrated sulphuric acid dissolves indigo readily, and much heat is evolved. The saturated solution is opaque, and consequently black; but it assumes a deep blue colour when diluted with water. This solution is well known in commerce under the name of *liquid blue.* Bancroft has given it the name of *sulphat of indigo.* During the solution of the indigo, some sulphurous acid, and some hydrogen gas, are evolved,‡ and the blue colour of the indigo is much heightened. These facts have led Bancroft to suppose, that the indigo, during its solution, combines with an additional quantity of oxygen.* This *may* possibly be the case, but the phenomena are not sufficient to establish it: for the hydrogen gas and sulphurous acid evolved may owe their formation, not to the action of the sulphuric acid on indigo, but upon the impurities with which it is always mixed; and the improvement of the colour may be owing to the absence of these impurities. The carbonats of fixed alkalies precipitate slowly from sulphat of indigo a blue coloured powder, which possesses the properties of indigo; but it is soluble in most acids and in alkalies. Pure alkalies destroy the colour and properties of sulphat of indigo: they destroy also precipitated indigo.§ These facts give some probability to Bancroft's opinion; but they do not establish it: because the differences between common and precipitated indigo may depend merely on the state of greater minuteness to which it is reduced, which prevents the attraction of aggregation from obstructing the action of other bodies. Even silica, when newly precipitated, is soluble in many menstrua.

§ *Berg.* v. 7.

416 Method of dyeing with sulphat of indigo.

3. Indigo has a very strong affinity for wool, silk, cotton and linen. Every kind of cloth, therefore, may be dyed with it, without the assistance of any mordant whatever. The colour thus induced is very permanent; because the indigo is already saturated with oxygen, and because it is not liable to be decomposed by those substances, to the action of which the cloth is exposed. But it can only be applied to cloth in a state of solution; and the only solvent known being sulphuric acid, it would seem at first sight that the sulphuric acid solution is the only state in which indigo can be employed as a dye.

The sulphat of indigo is indeed often used to dye wool and silk blue; but it can scarcely be applied to cotton and linen, because the affinity of these substances for indigo is not great enough to enable them readily to decompose the sulphat. The colour given by sulphat of indigo is exceedingly beautiful: it is known by the name of Saxon blue; because the process, which was discovered by councellor Barth in 1740, was first carried on at Grossenhayn in Saxony. The method of the original inventor was very complicated, from the great number of useless ingredients which were mixed with the sulphat. But these ingredients were gradually laid aside, and the composition simplified by others, after the nature of it, which was for some time kept secret, became known to the public. The best process is that of Mr Poerner.*

* *Instruct. sur l'Art la Teinture,* p. 183.

One part of indigo is to be dissolved in four parts of concentrated sulphuric acid; to the solution one part of dry carbonat of potass is to be added, and then it is to be diluted with eight times its weight of water. The cloth must be boiled for an hour in a solution, containing five parts of alum and three of tartar for every 32 parts of cloth. It is then to be thrown into a water bath, containing a greater or smaller proportion of the diluted sulphat of indigo, according to the shade which the cloth is intended to receive. In this bath it must be boiled till it has acquired the wished-for colour. The alum and tartar are not intended to act as mordants, but to facilitate the decomposition of the sulphat of indigo. Bergman ascertained that alum possesses this property. The alkali added to the sulphat answers the same purpose. These substances, also, by saturating part of the sulphuric acid, serve, in some measure, to prevent the texture of the cloth from being injured by the action of the acid, which is very apt to happen in this process.

4. But sulphat of indigo is by no means the only solution of that pigment employed in dyeing. By far the most common method, and indeed the only method known before 1740, is to deprive indigo of the oxygen to which it owes its blue colour, and thus to reduce it to the state of green pollen; and then to dissolve it in water by means of alkalies, or alkaline earths, which in that state act upon it very readily. Indigo is precisely in the state of green pollen when it is first extracted from the plant in the scalding process described by Dr Roxbourgh. If, therefore, there were any method of stopping short here, and of separating the pigment while it retains its green colour, it would be precisely in the state best adapted for dyeing. Nothing more would be necessary but to dissolve it in water by means of an alkali, and to dip the cloth into the solution.† 417

417 Method of dyeing by decomposing indigo.

† *Bancroft.*

But as indigo is not brought home to us in that state, the dyer is under the necessity of undoing the last part of the indigo maker's process, by separating again the oxygen, and restoring it to its original green colour. Two different methods are employed for this purpose. The first of these methods is to mix with indigo a solution of some substance which has a stronger affinity for oxygen than the green basis of indigo. Green oxyd of iron, for instance, and different metallic sulphurets. If, therefore, indigo, lime, and green sulphat of iron, be mixed together in water, the indigo gradually

(c) The combustion of indigo by nitric acid, of the density 1.52°, was first published by Mr Sage; but Woulfe appears to have observed the fact before him, and to have pointed it out to Rouelle, who shewed it in his lectures. *Proust, Nicholson's Jour.* III. 325.

ue. gradually loſes its blue colour, becomes green, and is diſſolved, while the green oxyd of iron is converted into the red oxyd. The manner in which theſe changes take place is obvious. Part of the lime decompoſes the ſulphat of iron; the green oxyd, the inſtant that it is ſet at liberty, attracts oxygen from the indigo, decompoſes it, and reduces it to the ſtate of green pollen. This green pollen is immediately diſſolved by the action of the reſt of the lime. In like manner, indigo is diſſolved, when mixed in water, with pure antimony and potaſs, or with ſulphuret of arſenic and potaſs. For theſe intereſting facts we are indebted to Mr Hauſſman.

The ſecond method is to mix the indigo in water with certain vegetable ſubſtances which readily undergo fermentation. During this fermentation, the indigo is deprived of its oxygen, and diſſolved by means of quicklime or alkali, which is added to the ſolution. The firſt of theſe methods is uſually followed in dyeing cotton and linen; the ſecond, in dyeing wool and ſilk.

18 to in- a blue r ou 5. In the dyeing of wool, woad and bran are commonly employed as vegetable ferments, and lime as the ſolvent of the green baſe of the indigo. Woad contains itſelf a colouring matter preciſely ſimilar to indigo; by following the common proceſs, indigo may be extracted from it. In the uſual ſtate of woad, when purchaſed by the dyer, the indigo which it contains is probably not far from the ſtate of green pollen. Its quantity in woad is but ſmall, and it is mixed with a great proportion of other vegetable matter. Before the introduction of indigo into Europe, woad alone was employed as a blue dye; and even as late as the 17th century, the uſe of indigo was reſtricted in different countries, and dyers obliged to employ a certain quantity of woad (D). But theſe abſurd reſtrictions were at laſt removed, and woad is now ſcarcely uſed in dyeing, except as a ferment to indigo. The blue colouring matter, however, which it contains, muſt, in all caſes, contribute conſiderably to the dye.

A ſufficient quantity of woad, mixed with bran, is put into a wooden veſſel filled with warm water, whoſe temperature is kept up ſufficiently to enſure fermentation. Afterwards quicklime and indigo are added. The indigo is deprived of its oxygen, and diſſolved by the lime. When the ſolution is complete, the liquid has a green colour, except at the ſurface, where it is copper coloured, or blue, becauſe the indigo at the ſurface abſorbs oxygen from the air, and aſſumes its natural colour. The woollen cloth is dipped in, and paſſed thro' the liquid as equably as poſſible, piece after piece; thoſe pieces being firſt dyed which are to aſſume the deepeſt ſhade. No part of the cloth ſhould come in contact with the ſediment, which would ſpoil the colour. When the cloth is firſt taken out of the vat, it is of a green colour; but it ſoon becomes blue, by attracting oxygen from the air. It ought to be carefully waſhed, to carry off the uncombined particles. This ſolution of indigo is liable to two inconveniences: 1. It is apt ſometimes to run too faſt into the putrid fermentation: this may be known by the putrid vapours which it exhales, and by the diſappearing of the green colour. In this ſtate it would ſoon deſtroy the indigo altogether. The inconvenience is remedied by adding more lime, which has the property of moderating the putreſcent tendency. 2. Sometimes the fermentation goes on too languidly. This defect is remedied by adding more bran or woad, in order to diminiſh the proportion of quicklime.

6. Silk is uſually dyed blue by the following proceſs: Six parts of bran, and ſix of indigo, with nearly one part of madder, are ſtirred into a ſufficient quantity of water, in which ſix parts of common potaſh of commerce is diſſolved. The liquid is kept at a temperature proper for fermentation. When the indigo, deprived of its oxygen by the fermentation, is diſſolved by the potaſs, the liquid aſſumes a green colour. The ſilk, previouſly well ſcoured, is put into the ſolution in ſmall quantities at a time; then wrung out of the dye, and hung up in the open air, till the green colour which it has at firſt is changed into blue. By this method, ſilk can only be made to receive a light blue colour. In order to give ſilk a dark blue, it muſt previouſly receive what is called a ground colour; that is, be previouſly dyed ſome other colour. A particular kind of red dye-ſtuff, called *archil* (E), is commonly employed for this purpoſe. 419. Silk.

The madder employed in the above proceſs may, at firſt ſight, appear ſuperfluous; it ſeems, however, to contribute ſomething to the colour.

7. Cotton and linen are dyed blue by the following proceſs: One part of indigo, one part of green ſulphat of iron, and two parts of quicklime, are ſtirred into a ſufficient quantity of water. The ſolution is at firſt green, but it gradually aſſumes a yellow colour, and its ſurface is covered with a ſhining copper coloured pellicle. The cloth is to be allowed to remain in the ſolution for five or ſix minutes. When taken out, it has a yellow colour; but on expoſure to the atmoſphere, it ſoon becomes green, and then blue, in conſequence of the abſorption of oxygen. The indigo, in this proceſs, ſeems to be deprived of a greater quantity of oxygen than is neceſſary to reduce it to the ſtate of green pollen. Mr Hauſſman has obſerved, that the cloth acquires a much deeper colour, provided it be plunged, the inſtant it is taken out of the dyeing vat, into water acidulated with ſulphuric acid. It is uſual to dip the cloth into a ſucceſſion of vats, variouſly charged with colouring matter; beginning with the vat which contains leaſt colouring matter, and paſſing gradually to thoſe which contain moſt. By this contrivance the cloth is dyed more equally, than it probably would be, if it were plunged all at once into a ſaturated ſolution of colouring matter. 420 Cotton, and linen.

SECT. II. *Of Yellow.*

THE principal colouring matters employed to dye yellow are *weld*, *fuſtic*, and *quercitron bark*. 421 Yellow dyes.

1. Reſeda luteola, known in this country by the name of

(D) The employment of indigo was ſtrictly prohibited in England in the reign of Queen Elizabeth; nor was the prohibition taken off till the reign of Charles II. It was prohibited alſo in Saxony. In the edict it is ſpoken of as a corroſive ſubſtance, and called *food for the devil*. Colbert reſtricted the French dyers to a certain quantity of it.

(E) This will be deſcribed in a ſubſequent ſection.

Yellow. of *weld*, is a plant which grows wild very commonly in Scotland, and in most European countries. Cultivated weld has a more slender stem than the wild kind, but it is more valuable, because it is much more rich in colouring matter. It is an annual plant, of a yellowish green colour, furnished with a great number of small leaves. When ripe it is pulled, dried, tied up in parcels, and in that state sold to the dyer.

422 Weld.

Weld readily yields its colouring matter to water. The saturated decoction of it is brown; but when sufficiently diluted with water it becomes yellow. Acids render its colour somewhat paler, but alkalies give it a deeper shade. When alum is added to it, a yellow coloured precipitate falls down, consisting of alumina combined with the colouring matter of weld. The affinity therefore of this colouring matter for alumina is so great, that it is able to abstract it from sulphuric acid. Its affinity for oxyd of tin is at least equally great; for muriat of tin causes a copious bright yellow precipitate, composed of the colouring matter and the oxyd combined. Most of the metallic salts occasion similar precipitates, but varying in colour according to the metal employed. With iron, for instance, the precipitate is dark grey, and with copper brownish green.*

* *Berthollet*, ii. 260.

423 Fustic.

2. The *morus tinctoria* is a large tree which grows in the West India islands. The wood of this tree is of a yellow colour, with orange veins. The French call it *yellow wood (bois jaune)*; but the English dyers have given it the absurd name of *old fustic* (F). This wood has been introduced into dyeing since the discovery of America. The precise time is not known; but that it was used in England soon after the middle of the 17th century, is evident from Sir William Petty's paper on *Dyeing*, read to the Royal Society soon after its institution. In that paper particular mention is made of *old fustic*.

Fustic gives out its colouring matter with great facility to water. The saturated decoction of it is of a deep reddish yellow colour; when sufficiently diluted it becomes orange yellow. Acids render it turbid, give it a pale yellow colour, and occasion a slight greenish precipitate, which alkalies redissolve. Alkalies give the decoction a very deep colour, inclining to red; some time after they have been added, a yellow matter separates from the liquid, and either swims on the surface, or adheres to the sides of the vessel. Alum, sulphat of iron, of copper, and of zinc, produce precipitates composed of the colouring matter combined respectively with the bases of these different salts; and the colour varies according to the substance with which this colouring matter is combined. With alumina it is yellow; with iron, yellowish brown; with copper, brownish yellow; and with zinc, greenish brown.†

† *Id.* ii. 269.

424 Quercitron.

3. The *quercus nigra*, to which Dr Bancroft has given the name of *quercitron*, is a large tree which grows naturally in North America. Dr Bancroft discovered, about the year 1784, that the bark of this tree contains a great quantity of yellow colouring matter, and since that time it has been introduced into dyeing with much advantage. To prepare it for the dyer, the epidermis is shaved off, and then it is ground in a mill. It separates partly into stringy filaments, and partly into a fine light powder. Both of these contain colouring matter, and therefore are to be employed; but as they contain unequal quantities, they should be used in their natural proportions.

Quercitron bark readily gives out its colouring matter to water at the temperature of 100°. The infusion has a yellowish brown colour, which is rendered lighter by acids, and darker by alkalies. Alum occasions a scanty precipitate of a deep yellow colour; muriat of tin, a copious bright yellow precipitate; sulphat of tin, a dark olive precipitate; and sulphat of copper, a precipitate of a yellow colour inclining to olive.‡

‡ *Bancr* i. 320.

425 Other yellow dy[e stuffs].

4. Besides these dye stuffs there are others occasionally used by dyers. The following are the most remarkable:

Genista tinctoria, or *dyers broom*. This plant yields a very inferior yellow; it is only used for coarse woollen stuffs.

Serratula tinctoria, or *saw-wort*. This plant yields a yellow nearly of the same nature with *weld*; for which, therefore, it is a good substitute.

Juglans alba, or *American hiccory*. The bark of this tree yields a colouring matter exactly similar to that of quercitron bark, but much smaller in quantity.

Anotta is a name given to a red paste formed of the berries of the bixa orellana, a tree which is a native of America. This paste yields its colouring matter to a solution of alkali in water. The solution affords an exceedingly beautiful yellow dye, but very fading, and incapable of being fixed by any known mordant.

Turmeric is the root of the *curcuma longa*, a plant which grows both in the East and West Indies. It is richer in colouring matter than any other yellow dye stuff. It yields very beautiful yellows, but too fading to be of much use, and no mordant has any influence in contributing to their permanence.

426 Yellow [re]quires mordan[ts].

5. Yellow colouring matters have too weak an affinity for cloth to produce permanent colours without the use of mordants. Cloth, therefore, before it be dyed yellow, is always prepared by combining some mordant or other with it. The mordant most commonly employed for this purpose is alumina. Oxyd of tin is sometimes used when very fine yellows are wanted. Tan is often employed as a subsidiary to alumina, in order to fix it more copiously on cotton and linen. Tartar is also used as an auxiliary to brighten the colour; and muriat of soda, sulphat of lime, and even sulphat of iron, in order to render the shade deeper.

6. The yellow dyed by means of fustic is more permanent, but not so beautiful as that given by weld or quercitron. As it is permanent, and not much injured by acids, it is often used in dyeing compound colours where

(F) The *rhus cotinus*, or Venice sumach, is a small shrub, formerly employed as a yellow dye, but now almost out of use. The French call it *fustet*, from which word it is probable, as Dr Bancroft supposes, that our dyers formed the term *fustic*. When the *morus tinctoria* was introduced as a dye-stuff, they gave it the same name: but in order to distinguish the two, they called the sumach, which was a small shrub, *young fustic*; and the morus, which was a large tree, *old fustic*. See *Bancroft*, i. 412.

ow. where a yellow is required. The mordant is alumina. When the mordant is oxyd of iron, fustic dyes a good permanent drab colour.

. Weld and quercitron bark yield nearly the same kind of colour; but as the bark yields colouring matter in much greater abundance, it is much more convenient, and, upon the whole, cheaper than weld. It is probable, therefore, that it will gradually supersede the use of that plant. The method of using each of these dye stuffs is nearly the same.

7
d of
g a
co-

7. Wool may be dyed yellow by the following process: Let it be boiled for an hour, or more, with about $\frac{1}{6}$th of its weight of alum, dissolved in a sufficient quantity of water. It is then to be plunged, without being rinced, into a bath of warm water, containing in it as much quercitron bark as equals the weight of the alum employed as a mordant. The cloth is to be turned through the boiling liquid till it has acquired the intended colour. Then a quantity of clean powdered chalk, equal to the hundredth part of the weight of the cloth, is to be stirred in, and the operation of dyeing continued for eight or ten minutes longer. By this method a pretty deep and lively yellow may be given
roft, fully as permanent as weld yellow.*

. For very bright *orange*, or golden *yellows*, it is necessary to have recourse to the oxyd of tin as a mordant. A fine orange yellow may be given to woollen cloth, by putting, for every ten parts of cloth, one part of bark into a sufficient quantity of hot water; after a few minutes, an equal weight of murio-sulphat of tin is to be added, and the mixture well stirred. The cloth acquires the wished-for colour in a few minutes when
329. briskly turned in this bath.†

The same process will serve for producing *bright golden yellows*, only some alum must be added along with the tin. For the brightest golden yellow, the proportions sufficient for dyeing 100 parts of cloth are, 10 parts of bark, 7 parts of murio-sulphat of tin, and 5 parts of alum. All the possible shades of golden yellow may be given to cloth merely by varying the propor-
330. tion of the ingredients according to the shade.‡

In order to give the yellow that delicate *green* shade so much admired for certain purposes, the same process may be followed, only tartar must be added in different proportions according to the shade. Thus to dye 100 parts of cloth a *full bright yellow*, delicately inclining to *green*, 8 parts of bark, 6 of murio-sulphat, 6 of alum, and 4 of tartar, are to be employed. The tartar is to be added at the same time with the other mordants. If the proportion of alum and tartar be increased, the green shade is more lively: to render it as lively as possible, all the four ingredients ought to be employed in equal proportions. As these fine lemon-yellows are generally required only pale, 10 parts of each of the ingredients will be sufficient to dye about 300 parts of cloth.§

By adding a small proportion of cochineal, the co-
335. lour may be raised to a fine orange, or even an aurora‖.

28
lk,

8. Silk may be dyed different shades of yellow, either by weld or quercitron bark, but the last is the cheapest of the two. The proportion should be from 1 to 2 parts of bark to 12 parts of silk, according to the shade. The bark, tied up in a bag, should be put into the dyeing vessel while the water which it contains is cold, and when it has acquired the heat of about 100°, the silk, previously alumed, should be dipped in, and continued till it assumes the wished-for colour. When the shade required is deep, a little chalk or pearl ash should be added towards the end of the operation. When a very lively yellow is wanted, a little murio-sulphat of tin should be added, but not too much, because tin always injures the glossiness of silk. The proportions may be 4 parts of bark, 3 of alum, and 2 of murio-sulphat of tin.¶

Yellow.

Silk is dyed fine orange and aurora colours by annotta. The process is merely dipping the silk into an alkaline solution of annotta. To produce the orange shade the alkali is saturated with lemon juice. The colours thus produced are exceedingly beautiful, but they want permanency. 429

Cotton, and linen.

9. The common method of dyeing cotton and linen yellow, has been described in the article DYEING in the *Encyclopædia*. The cloth is first soaked in a solution of alum, and then dyed in a decoction of weld. After this it is soaked for an hour in a solution of sulphat of copper, and, lastly, it is boiled for an hour in a solution of hard soap. This process, besides the expence of it, is defective; because the yellow is neither so beautiful nor so permanent as it might be if the mordant were used in a different form.

The method recommended by Dr Bancroft is much more advantageous, yielding more permanent and beautiful colours at a smaller expence. The mordant should be acetite of alumina, prepared by dissolving 1 part of acetite of lead, and 3 parts of alum, in a sufficient quantity of water. This solution should be heated to the temperature of 100°, the cloth should be soaked in it for two hours, then wrung out and dried. The soaking may be repeated, and the cloth again dried as before. It is then to be barely wetted with lime water, and afterwards dried. The soaking in the acetite of alumina may be again repeated; and if the shade of yellow is required to be very bright and durable, the alternate wetting with lime water, and soaking in the mordant, may be repeated three or four times. By this contrivance a sufficient quantity of alumina is combined with the cloth, and the combination is rendered more permanent by the addition of some lime. The dyeing bath is prepared by putting 12 or 18 parts of quercitron bark (according to the depth of the shade required), tied up in a bag, into a sufficient quantity of cold water. Into this bath the cloth is to be put, and turned round in it for an hour, while its temperature is gradually raised to about 120°. It is then to be brought to a boiling heat, and the cloth allowed to remain in it after that only a few minutes. If it be kept long at a boiling heat the yellow acquires a shade of brown*.

Another way of dyeing cotton and linen very permanent yellows, would be to imitate the method adopted for dyeing cotton in the East. That method is indeed exceedingly tedious, but it might be very much shortened by carefully attending to the uses of the ingredients. The essential part of the process is to cause the alumina to combine in sufficient quantity with the cloth, and to adhere with sufficient firmness to ensure a permanent colour. This is accomplished by using three mordants; first oil, then tan, and lastly alum. The combination of these three substances produces a mordant which ensures a very permanent colour.

The cotton is first soaked in a bath composed of a sufficient quantity of oil, and mixed with a weak solu-
tion,

¶ Bancroft, i. 345.

* Ibid. 351.

Yellow. tion of soda. Animal oil seems to answer best for the purpose. Vogler found that glue answered extremely well. The soda should be caustic: In that state it combines with the oil, and enables the cloth to absorb it equally. It is then, after being washed, put into an infusion of nut galls (the whiter the better). The tan combines with the oil, while the gallic acid carries off the alkali that may remain attached to the cloth. The infusion ought to be hot; and the cotton, after coming out of it, should be dried as quickly as possible. Care should be taken that the quantity of galls do not exceed a just proportion compared with the oil, otherwise the colour will be darkened. The cotton, thus prepared, is to be put into a solution of alum. There is a strong affinity between tan and alumina; in consequence of which, the alum is decomposed, and the alumina combines with the tan in sufficient abundance.† The cotton, thus prepared, is to be dyed, as above described, with quercitron bark.

† *Chaptal, Ann. de Chim.* xxvi. 251.

430 Chaptal's process for cotton. Mr Chaptal, whose ingenious labours have contributed exceedingly to elucidate the theory of dyeing, has proposed an exceedingly simple and cheap method of dyeing cotton a fine permanent nankeen yellow. His process is as follows (G).

Cotton has so strong an affinity for oxyd of iron, that if put into a solution of that oxyd in any acid whatever, it decomposes the salt, absorbs the iron, and acquires a yellow colour. The cotton to be dyed is to be put into a cold solution of sulphat of iron, of the sp. gr. 1.020; it is then wrung out, and put directly into a ley of potass, of the sp. gr. 1.010, into which a solution of alum has been poured till it was saturated with it. After the cotton has remained in this bath four or five hours, it may be taken out, washed, and dried. By this process cotton may be dyed all the different shades of nankeen, by varying the proportion of the sulphat of iron. This colour has the advantage of not being injured by washing, and of being exceedingly cheap.§

§ *Ibid.* 270.

SECT. III. *Of Red.*

431 Red dyes. THE principal colouring matters employed in dyeing *red* are, *kermes*, *cochineal*, *archil*, *madder*, *carthamus*, and *Brazil wood*.

432 Kermes, 1. In different parts of Asia and the south of Europe, there grows a small species of oak, to which Linnæus gives the name of *quercus coccifera*. On this oak resides a small insect, of a reddish brown colour; in commerce it is known by the name of *kermes*. This insect is a species of *coccus*: Linnæus called it *coccus ilicis*. These insects are gathered in the month of June, when the female, which alone is useful, is swelled with eggs. They are steeped for ten or twelve hours in vinegar to kill the young insects contained in the eggs, and afterwards dried on a linen cloth. In this state they are sold to the dyer.

Kermes readily gives out its colouring matter to water or alcohol. It was much used by the ancients in dyeing; the colours which it produced were highly esteemed, being inferior in price only to their celebrated purple. They gave it the name of *coccus*.

Red. The colour which it communicates to cloth is exceedingly permanent, but being far inferior in beauty to those which may be obtained from cochineal, it has been but little employed by dyers since that splendid pigment came into common use.

433 Cochineal. 2. Cochineal is likewise an insect, a species of *coccus*. Linnæus distinguishes it by the name *coccus cacti*. It inhabits different species of cacti, but the most perfect variety is confined to the *cactus coccinillifer*. The cochineal insect was first discovered in Mexico; the natives had employed it in their red dyes before the arrival of the Spaniards. It became known in Europe soon after the conquest of Mexico; and the beauty of the colour which it communicates to cloth very soon attracted general attention. For many years it was mistaken for a vegetable production, as had been the case also with the kermes. Different accounts of its real nature had indeed appeared very early in the Philosophical Transactions; but the opinion of Pomet, who insisted that it was the seed of a particular plant, gained so much credit, that it was not entirely destroyed till the publication of Mr Ellis's paper in the 52d volume of the Philosophical Transactions, which established the contrary beyond the possibility of doubt.

The female cochineal insect remains like the kermes, during her whole life adhering to a particular spot of the tree on which it feeds. After fecundation, her body serves merely as a nidus for her numerous eggs, and gradually swells as these advance towards maturity. In this state the insects are gathered, put into a linen bag, which is dipt into hot water to destroy the life of the young animals contained in the eggs, and then dried. In this state they are sent to Europe and sold to the dyer.

The quantity of cochineal disposed of in Europe is very great. Bancroft informs us, that the Spaniards annually bring to market about 600,000 lbs. of it. Hitherto the rearing of the insects has belonged almost exclusively to that nation. Other nations have indeed attempted to share it with them, but without any remarkable success; as the Spaniards use every precaution to confine the true cochineal, and even the species of cactus on which it feeds, to Mexico. Mr Thiery de Menonville was fortunate enough to procure some specimens of both, and to transfer them in safety to St Domingo; but after his death, the insects were allowed to perish. The wild cochineal insect, which differs from the cultivated kind merely in being smaller, and containing less colouring matter, was produced in St Domingo, in considerable quantities, before the commencement of the present war. Several spirited British gentlemen have lately contrived to procure the insect; and vigorous efforts are making to rear it in the East Indies. We have not yet learned the success of these attempts; but we have reason to hope every thing from the zeal and abilities of those gentlemen who have taken an active part in the enterprize.

Cochineal readily gives out its colouring matter to water. The decoction is of a crimson colour, inclining to violet: It may be kept for a long time without putrifying or losing its transparency. Sulphuric acid gives

(G) We ought to mention, that this process, or at least one very similar, has been long well known to the calico printers of this country. Most of their brown yellows, or drabs, are dyed with iron.

l. gives it a red colour, inclining to yellow, and occasions a small fine red precipitate. Tartar gives it a yellowish red colour, which becomes yellow after a small quantity of red powder has subsided. Alum brightens the colour of the decoction, and occasions a crimson precipitate. Muriat of tin gives a copious fine red precipitate; sulphat of iron, a brownish violet precipitate; sulphat of zinc, a deep violet precipitate; acetite of lead, and sulphat of copper, violet precipitates.†

bollet, i.

Water is not capable of extracting the whole of the colouring matter of cochineal; but the addition of a little alkali or tartar enables the water to extract the whole of it.*

175.

un- 271.

3. Archil (H) is a paste formed of the *lichen roccella*, pounded and kept moist for some time with stale urine. It gives out its colouring matter to water, to alcohol (I), and to a solution of ammonia in water.

4 il,

The lichen roccella grows abundantly in the Canary islands, from which it is imported and sold to the dyers. Other lichens are likewise used to dye red, especially the *parellus*, from which the pigment called *litmus*, and by chemists *turnsole*, is prepared; the *omphalodes* and *tartareus*, which are often employed in this country to dye coarse cloths. To these many others might be added; but the reader may consult the treatises of Hoffman and Westring on the subject.

5 der,

4. The *rubia tinctorum* is a small well known plant, cultivated in different parts of Europe for the sake of its roots, which are known by the name of *madder*. They are about the thickness of a goose quill, somewhat transparent, of a reddish colour, and a strong smell. They are dried, cleaned, ground in a mill, and in that state used by dyers.

Madder gives out its colouring matter to water. The infusion is of a brownish orange colour; alum produces in it a deep brownish red precipitate; alkaline carbonats, a blood red precipitate, which is redissolved on adding more alkali. The precipitate occasioned by acetite of lead is brownish red; by nitrat of mercury, purplish brown; by sulphat of iron, a fine bright brown. After the red colouring matter has been extracted from madder by water, it is still capable of yielding a brown colour.‡

ollet, i.

6 amus.

5. *Carthamus tinctorius* is an annual plant, cultivated in Spain, Egypt, and the Levant, for the sake of its flowers, which alone are used in dyeing. After the juice has been squeezed out of these flowers, they are washed repeatedly with salt water, pressed between the hands, and spread on mats to dry. Care is taken to cover them from the sun during the day, and to expose them to the evening dews, in order to prevent them from drying too fast. Such is the method followed in Egypt.

Red.

The flowers of carthamus contain two colouring matters; a yellow, which is soluble in water, and a red, insoluble in water, but soluble in alkaline carbonats. The method of preparing them above described, is intended to carry off the yellow colouring matter, which is of no use, and to leave only the red. After the flowers are thus prepared, they are of a red colour, and have lost nearly one-half of their weight. An alkaline ley readily extracts their colouring matter, which may be precipitated by saturating the alkali with an acid. Lemon juice is commonly used for this purpose, because it does not injure the colour of the dye. Next to citric, sulphuric acid is to be preferred, provided too great a quantity be not used. The red colouring matter of carthamus, extracted by carbonat of soda, and precipitated by lemon juice, constitutes the *rouge* employed by the ladies as a paint. It is afterwards ground with a certain quantity of talc. The fineness of the talc, and the proportion of it mixed with the carthamus, occasion the difference between the cheaper and dearer kinds of *rouge*.

6. *Brazil wood*, or *fernambouc*, as it is called by the French, is the wood of the *cæsalpinia crista*, a tree which grows naturally in America and the West Indian islands. It is very hard; its specific gravity is greater than that of water; its taste is sweetish: its colour, when fresh cut, is pale; but after exposure to the atmosphere, it becomes reddish. 437 Brazil wood.

Brazil wood yields its colouring matter to alcohol, and likewise to boiling water. The decoction is of a fine red colour. The mineral acids make it yellow, and occasion a reddish brown precipitate. Oxalic acid causes an orange red precipitate. Fixed alkali gives the decoction a crimson colour, inclining to brown; ammonia, bright purple. Alum occasions a copious crimson precipitate, especially if alkali is added at the same time. Sulphat of iron renders the decoction black. The precipitate produced by muriat of tin is rose coloured; that by acetite of lead of a fine deep red.*

* *Berthollet*, ii. 240.

The decoction of Brazil wood is fitter for dyeing after it has stood some time, and undergone a kind of fermentation.

7. None of the red colouring matters has so strong an affinity for cloth as to produce a permanent red, without the assistance of mordants. The mordants employed are alumina and oxyd of tin; oil and tan, in certain processes, are also used; and tartar and muriat of soda are frequently called in as auxiliaries. 438 Red requires a mordant.

8. Coarse woollen stuffs are dyed red with madder or

(H) If we believe Tournefort, this dye stuff was known to the ancients. They employed it to dye the colour known by the name of *purple* of Amorgos, one of the Cyclades islands. If this account be accurate, the knowledge of it had been lost during the dark ages. It was accidentally discovered by a Florentine merchant about the year 1300, who observed, that urine gave a very fine colour to the lichen roccella. Mr Dufay discovered, that archil possesses the property of tinging indelibly white marble, of forming veins, and giving it the appearance of jasper. See *Mem. Par.* 1732.

(I) The tincture of archil is used for making *spirit of wine thermometers*. It is a singular fact, that this tincture becomes gradually colourless when excluded from the contact of air, and that it again recovers its colour when exposed to the atmosphere. The phenomenon was first observed by the Abbé Nollet, and described by him in an essay, published among the memoirs of the Academy of Sciences for 1742.

Red.

or archil; but fine cloth is almost exclusively dyed with cochineal; though the colour which it receives from kermes is much more durable. Brazil wood is scarcely used, except as an auxiliary; because the colour which it imparts to wool is not permanent.

439 Wool how dyed crimson,

Wool is dyed *crimson*, by first impregnating it with alumina by means of an alum bath, and then boiling it in a decoction of cochineal till it has acquired the wished-for colour. The crimson will be finer if the tin mordant be substituted for alum: indeed it is usual with dyers to add a little nitro-muriat of tin when they want fine crimsons. The addition of archil and potass to the cochineal, both renders the crimson darker and gives it more bloom; but the bloom very soon vanishes. For paler crimsons, one-half of the cochineal is withdrawn, and madder substituted in its place.

440 And scarlet.

Wool may be dyed *scarlet*, the most splendid of all colours, by first boiling it in a solution of murio-sulphat of tin; then dyeing it pale yellow with quercitron bark, and afterwards crimson with cochineal: For scarlet is a compound colour, consisting of *crimson* mixed with a little *yellow*. This method was suggested by Dr Bancroft, who first explained the nature of the common method. The proportions which he gives are eight parts of murio-sulphat of tin for 100 parts of cloth. After the cloth has been boiled in this solution for a quarter of an hour, it is to be taken out, and about four parts of cochineal, and two and a half parts of quercitron bark, are to be thrown into the bath. After these are well mixed, the cloth is to be returned again to the bath, and boiled in it, till it has acquired the proper colour.*

* *Bancroft*, i. 291.

The common process for dyeing scarlet is as follows: Twelve parts of tartar are dissolved in warm water; then one part of cochineal is added, and soon after ten parts of nitro-muriat of tin. When the bath boils, 100 parts of cloth are put in, turned briskly through the bath, boiled in it for two hours; then taken out, aired, washed, and dried. Into another bath eleven parts of cochineal are put; and after its colouring matter is sufficiently extracted, 28 parts of nitro-muriat of tin are added. In this bath the cloth is boiled for an hour, and then washed and dried.

Every preceding writer on dyeing took it for granted, that the yellow tinge necessary for scarlet was produced by the nitro-muriat of tin, or rather by the nitric acid of that compound, and that the tartar was only useful in enlivening the colour. But Dr Bancroft ascertained, by actual experiment, that nitro-muriat of tin has no such effect; that cloth, impregnated with this or any other tin mordant, and afterwards dyed with cochineal, acquires only a crimson colour, unless tartar be added; that the tartar has the property of converting part of the cochineal to yellow; and therefore is the real agent in producing the scarlet colour. Good scarlet, indeed, cannot be made without tin; because every other mordant sullies the colour, and renders it dull.†

† *Ibid.* 288.

441 Red dyes employed for silk,

9. Silk is usually dyed red with cochineal or carthamus, and sometimes with Brazil wood. Kermes does not answer for silk; madder is scarcely ever used for that purpose, because it does not yield a bright enough colour. Archil is employed to give silk a bloom; but it is scarcely used by itself, unless when the colour wanted is lilac.

Red.

442 In dyeing crimson,

Silk may be dyed crimson by steeping it in a solution of alum, and then dyeing it in the usual way in a cochineal bath. But the common process is to plunge the silk, after it has been alumed, into a bath formed of the following ingredients: Two parts of white galls, three parts of cochineal, three-sixteenths of tartar, and three-sixteenths of nitro-muriat of tin, for every sixteen parts of silk. The ingredients are to be put into boiling water in the order they have been enumerated; the bath is then to be filled up with cold water; the silk put into it, and boiled for two hours. After the bath has cooled, the silk is usually allowed to remain in it for three hours longer.

443 Poppy

The colours known by the names of poppy, cherry, rose, and flesh-colour, are given to silk by means of carthamus. The process consists merely in keeping the silk, as long as it extracts any colour, in an alkaline solution of carthamus, into which as much lemon juice as gives it a fine cherry colour has been poured. To produce a deep poppy red, the silk must be put successively into a number of similar baths, and allowed to drain them. When the silk is dyed, the colour is brightened by plunging it into hot water acidulated with lemon juice. The silk ought to be previously dyed yellow with anotta.

444 Cherry

Cherry red is produced the same way, only the anotta ground is omitted, and less colouring matter is necessary. When a flesh colour is required, a little soap should be put into the bath, which softens the colour, and prevents it from taking too quickly. 445 Flesh red

To lessen the expense, some archil is often mixed with carthamus for dark shades.

The same shades may be dyed by means of brazil wood, but they do not stand.

446 Scarlet

Silk cannot be dyed a full scarlet; but a colour approaching to scarlet may be given it, by first impregnating the stuff with murio-sulphat of tin, and afterwards dyeing it in a bath composed of four parts of cochineal and four parts of quercitron bark. To give the colour more body, both the mordant and the dye may be repeated.* A colour approaching scarlet may be also given to silk, by first dyeing it crimson, then dyeing it with *carthamus*, and lastly yellow without heat.†

* *Bancr.* i. 312.

† *Berth.* ii. 203.

447 How to dye cotton and linen red

10. Cotton and linen are dyed red with madder. The process was borrowed from the East; hence the colour is often called *Adrianople* or *Turkey red*. The cloth is first impregnated with oil, then with galls, and lastly with alum, in the manner described in the last section. It is then boiled for an hour in a decoction of madder, which is commonly mixed with a quantity of blood. After the cloth is dyed, it is plunged into a soda ley, in order to brighten the colour. The red given by this process is very permanent, and when properly conducted it is exceedingly beautiful. The whole difficulty consists in the application of the mordant, which is by far the most complicated employed in the whole art of dyeing.

Cotton may be dyed scarlet by means of murio-sulphat of tin, cochineal, and quercitron bark, used as for silk; but the colour is too fading to be of any value.*

* *Bancr.* i. 316.

SECT. IV. *Of Black.*

448 Black d

1. THE substances employed to give a black colour to cloth are red oxyd of iron and tan. These two substances

lack. ſtances have a ſtrong affinity for each other; and when combined, aſſume a deep black colour, not liable to be deſtroyed by the action of air and light. The affinity which each of them has for the different kinds of cloth has been already mentioned.

2. Logwood is uſually employed as an auxiliary, becauſe it communicates luſtre, and adds conſiderably to the fullneſs of the black. It is the wood of the tree called by Linnæus *hæmatoxylum campechianum*, which is a native of ſeveral of the Weſt India iſlands, and of that part of Mexico which ſurrounds the Bay of Honduras. It yields its colouring matter to water. The decoction is at firſt a fine red bordering on violet, but if left to itſelf it gradually aſſumes a black colour. Acids give it a deep red colour; alkalies a deep violet, inclining to brown. Sulphat of iron renders it as black as ink, and occaſions a precipitate of the ſame colour. The precipitate produced by alum is dark red; the ſupernatent liquid becomes yellowiſh red.* *rtholl**et,*

55. 3. Cloth, before it receives a black colour, is uſually dyed blue. This renders the colour much fuller and finer than it otherwiſe would be. If the cloth be coarſe, the blue dye may be too expenſive; in that caſe a brown colour is given by means of walnut peels.

149 to in- a on 4. Wool is dyed black by the following proceſs. It is boiled for two hours in a decoction of nut galls, and afterwards kept for two hours more in a bath compoſed of logwood and ſulphat of iron, kept during the whole time at a ſcalding heat, but not boiled. During the operation it muſt be frequently expoſed to the air; becauſe the green oxyd of iron, of which the ſulphat is compoſed muſt be converted into red oxyd by abſorbing oxygen, before the cloth can acquire a proper colour. The common proportions are five parts of galls, five of ſulphat of iron, and 30 of logwood for every 100 of cloth. A little acetite of copper is commonly added to the ſulphat of iron, becauſe it is thought to improve the colour.

5● ilk, 5. Silk is dyed nearly in the ſame manner. It is capable of combining with a very great deal of tan; the quantity given is varied at the pleaſure of the artiſt, by allowing the ſilk to remain a longer or ſhorter time in the decoction. After the galling, the ſilk is put into a ſolution of ſulphat of iron which is uſually mixed with a certain quantity of iron filings and of gum. It is occaſionally wrung out of the bath, expoſed for ſome time to the air, and again immerſed. When it has acquired a ſufficiently full colour, it is waſhed in cold water, and afterwards ſteeped in a decoction of ſoap to take off the harſhneſs, which ſilk always has after being dyed black.

51 n, and on. 6. It is by no means ſo eaſy to give a full black to linen and cotton. The cloth, previouſly dyed blue, is ſteeped for 24 hours in a decoction of nut galls. A bath is prepared, containing acetite of iron, formed by ſaturating acetous acid with brown oxyd of iron. Into this bath the cloth is put in ſmall quantities at a time, wrought with the hand for a quarter of an hour, then wrung out and aired, again wrought in a freſh quantity of the bath, and afterwards aired. Theſe alternate proceſſes are repeated till the colour wanted is given. A decoction of alder bark is uſually mixed with the liquor containing the nut galls.

It would probably contribute to the goodneſs and permanence of the colour, if the cloth, before being galled, were impregnated with oil, by being ſteeped in a mixture of alkaline ley and oil combined as is practiſed for dyeing cotton red. Brown.

SECT. V. *Of Brown.*

THAT particular *brown* colour, with a caſt of *yellow*, which the French call *fauve*, and to which the Engliſh writers on *dyeing* have appropriated the word *fawn*, though in fact a compound, is commonly ranked among ſimple colours; becauſe it is applied to cloth by a ſingle proceſs. The ſubſtances employed to produce this colour are numerous; but we ſhall ſatisfy ourſelves with enumerating the following: 452

Walnut-peels are the green covering of the walnut. When firſt ſeparated, they are white internally; but ſoon aſſume a brown, or even a black colour, on expoſure to the air. They readily yield their colouring matter to water. They are uſually kept in large caſks, covered with water, for above a year, before they are uſed. To dye wool brown with them, nothing more is neceſſary than to ſteep the cloth in a decoction of them till it has acquired the wiſhed-for colour. The depth of the ſhade is proportional to the ſtrength of the decoction. The root, as well as the peel of the walnut tree, contains the ſame colouring matter, but in ſmaller quantity. The bark of the birch, alſo, and many other trees, may be uſed for the ſame purpoſe. Brown dyes.

It is very probable, that the brown colouring matter is in theſe vegetable ſubſtances combined with tan. This is certainly the caſe in ſumach, which is often employed to produce a brown. This combination explains the reaſon why no mordant is neceſſary; the tan has a ſtrong affinity for the cloth, and the colouring matter for the tan. The dye ſtuff and the mordant are already in fact combined together.

CHAP. V. OF COMPOUND COLOURS.

COMPOUND colours are produced by mixing together two ſimple ones; or, which is the ſame thing, by dyeing cloth firſt one ſimple colour, and then another. The reſult is a compound colour, varying in ſhade according to the proportions of each of the ſimple colours employed. 453

Compound colours are exceedingly numerous, varying almoſt to infinity, according to the proportions of the ingredients employed. They may be all arranged under the following claſſes: Diviſion of compound colours.

Mixtures of 1. blue and yellow,
2. blue and red,
3. yellow and red,
4. black and other colours.

To deſcribe all the different ſhades which belong to each of theſe claſſes, would be impoſſible; and even if it were poſſible, it would be unneceſſary; becauſe all the proceſſes depend upon the principles laid down in the preceding chapters, and may eaſily be conceived and varied by thoſe who underſtand theſe principles. In the following ſections, therefore, it will be ſufficient to mention the principal compound colours produced by the mixture of ſimple colours, and to exhibit a ſpecimen or two of the mode of producing them.

SECT. I. *Of Mixtures of Blue and Yellow.*

THE colour produced by mixtures of blue and yellow

Mixtures of Blue and Yellow. is *green*; which is distinguished by dyers by a great variety of names, according to the depth of the shade, or the prevalence of either of the component parts. Thus we have *sea green*, *meadow* or *grass green*, *pea green*, &c. &c.

454 How to induce green

455 On wool, Wool is usually dyed green by giving it first a blue colour, and afterwards dyeing it yellow; because, when the yellow is first given, several inconveniences follow; the yellow partly separates again in the blue vat, and communicates a green colour to it; and thus renders it useless for every other purpose, except dyeing green. Any of the processes for dyeing blue, described in the last chapter may be followed; care being taken always to proportion the depth of the blue to the shade of the green which is required. The cloth thus dyed blue may receive a yellow colour, by following the processes described in the last chapter for that purpose. When the sulphat of indigo is employed, it is usual to mix all the ingredients together, and to dye the cloth at once; the colour produced is known by the name of *Saxon*, or *English green*. One of the most convenient methods of conducting this process is the following.

Six or eight parts of quercitron bark, tied up in a bag, are to be put into the dyeing vessel, which should contain only a small quantity of warm water. When the water boils, six parts of murio-sulphat of tin, and four parts of alum, are to be added. In a few minutes the dyeing vessel should be filled up with cold water, till the temperature is reduced to about 130°. After this as much sulphat of indigo is to be poured in as is sufficient to produce the intended shade of green. When the whole has been sufficiently stirred, a hundred parts of cloth are to be put in, and turned briskly for about fifteen minutes, till it has acquired the wished-for shade.* By this method, a much more beautiful colour is obtained than is given by the usual process, in which fustic is employed to give the yellow shade.

* *Bancroft*, i. 336.

456 Silk, Silk, intended to receive a green colour, is usually dyed yellow first by means of weld, according to the process described in the last chapter; afterwards, it is dipped into the blue vat, and dyed in the usual manner. To deepen the shade, or to vary the tint, decoctions of logwood, anotta, fustic, &c. are added to the yellow bath. Or silk may be dyed at once green, by adding suitable proportions of sulphat of indigo to the common quercitron bark bath, composed of four parts of bark, three parts of alum and two parts of murio-sulphat of tin.†

† *Ibid.* 346.

457 Cotton, and linen. Cotton and linen must be first dyed blue, and then yellow according to the methods described in the last chapter. It is needless to add, that the depth of each of these colours must be proportioned to the shade of green colour which it is the intention of the dyer to give.

SECT. II. *Of Mixtures of Blue and Red.*

458 Violet, purple, lilac. The mixture of blue and red produces *violet*, *purple*, and *lilac*, of various shades, and known by various names, according to the proportion of the ingredients employed. When the colour is deep, and inclines most to blue, it is called *violet*; but when the red is prevalent, it gets the name of *purple*. When the shade is light, the colour is usually called *lilac*. For violet, therefore, the cloth must receive a deeper blue; for purple, a deeper red? and for lilac, both of these colours must be light.

459 How induced on wool, Wool is usually dyed first *blue*; the shade, even for violet, ought not to be deeper than that called *sky blue*; afterwards it is dyed scarlet, in the usual manner. The violets and purples are dyed first; and when the vat is somewhat exhausted, the cloth is dipped in which is to receive the lilac, and the other lighter shades. By means of sulphat of indigo, the whole process may be performed at once. The cloth is first alumed, and then dyed in a vessel, containing cochineal, tartar, and sulphat of indigo, in proportions suited to the depth of the colour required.* A violet colour may also be given to wool, by impregnating it with a mordant composed of tin dissolved in a mixture of sulphuric and muriatic acids, formed by dissolving muriat of soda in sulphuric acid: to which solution a quantity of tartar and sulphat of copper is added. The wool is then boiled in a decoction of logwood till it has acquired the wished-for colour.†

* *Poern*

† *Decroizille, Berthollet*, ii. 331.

460 Silk Silk is first dyed crimson, by means of cochineal, in the usual way, excepting only that no tartar, nor solution of tin is employed; It is then dipped into the indigo vat till it has acquired the wished-for shade. The cloth is often afterwards passed through an archil bath which greatly improves the beauty of the colour. Archil is often employed as a substitute for cochineal: The silk first receives a red colour, in the usual way, by being dyed in an archil bath; afterwards it receives the proper shade of blue. The violet, or purple, given by this process is very beautiful, but not very lasting.‡

‡ *Berth.* ii. 327.

Silk may be dyed violet or purple at once. by first treating it with a mordant, composed of equal parts of nitro-muriat of tin and alum, and then dipping it into a cochineal bath into which a proper quantity of sulphat of indigo has been poured. But this dye is fading; the blue colour soon decays, and the silk becomes red.*

* *Gubli Bertholl.* ii. 329

461 Cotton, and linen Cotton and linen are first dyed blue, then galled, then soaked in a decoction of logwood; some alum and acetite of copper are added to the decoction, and the cloth is soaked again. This process is repeated till the proper colour is obtained.† The colour produced by this method is not nearly equal in permanency to that described in this *Supplement* under the word Iron; to which we beg leave to refer the reader. The process there described has been long known; but Mr Chaptal has simplified it somewhat.

† *Berth.* ii. 337

Sect. III. *Of Mixtures of Yellow and Red.*

462 Orange and olive The colour produced by the mixture of *red* and *yellow* is *orange*; but almost an infinity of shades results from the different proportions of the ingredients, and from the peculiar nature of the yellow employed. Sometimes *blue* is combined with red and yellow on cloth; the resulting colour is called *olive*.

463 How induced on wool, Wool may be dyed orange by precisely the same process which is used for scarlet, only the proportion of red must be diminished, and that of yellow increased. When wool is first dyed red with madder, and then yellow with weld, the resulting colour is called *cinnamon colour*. The mordant, in this case, is a mixture of alum and tartar. The shade may be varied exceedingly, by using other yellow dye stuffs instead of weld, and by varying the proportions, according to circumstances. Thus a reddish yellow may be given to cloth, by first dyeing it yellow, and then passing it through a madder bath.

464 Silk Silk is dyed orange by means of carthamus: the method

...tures Black other ...ours. method has been deſcribed in the laſt chapter. Cinnamon colour is given to it by dyeing it, previouſly alumed, in a bath compoſed of the decoctions of logwood, Brazil wood, and fuſtic mixed together.

465 ...on, linen. Cotton and linen receive a cinnamon colour by means of weld and madder. The proceſs is complicated. The cloth is firſt dyed with weld and acetite of copper, then dipped in a ſolution of ſulphat of iron, then galled, then alumed, and then dyed in the uſual way with madder.*

...rthollet, 44. For *olive*, the cloth is firſt dyed blue, then yellow, and laſtly paſſed through a madder bath. The ſhade depends upon the proportion of each of theſe colours. For very deep ſhades the cloth is alſo dipped into a ſolution of ſulphat of iron. Cotton and linen may be dyed *olive* by dipping them into a bath, compoſed of the decoction of four parts of weld and one of potaſs, mixed with the decoction of Brazil wood and a little acetite of copper.† Aplig-bid.

SECT. IV. *Of Mixtures of BLACK with other Colours.*

466 ...rs, ..., and ...rs. STRICTLY ſpeaking, the mixtures belonging to this ſection are not mixtures of *black colours* with other colours, but combinations of the *black dye* with other colours; the ingredients of which, galls and brown oxyd of iron, being both mordants, variouſly modify other colouring matters by combining with them. Thus if cloth be previouſly combined with brown oxyd of iron, and afterwards dyed yellow with quercitron bark, the reſult will be a *drab* of different ſhades, according to the proportion of mordant employed. When the proportion is ſmall, the colour inclines to olive or yellow; on the contrary, the drab may be deepened or ſaddened, as the dyers ſpeak, by mixing a little ſumach with the bark.* The precautions formerly mentioned in applying the oxyd muſt be obſerved. ...ncroft, 3.

It is very common to dip cloth already dyed ſome particular colour into a ſolution of ſulphat of iron, and galls or ſome other ſubſtance containing tan, called the *black bath*, in order to alter the ſhade, and to give the colour greater permanency. We ſhall give a few inſtances: greater minuteneſs would be inconſiſtent with the nature of this article.

Cloth dyed blue, by being dipped into the *black* bath, becomes *bluiſh grey*. Cloth dyed *yellow*, by the ſame proceſs, becoms *blackiſh grey*, *drab*, or *yellowiſh brown*. Cloth previouſly alumed, and dyed in a decoction of cochineal and acetite of iron, acquires a permanent *violet colour* inclining to *brown*, or a *lilac*, if the dyeing veſſel be ſomewhat exhauſted.* Cloth ſteeped in a mordant, compoſed of alum and acetite of iron diſſolved in water, and afterwards dyed in a bath compoſed of the decoction of galls and madder mixed together, acquires a fine deep *brown*. The method of varying the ſhades of linen and cotton will be readily conceived, after we have given an account of calico printing, which forms the ſubject of the next chapter. ...llicbe, bollet, 49.

CHAP. VI. OF CALICO PRINTING.

CALICO printing is the art of communicating different colours to particular ſpots or figures on the ſurface of cotton or linen cloth, while the reſt of the ſtuff retains its original whiteneſs.

Calico Printing. 467 Origin of calico printing.

This ingenious art ſeems to have originated in India, where we know it has been practiſed for more than 2000 years. Pliny indeed informs us, that the Egyptians were acquainted with calico printing; but a variety of circumſtances combine to render it more than probable that they borrowed it from India. The art has but lately been cultivated in Europe; but the enlightened induſtry of our manufacturers has already improved prodigiouſly upon the tedious proceſſes of their Indian maſters. No art has riſen to perfection with greater celerity: a hundred years ago it was ſcarcely known in Europe; at preſent, the elegance of the patterns, the beauty and permanency of the colours, and the expedition with which the different operations are carried on, are really admirable.

A minute detail of the proceſſes of calico printing would not only be foreign to the plan of this article, but of very little utility. To the artiſt the proceſſes are already known; an account of them therefore could give him no new information; while it would fatigue and diſappoint thoſe readers who wiſh to underſtand the principles of the art. We ſhall content ourſelves, therefore, with a ſhort view of theſe principles.

468 It conſiſts in applying mordants partially to cotton.

Calico printing conſiſts in impregnating thoſe parts of the cloth which are to receive a colour with a mordant, and then dyeing it as uſual with ſome dye ſtuff or other. The dye ſtuff attaches itſelf firmly only to that part of the cloth which has received the mordant. The whole ſurface of the cotton is indeed more or leſs tinged; but by waſhing it, and bleaching it for ſome days on the graſs with the wrong ſide uppermoſt, all the unmordanted parts reſume their original colour, while thoſe which have received the mordant retain it. Let us ſuppoſe, that a piece of white cotton cloth is to receive red ſtripes; all the parts where the ſtripes are to appear are penciled over with a ſolution of acetite of alumina. After this, the cloth is dyed in the uſual manner with madder. When taken out of the dyeing veſſel, it is all of a red colour; but by waſhing and bleaching, the madder leaves every part of the cloth white except the ſtripes impregnated with the acetite of alumina, which remain red. In the ſame manner, may yellow ſtripes, or any other wiſhed-for figure, be given to cloth, by ſubſtituting quercitron bark, weld, &c. for madder. 469 Which is afterwards dyed and bleached.

When different colours are to be given to different parts of the cloth at the ſame time, it is done by impregnating it with various mordants. Thus if ſtripes be drawn upon a cotton cloth with acetite of alumina, and other ſtripes with acetite of iron, and the cloth be afterwards dyed in the uſual way with madder and then waſhed and bleached, it will be ſtriped *red* and *brown*. The ſame mordants with quercitron bark give *yellow*, and *olive* or *drab*.

470 Mordants employed.

The mordants employed in calico printing are acetite of alumina and acetite of iron, prepared in the manner deſcribed in the third chapter of this part. Theſe mordants are applied to the cloth, either with a pencil or by means of blocks, on which the pattern, according to which the cotton is to be printed, is cut. As they are applied only to particular parts of the cloth, care muſt be taken that none of them ſpread to the part of the cloth which is to be left white, and that they do not interfere with one another when more than one are applied.

Calico Printing. applied. If these precautions be not attended to, all the elegance and beauty of the print must be destroyed. It is necessary, therefore, that the mordants should be of such a degree of consistence that they will not spread beyond those parts of the cloth on which they are applied. This is done by thickening them with flour or starch when they are to be applied by the block, and with gum arabic when they are to be put on with a pencil. The thickening should never be greater than is sufficient to prevent the spreading of the mordants; when carried too far, the cotton is apt not to be sufficiently saturated with the mordant; of course the dye takes but imperfectly.

471 How applied. In order that the parts of the cloth impregnated with mordants may be distinguished by their colour, it is usual to tinge the mordants with some colouring matter or other. The printers commonly use the decoction of Brazil wood for this purpose; but Bancroft has objected to this method, because he thinks that the Brazil wood colouring matter impedes the subsequent process of dyeing. It is certain, that the colouring matter of the Brazil wood is displaced during that operation by the superior affinity of the dye stuff for the mordant. Were it not for this superior affinity, the colour would not take at all. Dr Bancroft* advises to colour the mordant with some of the dye stuff afterwards to be applied; and he cautions the using of more for that purpose than is sufficient to make the mordant distinguishable when applied to the cloth. The reason of this precaution is obvious. If too much dye be mixed with the mordant, a great proportion of the mordant will be combined with colouring matter; which must weaken its affinity for the cloth, and of course prevent it from combining with it in sufficient quantity to ensure a permanent dye.

* *Bancroft*, i. 373.

Sometimes these two mordants are mixed together in different proportions; and sometimes one or both is mixed with an infusion of sumach or of nut galls. By these contrivances, a great variety of colours are produced by the same dye stuff.

472 Subsequent treatment of the cloth. After the mordants have been applied, the cloth must be completely dried. It is proper for this purpose to employ artificial heat; which will contribute something towards the separation of the acetous acid from its base, and towards its evaporation; by which the mordant will combine in a greater proportion, and more intimately with the cloth.

When the cloth is sufficiently dried, it is to be washed with warm water and cow dung, till all the flour or gum employed to thicken the mordants, and all those parts of the mordants which are uncombined with the cloth, are removed. The cow dung serves to entangle these loose particles of mordants, and to prevent them from combining with those parts of the cloth which are to remain white. After this the cloth is thoroughly rinsed in clean water.

473 Dye stuffs used. Almost the only dye stuffs employed by calico printers are, indigo, madder, and quercitron bark or weld. This last substance, however, is now but little used by the printers of this country, except for delicate greenish yellows. The quercitron bark has almost superseded it; because it gives colours equally good, and is much cheaper, and more convenient, not requiring so great a heat to fix it. Indigo, not requiring any mordant, is commonly applied at once either with the block or a pencil. It is prepared by boiling together indigo, potass made caustic by quicklime, and orpiment: the solution is afterwards thickened with gum (K). It must be carefully secluded from the air, otherwise the indigo would soon be regenerated, which would render the solution useless. Dr Bancroft has proposed to substitute coarse brown sugar for orpiment. It is equally efficacious in decomposing the indigo and rendering it soluble; while it likewise serves all the purposes of gum.*

* *Bancroft*, i. 120.

When the cloth, after being impregnated with the mordant, is sufficiently cleansed, it is dyed in the usual manner. The whole of it is more or less tinged with the dye stuff. It is well washed, and then spread out for some days on the grass, and bleached with the wrong side uppermost. This carries the colour off completely from all the parts of the cotton which have not imbibed the mordant, and leaves them of their original whiteness, while the mordanted spots retain the dye as strongly as ever.

Let us now give an example or two of the manner in which the printers give particular colours to calicoes. Some calicoes are only printed of one colour, others have two, others three, or more, even to the number of eight, ten, or twelve. The smaller the number of colours, the fewer in general are the processes.

47[4] Method of printing drabs, 1. One of the most common colours on cotton prints is a kind of nankeen yellow, of various shades, down to a deep yellowish brown or drab. It is usually in stripes or spots. To produce it, the printers besmear a block, cut out into the figure of the print, with acetite of iron thickened with gum or flour; apply it to the cotton; which, after being dried and cleaned in the usual manner, is

(K) Different proportions are used by different persons. Mr Hauffman mixes 25 gallons of water with 16 pounds of indigo well ground (or a greater or smaller quantity, according to the quality of the indigo and the depth of colour wanted); to which he adds 30 pounds of good carbonat of potass, placing the whole over a fire; and as soon as the mixture begins to boil, he adds, by a little at a time, 12 pounds of quick lime, to render the alkali caustic, by absorbing its carbonic acid. This being done, 12 pounds of red orpiment are also added to the mixture; which is then stirred, and left to boil for some little time, that the indigo may be perfectly dissolved; which may be known by its giving a yellow colour immediately upon being applied to a piece of white transparent glass. M. Oberkampf, proprietor of the celebrated manufactory at Jouy near Versailles, uses a third more of indigo; and others use different proportions, not only of indigo, but of lime, potass, and orpiment; which all seem to answer with nearly equal success: but with the best copper-coloured Guatamala indigo, it is certain that a good blue may be obtained from only half the quantity prescribed by Mr Hauffman, by using as much stone, or oyster shell lime, as of indigo, nearly twice as much potass, and a fourth part less of orpiment than of indigo. See *Bancroft*, I. 113.

lico ting. is plunged into a potafs ley. The quantity of acetite of iron is always proportioned to the depth of the intended fhade.

75 ow, 2. For yellow, the block is befmeared with acetite of alumina. The cloth, after receiving this mordant, is dyed with quercitron bark, and then bleached.

76 :d, 3. Red is communicated by the fame procefs, only madder is fubftituted for the bark.

77 ee, 4. The fine light blues, which appear fo often on printed cottons, are produced, by applying to the cloth a block befmeared with a compofition, confifting partly of wax, which covers all thofe parts of the cloth which are to remain white. The cloth is then dyed in a cold indigo vat; and after it is dry, the wax compofition is removed by means of hot water.

78 1, 5. Lilac, flea brown, and blackifh brown, are given by means of acetite of iron; the quantity of which is always proportioned to the depth of the fhade. For very deep colours, a little fumach is added. The cotton is afterwards dyed in the ufual manner with madder, and then bleached.

79 love. 6. Dove colour and drab, by acetite of iron and quercitron bark.

80 ca- f dif- co- o the cloth. When different colours are to appear in the fame print, a greater number of operations are neceffary. Two or more blocks are employed, upon each of which that part of the print only is cut which is to be of fome particular colour. Thefe are befmeared with different mordants, and applied to the cloth, which is afterwards dyed as ufual. Let us fuppofe, for inftance, that three blocks are applied to cotton; one with acetite of alumina, another with acetite of iron, a third with a mixture of thefe two mordants, and that the cotton is then dyed with quercitron bark, and bleached. The parts impregnated with the mordants would have the following colours.

Acetite of alumina, - -	Yellow,
iron, - - -	Olive, drab, dove (L),
The mixture, - - - -	Olive green, olive.

If part of the yellow be covered over with the indigo liquor, applied with a pencil, it will be converted into *green:* By the fame liquid, blue may be given to fuch parts of the print as require it.

If the cotton be dyed with madder inftead of quercitron bark, the print will exhibit the following colours:

Acetite of alumina, - - -	Red,
iron, - - - -	Brown, black,
The mixture, - - - - -	Purple.

When a greater number of colours are to appear; for inftance, when thofe communicated by bark and thofe by madder are wanted at the fame time, mordants for part of the pattern are to be applied; the cotton is then to be dyed in the madder bath and bleached; then the reft of the mordants, to fill up the pattern, are added, and the cloth is again dyed with quercitron bark and bleached. This fecond dyeing does not much affect the madder colours; becaufe the mordants, which render them permanent, are already faturated. The yellow tinge is eafily removed by the fubfequent bleaching. Sometimes a new mordant is alfo applied to fome of the madder colours; in confequence of which they receive a new permanent colour from the bark. After the laft bleaching, new colours may be added by means of the indigo liquor. The following table will give an idea of the colours which may be given to cotton by thefe complicated proceffes. Calico Printing.

I. *Madder dye.*	*Colours.*
Acetite of alumina, - - -	Red,
iron, - - - -	Brown, black,
Ditto diluted, - - - - -	Lilac,
Both mixed, - - - - -	Purple.
II. *Bark dye.*	
Acetite of alumina, - - -	Yellow,
iron, - - - -	Dove, drab,
Lilac and acetite of alumina,	Olive,
Red and acetite of alumina,	Orange.
III. *Indigo dye.*	
Indigo, - - - - - - - -	Blue,
Indigo and yellow - - -	Green.

Thus no lefs than 12 colours may be made to appear together in the fame print by thefe different proceffes.

Thefe inftances will ferve to give the reader an idea of the nature of calico printing, and at the fame time afford an excellent illuftration of the importance of mordants in dyeing.

If it were poffible to procure colours fufficiently permanent, by applying them at once to the cloth by the block or the pencil, as is the cafe with the mordants, the art of calico printing would be brought to the greateft poffible fimplicity: but at prefent this can only be done in one cafe, that of indigo; every other colour requires dyeing. Compofitions indeed may be made by previoufly combining the dye ftuff and the mordants. Thus *yellow* may be applied at once by employing a mixture of the infufion of quercitron bark and acetite of alumina; *red*, by mixing the fame mordant with the decoction of alumina, and fo on. Unfortunately the colours applied in this way are far inferior in permanency to thofe produced when the mordant is previoufly combined with the cloth, and the dye ftuff afterwards applied feparately. In this way are applied almoft all the fugitive colours of calicoes which wafhing or even expofure to the air deftroys. 481 Colours for pencilling.

As the application of colours in this way cannot always be avoided by calico printers, every method of rendering them more permanent is an object of importance. We fhall therefore conclude this chapter with a defcription of feveral colours of this kind propofed by Dr Bancroft, which have a confiderable degree of permanence.

A *yellow* printing colour may be formed by the following method: Let three pounds of alum, and three ounces of clean chalk, be firft diffolved in a gallon of hot water, and then add two pounds of fugar of lead; ftir this mixture occafionally during the fpace of 24 or 36 hours, then let it remain 12 hours at reft, and afterwards decant and preferve the clear liquor; this being

(L) According to the proportion of acetite of iron employed.

Calico Printing.

ing done, pour ſo much more warm water upon the remaining ſediment, as after ſtirring and leaving the mixture to ſettle will afford clear liquor enough to make, when mixed with the former, three quarts of this aluminous mordant or acetite of alumine. Then take not leſs than ſix, nor more than eight, pounds of quercitron bark properly ground; put this into a tinned copper veſſel, with four or five gallons of clean ſoft water, and make it boil for the ſpace of one hour at leaſt, adding a little more water, if at any time the quantity of liquor ſhould not be ſufficient to cover the ſurface of the bark: the liquor having boiled ſufficiently, ſhould be taken from the fire, and left undiſturbed for half an hour, and then the clear decoction ſhould be poured off through a fine ſieve or canvas ſtrainer. This being done, let ſix quarts more of clear water be poured upon the ſame bark, and made to boil ten or fifteen minutes, both having been firſt well ſtirred; and being afterwards left a ſufficient time to ſettle, the clean decoction may then be ſtrained off, and put with the former into a ſhallow wide veſſel to be evaporated by boiling, until what remains, being joined to the three quarts of aluminous mordant before mentioned, and to a ſufficient quantity of gum or paſte for thickening, will barely ſuffice to make three gallons of liquor in the whole. It will be proper, however, not to add the aluminous mordant, until the decoction is ſo far cooled as to be but little more than blood warm; and theſe being thoroughly mixed by ſtirring, may afterwards be thickened by the gum of Senegal or by gum arabic, if the mixture is intended for penciling; or by a paſte made with ſtarch or flour, if it be intended for printing.

Calico Printing.

By ſubſtituting a pound of murio-ſulphat of tin for the aluminous mordant in the above compoſition, a mixture may be formed which affords a very bright and full yellow, of conſiderable durability.

Sulphat of tin, mixed with a decoction of quercitron bark, communicates to cotton a *cinnamon* colour, which is ſufficiently permanent.*

When the decoctions of quercitron bark and logwood are boiled together, and ſuitable proportions of ſulphat of copper and of verdigris are added to them, with a little carbonat of potaſs, a compound is formed, which gives a *green* colour to cotton. Bancroft has made trial of this; and though it has not fully anſwered his expectation, his attempts were attended with ſufficient ſucceſs to determine him to perſevere in his experiments.†

* *Bancroft* i. 400.

† *Ibid.*

If acetite of iron be mixed with a decoction of quercitron bark, and the mixture be properly thickened, the compound will communicate to cotton a *drab* colour of ſome durability. This compound, mixed with the olive colouring liquor above deſcribed, will produce an olive. If a ſolution of iron, by a diluted muriatic acid, or by a diluted nitric acid, be employed for this purpoſe inſtead of iron liquor, it will produce colours a little more laſting; but theſe ſolutions ſhould be employed ſparingly, that they may not hurt the texture of the linen or cotton to which they are intended to be applied.

Subtriple || Sudbury.

SUBTRIPLE, is when one quantity is the 3d part of another; as 2 is ſubtriple of 6. And *Subtriple Ratio* is the ratio of 1 to 3.

SUBTRIPLICATE RATIO, is the ratio of the cube roots. So the ſubtriplicate ratio of a to b, is the ratio of $\sqrt[3]{a}$ to $\sqrt[3]{b}$, or of $a^{\frac{1}{3}}$ to $b^{\frac{1}{3}}$.

SUCCESS, a bay, alſo called *Good Succeſs*, on Terra del Fuego, or the weſtern ſhore of Strait le Maire. S. lat. 54 50, W. long. 65 25. Cape Succeſs, on the point of this bay, lies in lat. 55 1 S. and long. 65 27 W.—*Morse.*

SUCCESS, a townſhip of New-Hampſhire, in Grafton county, N. E. of the White Mountains on the eaſt line of the State, incorporated in 1773.—*ib.*

SUCCESSION OF SIGNS, in aſtronomy, is the order in which they are reckoned, or follow one another, and according to which the ſun enters them; called alſo *conſequentia*. As Aries, Taurus, Gemini, Cancer, &c.

SUCK *Creek* empties into Tenneſſee river from the ſouth-ſouth-eaſt, at the *Suck* or *Whirl*, where the river is contracted to the breadth of 70 yards. It is a few miles north from the Georgia north line.—*Morse.*

SUCKLING *Cape*, on the N. W. part of N. America; off which, and to the N. E. end of Kaye's Iſland, is a muddy bottom with from 43 to 27 fathoms water. The ſouth-weſt point of Kaye's Iſland is in lat. 59 49 N. and long. 143 2 W.—*ib.*

SUFFIELD, a pleaſant poſt-town of Connecticut, Hartford county, having a handſome church and ſome reſpectable dwelling houſes. It is on the weſt bank of Connecticut river on the great poſt-road from Boſton to New-York, 10 miles ſouth of Springfield, 17 N. of Hartford, and 232 N. E. of Philadelphia. This townſhip was purchaſed of two Indian ſachems for £30, and in 1670, was granted to Major John Pyncheon, by the aſſembly of Maſſachuſetts.—*ib.*

SUFFOLK, a county of Maſſachuſetts, ſo named from that in England, in which governor Winthrop lived, before he emigrated to America. It contained in 1790, 23 townſhips, 6,335 houſes, 13,038 families, 44,875 inhabitants. In 1793, the county was divided; and now the new county, Norfolk, comprehends all the towns except Boſton, Chelſea, Hull, and Hingham. Suffolk was conſtituted a county, May 10, 1643.—*ib.*

Suffolk, a county of New-York, L. Iſland, is about 100 miles long, and 10 broad, and comprehends all that part of the State bounded eaſterly and ſoutherly by the Atlantic Ocean, northerly by the Sound, and weſterly by Lloyd's Neck, or Queen's Village, Cold Spring harbour, and the eaſt bounds of the townſhip of Oyſter Bay; the line continued ſouth to the Atlantic Ocean, including the Iſle of Wight, now called Gardner's Iſland, Shelter Iſland, Plumb Iſlands, Robin's Iſland, and the Gull Iſlands. Fiſher's Iſland alſo belongs to it. It contains 16,440 inhabitants, of whom 1,098 are ſlaves. There are 9 townſhips, and 2,609 of the inhabitants are electors. Suffolk county court-houſe, is 15 miles from Southampton, 27 from Sagg Harbour, and 80 from New-York city.—*ib.*

Suffolk, a poſt-town of Virginia, in Nanſemond county, on the eaſt ſide of the river Nanſemond. It contains a court-houſe, gaol, and about 40 houſes. The river is thus far navigable for veſſels of 250 tons. It is 28 miles weſt by ſouth of Portſmouth, 83 E. S. E. of Peterſburg, 110 ſouth-eaſt of Richmond, and 386 from Philadelphia.—*ib.*

SUFFRAGE, a townſhip of New-York, ſituated in Otſego county, on the north ſide of Suſquehannah river; taken from Unadilla, and incorporated in 1796. —*ib.*

SUGAR *Creek*, or *Cæſar's Creek*, a conſiderable branch of Little Miami river.—*ib.*

Sugar *Hill*, a ragged eminence the top of which overlooks and commands the whole works of Ticonderoga, where the waters of Lake George empty into Lake Champlain, and oppoſite to Fort Independence, in the State of Vermont. Gen. Burgoyne made a lodgement on this hill, which the Americans eſteemed inacceſſible; and thus forced Gen. St Clair to abandon the fort in June, 1777.—*ib.*

Sugar *River*, in Cheſhire county, New-Hampſhire, riſes in Sunapee lake, and, after a ſhort courſe weſterly, empties into Connecticut river, at Clermont, and oppoſite to Aſhcutney mountain in Vermont. There is a ſtrong expectation of uniting this river, by a ſhort canal, with Contocook, which falls into Merrimack river at Boſcawen.—*ib.*

Sugar-Loaf *Bay*, on the north-eaſt ſide of Juan Fernandes Iſland; 100 leagues to the weſt of the coaſt of Chili.—*ib.*

Sugar, a river of Veragua, which empties into the Bay of Honduras.—*ib.*

SULLIVAN, a townſhip of Cheſhire county, New-Hampſhire, containing 220 inhabitants.—*ib.*

Sullivan, a poſt-town of the Diſtrict of Maine, Hancock county, and on Frenchman's Bay, 12 miles north-weſt of Goldſborough, 38 W. S. W. of Penobſcot, 310 north-eaſt of Boſton, and 645 north-eaſt of Philadelphia. The townſhip contains 504 inhabitants. —*ib.*

Sullivan, a county of Tenneſſee, in Waſhington diſtrict. In 1795, it contained according to the State cenſus, 8,457 inhabitants, of whom 777 were ſlaves. —*ib.*

Sullivan's *Iſland*, one of the three iſlands which form the north part of Charleſton harbour, in S. Carolina. It is about 7 miles ſouth-eaſt of Charleſton.—*ib.*

SULPHUR *Creek, Little*, one of the ſouthern upper branches of Green river in Kentucky; and lies ſouth-weſt of another branch called Bryant's Lick creek. Near this is a ſulphur ſpring.—*ib.*

Sulphur *Mountain*, a noted mountain in the iſland of Guadaloupe, famous for exhalations of ſulphur, and eruptions of aſhes. On the E. ſide are two mouths of an enormous ſulphur pit; one of theſe mouths is 100 feet in diameter; the depth is unknown.—*ib.*

SULPHURET of lime having lately been recommended by an eminent chemiſt* as a ſubſtitute for *potaſh* in the new method of bleaching, which, if it anſwer, may certainly be afforded at leſs expenſe, we ſhall here give the method of preparing the ſulphuret.

* *W. Higgins, M. R. I. A.*

Take of ſulphur, or brimſtone in fine powder, four pounds; lime, well ſlaked and ſifted, twenty pounds; water, ſixteen gallons:—theſe are all to be well mixed and boiled for about half an hour in an iron veſſel, ſtirring them briſkly from time to time. Soon after the agitation of boiling is over, the ſolution of the ſulphuret of lime clears, and may be drawn off free from the inſoluble matter, which is conſiderable, and which reſts upon the bottom of the boiler (a). The liquor in this ſtate is pretty nearly of the colour of ſmall beer, but not quite ſo tranſparent.

Sixteen gallons of freſh water are afterwards to be poured upon the inſoluble dregs in the boiler, in order to ſeparate the whole of the ſulphuret from them. When this clears (being previouſly well agitated), it is alſo to be drawn off and mixed with the firſt liquor; to theſe again thirty-three gallons more of water may be added, which will reduce the liquor to a proper ſtandard for ſteeping the cloth.

Here we have (an allowance being made for evaporation, and for the quantity retained in the dregs) ſixty gallons of liquor from four pounds of brimſtone.

Although ſulphur by itſelf is not in any ſenſible degree ſoluble in water, and lime but very ſparingly ſo, water diſſolving but about one ſeven-hundredth part of its weight of lime; yet the ſulphuret of lime is highly ſoluble.

When the above proportion of lime and ſulphur is boiled with only twelve gallons of water, the ſulphuret partly cryſtallizes upon cooling; and when once cryſtallized it is not eaſy of ſolution.

SUMANYSTOWN, a village of Pennſylvania, in Montgomery county, ſituated on the E. ſide of Great Swamp creek, which empties into the Schuylkill above Norriton. It is 33 miles N. W. by N. of Philadelphia.—*Morſe.*

(a) Although lime is one of the conſtituent principles of the ſulphuret, yet being ſo intimately united to the ſulphur, it has no longer the property of lime; upon the ſame principle that ſulphuric acid in ſulphat of potaſh has not the property of that acid.

SUMNER, a county of Tenneffee, in Mero diftrict. According to the State cenfus of 1795, it contained 6,370 inhabitants, of whom 1,076 were flaves.—*ib.*

SUN (See ASTRONOMY-*Index*, Encycl.) is certainly that celeftial body which, of all others, fhould moft attract our attention. It has accordingly employed much of the time and meditation, not only of the aftronomer, but alfo of the fpeculative philofopher, in all ages of the world; and many hypothefes have been formed, and fome difcoveries made, refpecting the nature and the ufes of this vaft luminary.

Sir Ifaac Newton has fhewn, that the fun, by its attractive power, retains the planets of our fyftem in their orbits; he has alfo pointed out the method whereby the quantity of matter which it contains may be accurately determined. Dr Bradly has affigned the velocity of the folar light with a degree of precifion exceeding our utmoft expectation. Galliléo, Scheiner, Hevelius, Caffini, and others, have afcertained the rotation of the fun upon its axis, and determined the pofition of its equator. By means of the tranfit of Venus over the difk of the fun, our mathematicians have calculated its diftance from the earth, its real diameter and magnitude, the denfity of the matter of which it is compofed, and the fall of heavy bodies on its furface. We have therefore a very clear notion of the vaft importance and powerful influence of the fun on its planetary fyftem; but with regard to its internal conftruction, we are yet extremely ignorant. Many ingenious conjectures have indeed been formed on the fubject; a few of which we fhall mention as an introduction to Dr Herfchel's, of which, as it is the lateft, and perhaps the moft plaufible, we fhall give a pretty full account nearly in his own words.

The dark fpots in the fun, for inftance, have been fuppofed to be folid bodies revolving very near its furface. They have been conjectured to be the fmoke of volcanoes, or the fcum floating upon an ocean of fluid matter. They have alfo been taken for clouds. They were explained to be opaque maffes fwimming on the fluid matter of the fun, dipping down occafionally. It has been fuppofed that a fiery liquid furrounded the fun, and that by its ebbing and flowing the higheft parts of it were occafionally uncovered, and appeared under the fhape of dark fpots; and that by the return of the fiery liquid, they were again covered, and in that manner fucceffively affumed different phafes. The fun itfelf has been called a globe of fire, though perhaps metaphorically. The wafte it would undergo by a gradual confumption, on the fuppofition of its being ignited, has been ingenioufly calculated; and in the fame point of view its immenfe power of heating the bodies of fuch comets as draw very near to it has been affigned.

In the year 1779 there was a fpot on the fun which was large enough to be feen with the naked eye. By a view of it with a feven feet reflector, charged with a very high power, it appeared to be divided into two parts. The largeft of the two on the 19th of April, meafured 1' 8".06 in diameter, which is equal in length to more than 31,000 miles. Both together muft certainly have extended above 50,000. The idea of its being occafioned by a volcanic explofion violently driving away a fiery fluid, ought to be rejected (fays Dr Herfchel) on many accounts. "To mention only one, the great extent of the fpot is very unfavourable to fuch a fuppofition. Indeed a much lefs violent and lefs pernicious caufe may account for all the appearances of the fpot. When we fee a dark belt near the equator of the planet Jupiter, we do not recur to earthquakes and volcanoes for its origin. An atmofphere, with its natural changes, will explain fuch belts. Our fpot on the fun may be accounted for on the fame principles. The earth is furrounded by an atmofphere compofed of various elaftic fluids. The fun alfo has its atmofphere; and if fome of the fluids which enter into its compofition fhould be of a fhining brilliancy, in the manner that will be explained hereafter, while others are merely tranfparent, any temporary caufe which may remove the lucid fluid will permit us to fee the body of the fun through the tranfparent ones. If an obferver were placed on the moon, he would fee the folid body of the earth only in thofe places where the tranfparent fluids of our atmofphere would permit him. In others, the opaque vapours would reflect the light of the fun without permitting his view to penetrate to the furface of our globe. He would probably alfo find, that our planet had occafionally fome fhining fluids in its atmofphere; as, not unlikely, fome of our northern lights might not efcape his notice, if they happened in the unenlightened part of the earth, and were feen by him in his long dark night. Nay, we have pretty good reafon to believe, that probably all the planets emit light in fome degree; for the illumination which remains on the moon in a total eclipfe cannot be entirely afcribed to the light which may reach it by the refraction of the earth's atmofphere. For inftance, in the eclipfe of the moon October 22. 1790, the rays of the fun refracted by the atmofphere of the earth towards the moon, admitting the mean horizontal refraction to be 30' 50".8, would meet in a focus 189,000 miles beyond the moon; fo that confequently there could be no illumination from rays refracted by our atmofphere. It is, however, not improbable, that about the polar regions of the earth there may be refraction enough to bring fome of the folar rays to a fhorter focus. The diftance of the moon at the time of the eclipfe would require a refraction of 54' 6", equal to its horizontal parallax at that time, to bring them to a focus fo as to throw light on the moon.

The unenlightened part of the planet Venus has alfo been feen by different perfons; and not having a fatellite, thofe regions that are turned from the fun cannot poffibly fhine by a borrowed light; fo that this faint illumination muft denote fome phofphoric quality of the atmofphere of Venus.

In the inftance of the large fpot on the fun already mentioned, Dr Herfchel concludes, from appearances, that he viewed the real body of the fun itfelf, of which we rarely fee more than its fhining atmofphere. In the year 1783 he obferved a fine large fpot, and followed it up to the edge of the fun's limb. Here he took notice that the fpot was plainly depreffed below the furface of the fun, and that it had very broad fhelving fides. He alfo fufpected fome part, at leaft, of the fhelving fides to be elevated above the furface of the fun; and obferved that, contrary to what ufually happens, the margin of that fide of the fpot which was fartheft from the limb was the broadeft.

The luminous fhelving fide of a fpot may be explained ed by a gentle and gradual removal of the ſhining fluid, which permits us to ſee the globe of the ſun. As to the uncommon appearance of the broadeſt margin being on that ſide of the ſpot which was fartheſt from the limb when the ſpot came near the edge of it, we may ſurmiſe that the ſun has inequalities on its ſurface, which may poſſibly be the cauſe of it. For when mountainous countries are expoſed, if it ſhould chance that the higheſt parts of the landſcape are ſituated ſo as to be near that ſide of the margin or penumbra of the ſpot which is towards the limb, they may partly intercept our view of it when the ſpot is ſeen very obliquely. This would require elevations at leaſt five or ſix hundred miles high; but conſidering the great attraction exerted by the ſun upon bodies at its ſurface, and the ſlow revolution it has upon its axis, we may readily admit inequalities to that amount. From the centrifugal force at the ſun's equator, and the weight of bodies at its ſurface, he computes, that the power of throwing down a mountain by the exertion of the former, balanced by the ſuperior force of keeping it in its place of the latter, is near $6\frac{1}{2}$ times leſs on the ſun than on our equatorial regions; and as an elevation ſimilar to one of three miles on the earth would not be leſs than 334 miles on the ſun, there can be no doubt but that a mountain much higher would ſtand very firmly. The little denſity of the ſolar body ſeems alſo to be in favour of the height of its mountains; for, *cæteris paribus*, denſe bodies will ſooner come to their level than rare ones. The difference in the vaniſhing of the ſhelving ſide, inſtead of explaining it by mountains, may alſo, and perhaps more ſatisfactorily be accounted for from the real difference of the extent, the arrangement, the height, and the intenſity of the ſhining fluid, added to the occaſional changes that may happen in theſe particulars during the time in which the ſpot approaches to the edge of the diſk. However, by admitting large mountains on the face of the ſun, we ſhall account for the different opinions of two eminent aſtronomers; one of whom believed the ſpots depreſſed below the ſurface of the ſun, while the other believed them elevated above it. For it is not impoſſible that ſome of the ſolar mountains may be high enough occaſionally to project above the ſhining elaſtic fluid, when, by ſome agitation or other cauſe, it is not of the uſual height; and this opinion is much ſtrengthened by the return of ſome remarkable ſpots which ſerved Caſſini to aſcertain the period of the ſun's rotation. A very high country, or chain of mountains, may oftener become viſible, by the removal of the obſtructing fluid, than the lower regions, on account of its not being ſo deeply covered with it.

In 1791 the Doctor examined a large ſpot on the ſun, and found it evidently depreſſed below the level of the ſurface. In 1792 he examined the ſun with ſeveral powers from 90 to 500, when it appeared evidently, that the black ſpots are the opaque ground, or body of the ſun; and that the luminous part is an atmoſphere, which, being interrupted or broken, gives us a tranſient glimpſe of the ſun itſelf. He perceived likewiſe, that the ſhining ſurface of the ſun is unequal, many parts of it being elevated and others depreſſed; and that the elevations, to which Hevelius gave the name of *faculæ*, ſo far from reſembling torches, were rather like the ſhrivelled elevations upon a dried apple, extended in length, and moſt of them joined together, making waves or waving lines. The faculæ being elevations, very ſatisfactorily explains the reaſon why they diſappear towards the middle of the ſun, and reappear on the other margin; for about the place where we loſe them, they begin to be edgewiſe to our view; and if between the faculæ ſhould lie dark ſpots, they will moſt frequently break out in the middle of the ſun, becauſe they are no longer covered by the ſide-views of theſe faculæ.

The Doctor gives a very particular account of all his obſervations, which ſeem to have been accurately made, and we need not ſcarcely add with excellent teleſcopes. For that account, however, we muſt refer to the memoir itſelf, and haſten to lay before our readers the reſult of his obſervations. "That the ſun (ſays he) has a very extenſive atmoſphere, cannot be doubted; and that this atmoſphere, conſiſts of various elaſtic fluids, that are more or leſs lucid and tranſparent, and of which the lucid one is that which furniſhes us with light, ſeems alſo to be fully eſtabliſhed by all the phenomena of its ſpots, of the faculæ, and of the lucid ſurface itſelf. There is no kind of variety in theſe appearances but what may be accounted for with the greateſt facility, from the continual agitation which, we may eaſily conceive, muſt take place in the regions of ſuch extenſive elaſtic fluids.

"It will be neceſſary, however, to be a little more particular as to the manner in which I ſuppoſe the lucid fluid of the ſun to be generated in its atmoſphere. An analogy that may be drawn from the generation of clouds in our own atmoſphere, ſeems to be a very proper one, and full of inſtruction. Our clouds are probably decompoſitions of ſome of the elaſtic fluids of the atmoſphere itſelf, when ſuch natural cauſes, as in this grand chemical laboratory are generally at work, act upon them; we may therefore admit, that in the very extenſive atmoſphere of the ſun, from cauſes of the ſame nature, ſimilar phenomena will take place; but with this difference, that the continual and very extenſive decompoſitions of the elaſtic fluids of the ſun are of a phoſphoric nature, and attended with lucid appearances, by giving out light.

"If it ſhould be objected, that ſuch violent and unremitting decompoſitions would exhauſt the ſun, we may recur again to our analogy, which will furniſh us with the following reflections. The extent of our own atmoſphere, we ſee, is ſtill preſerved, notwithſtanding the copious decompoſitions of its fluids in clouds and falling rain; in flaſhes of lightning, in meteors, and other luminous phenomena; becauſe there are freſh ſupplies of elaſtic vapours continually aſcending to make good the waſte occaſioned by thoſe decompoſitions. But it may be urged, that the caſe with the decompoſition of the elaſtic fluids in the ſolar atmoſphere would be very different, ſince light is emitted, and does not return to the ſun, as clouds do to the earth when they deſcend in ſhowers of rain. To which I anſwer, that, in the decompoſition of phoſphoric fluids, every other ingredient but light may alſo return to the body of the ſun. And that the emiſſion of light muſt waſte the ſun, is not a difficulty that can be oppoſed to our hypotheſis: for as it is an evident fact that the ſun does emit light, the ſame objection, if it could be one, would equally militate againſt every other aſſignable way to account for the phenomenon.

"There are, moreover, conſiderations that may leſſen the preſſure of this alleged difficulty. We know the exceeding ſubtilty of light to be ſuch, that in ages of time its emanation from the ſun cannot very ſenſibly leſſen the ſize of this great body. To this may be added, that very poſſibly there may always be ways of reſtoration to compenſate for what is loſt by the emiſſion of light, though the manner in which this can be brought about ſhould not appear to us. Many of the operations of Nature are carried on in her great laboratory which we cannot comprehend, but now and then we ſee ſome of the tools with which ſhe is at work. We need not wonder that their conſtruction ſhould be ſo ſingular as to induce us to confeſs our ignorance of the method of employing them; but we may reſt aſſured that they are not a mere *luſus naturæ*." Here he alludes to the great number of ſmall teleſcopic comets; which he ſuppoſes, as others had done before him, may be employed to reſtore to the ſun what had been loſt by the emiſſion of light. "My hypotheſis, however, (continues he) does not lay me under any obligation to explain how the ſun can ſuſtain the waſte of light, nor to ſhew that it will ſuſtain it for ever; and I ſhould alſo remark that, as in the analogy of generating clouds, I merely allude to their production as owing to a decompoſition of ſome of the elaſtic fluids of our atmoſphere, that analogy, which firmly reſts upon the fact, will not be leſs to my purpoſe, to whatever cauſe theſe clouds may owe their origin. It is the ſame with the lucid clouds, if I may ſo call them, of the ſun. They plainly exiſt, becauſe we ſee them; the manner of their being generated may remain an hypotheſis—and mine, till a better can be propoſed, may ſtand good; but whether it does or not, the conſequences I am going to draw from what has been ſaid will not be affected by it."

Before he proceeds to draw theſe conſequences, he informs us that, according to the above theory, a dark ſpot in the ſun is a place in its atmoſphere, which happens to be free from luminous decompoſitions; that faculæ are, on the contrary, more copious mixtures of ſuch fluids as decompoſe each other; and that the regions, in which the luminous ſolar clouds are formed, adding thereto the elevation of the faculæ, cannot be leſs than 1843, nor much more than 2765 miles in depth. It is true, continues he, that in our atmoſphere the extent of the clouds is limited to a very narrow compaſs; but we ought rather to compare the ſolar ones to the luminous decompoſitions which take place in our *aurora borealis*, or luminous arches, which extend much farther than the cloudy regions. The denſity of the luminous ſolar clouds though very great, may not be exceedingly more ſo than that of our *aurora borealis*. For if we conſider what would be the brilliancy of a ſpace two or three thouſand miles deep, filled with ſuch corruſcations as we ſee now and then in our atmoſphere, their apparent intenſity, when viewed at the diſtance of the ſun, might not be much inferior to that of the lucid ſolar fluid.

From the luminous atmoſphere of the ſun, he proceeds to its opaque body; which, by calculation from the power it exerts upon the planets, we know to be of great ſolidity; and from the phenomena of the dark ſpots, many of which, probably on account of their high ſituations, have been repeatedly ſeen, and otherwiſe denote inequalities in their level, we ſurmiſe that its ſurface is diverſified with mountains and valleys.

What has been ſaid, enables us to come to ſome very important concluſions, by remarking, that this way of conſidering the ſun and its atmoſphere removes the great diſſimilarity we have hitherto been uſed to find between its condition and that of the reſt of the great bodies of the ſolar ſyſtem.

The ſun, viewed in this light, appears to be nothing elſe than a very eminent, large, and lucid planet, evidently the firſt, or, in ſtrictneſs of ſpeaking, the only primary one of our ſyſtem, all others being truly ſecondary to it. Its ſimilarity to the other globes of the ſolar ſyſtem with regard to its ſolidity, its atmoſphere, and its diverſified ſurface, the rotation upon its axis, and the fall of heavy bodies, leads us on to ſuppoſe that it is moſt probably alſo inhabited, like the reſt of the planets, by beings whoſe organs are adapted to the peculiar circumſtances of that vaſt globe.

It may, however, not be amiſs to remove a certain difficulty, which ariſes from the effect of the ſun's rays upon our globe. The heat which is here, at the diſtance of 95 millions of miles, produced by theſe rays, is ſo conſiderable, that it may be objected, that the ſurface of the globe of the ſun itſelf muſt be ſcorched up beyond all conception.

This may be very ſubſtantially anſwered by many proofs drawn from natural philoſophy, which ſhew that heat is produced by the ſun's rays only when they act upon a calorific medium; they are the cauſe of the production of heat, by uniting with the matter of fire which is contained in the ſubſtances that are heated; as the colliſion of flint and ſteel will inflame a magazine of gunpowder, by putting all the latent fire it contains into action. But an inſtance or two of the manner in which the ſolar rays produce their effect, will bring this home to our moſt common experience.

On the tops of mountains of a ſufficient height, at an altitude where clouds can very ſeldom reach to ſhelter them from the direct rays of the ſun, we always find regions of ice and ſnow. Now if the ſolar rays themſelves conveyed all the heat we find on this globe, it ought to be hotteſt where their courſe is leaſt interrupted. Again, our aëronauts all confirm the coldneſs of the upper regions of the atmoſphere; and ſince, therefore, even on our earth, the heat of any ſituation depends upon the aptneſs of the medium to yield to the impreſſion of the ſolar rays, we have only to admit, that on the ſun itſelf, the elaſtic fluids compoſing its atmoſphere, and the matter on its ſurface, are of ſuch a nature as not to be capable of any exceſſive affection from its own rays: and indeed this ſeems to be proved by the copious emiſſion of them; for if the elaſtic fluids of the atmoſphere, or the matter contained on the ſurface of the ſun, were of ſuch a nature as to admit of an eaſy chemical combination with its rays, their emiſſion would be much impeded.

Our author then proceeds to ſupport his theory by analogical reaſoning; but as theſe will occur to ſuch of our readers as are converſant with the ſpeculations of aſtronomers, we paſs on to his reflections upon the conſequences of this theory. "That the ſtars are ſuns can hardly admit of a doubt. Their immenſe diſtance would perfectly exclude them from our view, if the light they ſend

send us were not of the solar kind. Besides, the analogy may be traced much farther. The sun turns on its axis; so does the star Algol; so do the stars called β Lyræ, δ Cephei, η Antinoi, ο Ceti, and many more; most probably all. From what other cause can we so probably account for their periodical changes? Again, our sun has spots on its surface; so has the star Algol, and so have the stars already named, and probably every star in the heavens. On our sun these spots are changeable; so they are on the star ο Ceti, as evidently appears from the irregularity of its changeable lustre, which is often broken in upon by accidental changes while the general period continues unaltered. The same little deviations have been observed in other periodical stars, and ought to be ascribed to the same cause. But if stars are suns, and suns are inhabitable, we see at once what an extensive field for animation opens itself to our view.

"It is true, that analogy may induce us to conclude, that since stars appear to be suns, and suns, according to the common opinion, are bodies that serve to enlighten, warm, and sustain a system of planets, we may have an idea of numberless globes that serve for the habitation of living creatures. But if these suns themselves are primary planets, we may see some thousands of them with our own eyes, and millions by the help of telescopes, when at the same time the same analogical reasoning still remains in full force with regard to the planets which these suns may support."

The Doctor then observes, that from other considerations, the idea of suns or stars being *merely* the supporters of systems of planets, is not absolutely to be admitted as a general one. "Among the great number of very compressed clusters of stars I have given (says he) in my catalogues, there are some which open a different view of the heavens to us. The stars in them are so very close together, that, notwithstanding the great distance at which we may suppose the cluster itself to be, it will hardly be possible to assign any sufficient mutual distance to the stars composing the cluster, to leave room for crowding in those planets, for whose support these stars have been, or might be, supposed to exist. It should seem, therefore, highly probable, that they exist for themselves; and are, in fact, only very capital, *lucid*, primary planets, connected together in one great system of mutual support.

"The same remark may be made with regard to the number of very close double stars, whose apparent diameters being alike, and not very small, do not indicate any very great mutual distance: from which, however, must be deducted all those where the different distances may be compensated by the real difference in their respective magnitudes.

"To what has been said may be added, that, in some parts of the milky way, where yet the stars are not very small, they are so crowded, that in the year 1792, Aug. 22. I found by the gauges that, in 41 minutes of time, no less than 258,000 of them had passed through the field of view of my telescope.

"It seems, therefore, upon the whole, not improbable, that in many cases stars are united in such close systems as not to leave much room for the orbits of planets or comets; and that consequently, upon this account also, many stars, unless we would make them mere useless brilliant points, may themselves be lucid planets, perhaps unattended by satellites."

What a magnificent idea does this theory give of the universe, and of the goodness, as well as power, of its Author? And how cold must be that heart, and clouded that understanding, who, after the contemplation of it, can for one moment listen to the atheistical doctrines of those men who presume to account for all the phenomena of nature by chemical affinities and mechanical attraction? The man who, even in his heart, can say, that such an immense system, differing so widely in the structure of the different parts of it, but everywhere crowded with life, is the effect of unintelligent agency, is indeed, to use the emphatic language of an ancient astronomer—*a fool*.

Sun ‖ Sunda.

SUNAPEE, a lake and mountain in Cheshire county, New-Hampshire. The lake is about 8 or 9 miles long, and 3 broad, and sends its waters through Sugar river west, 14 miles to Connecticut river. The mountain stands at the south end of the lake.—*Morse*.

SUNBURY, a county of the British province of New-Brunswick. It is situated on the river St John, at the head of the Bay of Fundy; and contains 8 townships, viz. Conway, Gage-Town, Burton, Sunbury, St Annes, Wilmot, Newton, and Maugerville. The three last of these were settled from Massachusetts, Connecticut, &c. The lands are generally pretty level, and tolerably fertile, abounding with variety of timber.—*ib*.

Sunbury, the chief town of Northumberland county, Pennsylvania; situated near where Fort Augusta was erected, on the E. side of Susquehannah river, just below the junction of the E. and W. branches of that river, in lat. about 40 52 N. It is regularly laid out, and contains a court-house, brick gaol, a Presbyterian and German Lutheran church, and about 100 dwelling-houses. Here the river is about half a mile broad, and at the ferry opposite Northumberland, about a mile higher, is $\frac{4}{5}$ths of a mile. It is about 76 miles above Reading, and 120 N. W. of Philadelphia.—*ib*.

Sunbury, a port of entry and post-town of Georgia, beautifully situated in Liberty county, at the head of St Catherine's Sound, on the main, between Medway and Newport rivers, about 15 miles S. of Great Ogeeche river. The town and harbour are defended from the fury of the sea by the N. and S. points of St Helena and St Catherine's Islands; between is the bar and entrance into the sound: the harbour is capacious and safe, and has water enough for ships of great burden. It is a very pleasant healthy town, and is the resort of the planters from the adjacent country, during the sickly months. It was burnt during the late war, but has since been rebuilt. An academy was established here in 1788, which has been under an able instructor, and proved a very useful institution. It is 40 miles S. of Savannah, and 974 from Philadelphia. —*ib*.

SUNCOOK, a small plantation in York county, District of Maine, which with Bromfield contains 250 inhabitants.—*ib*.

SUNDA, Straits of, are formed by the approach of the south-east extremity of the island of Sumatra to the north-west extremity of the island of Java (See these islands, *Encycl.*). The straits are interspersed with a number of small isles; the whole displaying a scenery scarcely to be exceeded in the softness, richness, and gaiety of its appearance. The two great islands, which are low, and in some places marshy near the shore, rise afterwards, in a gradual slope, towards the interior of the country, admitting in their ascent every variety of situation, and all the different tints of verdure. Of the smaller islands, a few have steep and naked sides, such as one in the middle of the strait, which the English navigators have distinguished, on that account, by the name of Thwart-the way, and two very small round ones, called, from their figures, the CAP and BUTTON (see these islands, *Suppl.*); but most of the others are entirely level, founded upon beds of coral, and covered with trees. Some of these islands are surrounded with a white sandy beach, visited frequently by turtle; but most of them are adorned with thick shrubbery to the water's edge, the roots being washed by the sea, or the branches dipping into it; and on the outside are shoals, in which a multitude of little aquatic animals are busied in framing calcarious habitations for their residence and protection. Those fabrics gradually emerge above the surface of the water, and at length, by the adventitious adhesion of vegetable matter, giving birth to plants and trees, become new islands, or add to the size of those already produced by the same means. It is impossible not to be struck with the diversified operations of Nature for obtaining the same end, whether employed in originally fixing the granite foundation of the Brazils, or in throwing up, by some sudden and subsequent convulsion, the island of Amsterdam, or in continuing to this hour, through the means of animated beings, the formation of new lands in the Straits of Sunda.—*Sir George Staunton's Account of the British Embassy to China.*

SUNDERLAND, a township of Vermont, Bennington county, 16 miles N. E. of Bennington, and contains 414 inhabitants. A lead mine has been lately discovered in this township.—*Morse.*

SUNDERLAND, a township of Massachusetts, situated in Hampshire county, on the E. side of Connecticut river, about 10 miles N. of Hadley and 100 W. of Boston. There is here a handsome Congregational church, and 73 houses, lying chiefly on one street. It was incorporated in 1718, and contains 462 inhabitants.—*ib.*

SUNNUD, a grant, patent, or charter, in Bengal.

SUPAY URCO, or *Devil's Hill*, a remarkable eminence in the province of Quito, in Peru, between the vallies of Chugui-pata, and those of Paute. It has its name from a fabulous story of enchantment, propagated by a superstitious Spaniard. It is thought to contain rich mines.—*Morse.*

SUPERIOR, *Lake*, formerly termed the Upper Lake, from its northern situation. It may justly be termed the Caspian Sea of America, and is supposed to be the largest body of fresh water on the globe. According to the French charts it is 1,500 miles in circumference. A great part of the coast is bounded by rocks and uneven ground. It is situated between 46 and 50 N. lat. and between 84 30 and 92 W. long. The water is very clear, and transparent. If the sun shines bright, it is impossible through this medium to look at the rocks at the bottom, above a minute or two. Although the water, at the surface, is much warmed by the heat of the sun, yet, when drawn up at about a fathom depth, it is very cold. Storms are more dreadful here than on the ocean. There are many islands in this lake; two of them have each land enough, if proper for cultivation, to form a considerable province; especially Isle Royal, which is not less than 100 miles long, and in many places 40 broad. The natives suppose these islands to be the residence of the Great Spirit. Many rivers empty their waters into this mighty reservoir; of these, one is called *Nipegon*, another *Michipicooton*. This lake discharges its waters from the S. E. corner through the Straits of St Marie, which are about 40 miles long, into Lake Huron. Lake Superior, although about 40 rivers empty into it, many of which are large, yet it does not appear that one-tenth part of the waters which it receives, is discharged by the above mentioned strait: great part of the waters evaporate; and Providence doubtless makes use of this inland sea to furnish the interior parts of the country with that supply of vapours, without which, like the interior parts of Africa, they must have been a mere desert. A number of tribes live around Lake Superior, but little is known respecting them. The following extract from the journal of a late traveller will be acceptable to the curious.

"Mr M—— about the year 1790, departed from Montreal with a company of about 100 men, under his direction, for the purpose of making a tour through the Indian country, to collect furs, and to make such remarks on its soil, waters, lakes, mountains, manners and customs of its inhabitants as might come within his knowledge and observation. He pursued his route from Montreal, entered the Indian country, and coasted about 300 leagues along the banks of Lake Superior, from thence to the *Lake of the Woods*, of which he took an actual survey, and found it to be 36 leagues in length; from thence to the lake *Ounipique*, of which he has also a description. The tribes of the Indians which he passed through, were called the *Maskego* tribe, *Shepeweyau*, *Cithinistinee*, *Great Belly Indians*, *Beaver Indians*, *Blood Indians*, the *Black-feet Tribe*, the *Snake Indians*, *Ossnobians*, *Shiveytoon Tribe*, *Mandon Tribe*, *Paunees*, and several others, who in general were very pacific and friendly towards him, and are great admirers of the best hunting horses, in which the country abounds. The horses prepared by them for hunters, have large holes cut above their natural nostrils, for which they give as a reason, that those prepared in this manner will keep their breath longer than the others, which are not thus prepared: From experience, knowledge is gained, and the long practice of this custom, consequently on these trials, must have convinced them of the truth and utility of the experiment; otherwise we can hardly suppose they would torture their best horses in this manner, if some advantage was not derived from the measure. In pursuing his route, he found no difficulty in obtaining a guide to accompany him from one nation to the other, until he came to the *Shining Mountains* or *Mountains of Bright Stones*, where, in attempting to pass, he was frustrated by the hostile appearance of the Indians who inhabit that part of the country. The consequence of which was, he was disappointed in his intention and obliged to turn his back upon them. Having collected a number of Indians he he went forward again, with an intention to force his way over thoſe mountains, if neceſſary and practicable, and to make his way to Cook's river, on the N. W. coaſt of America, ſuppoſed by him to be about 300 leagues from the mountains; but the inhabitants of the mountains again met him with their bows and arrows, and ſo ſuperior were they in numbers to his little force, that he was obliged to flee before them. Finding himſelf thus totally diſappointed in the information he was in hopes to obtain, he was obliged to turn his back upon that part of the country for which his thirſting heart had long panted. Cold weather coming on, he built huts for himſelf and party in the *Oſſnobian* country, and near the ſource of a large river, called the *Oſſnobian river*, where they tarried during the continuance of the cold ſeaſon, and until ſome time in the warmer months. Previous to his departure from Montreal, he had ſupplied himſelf with ſeveral kinds of ſeeds, and before his huts he laid out a ſmall garden, which the natives obſerving, called them ſlaves, for digging up the ground, nothing of that kind being done by them, they living wholly on animal food; bread is unknown to them; to ſome he gave ſome remnants of hard bread, which they chewed and ſpit out again, calling it rotten wood. When his onions, &c. were ſomewhat advanced in their growth, he was often ſurprized to find them pulled up; determining therefore to know from what cauſe it proceeded, he directed his men to keep watch, who found that the Indian children, induced by motives of curioſity, came with ſticks, thruſt them through the poles of his fence, to aſcertain and ſatisfy themſelves, what the things of the white men were, and in what manner they grew, &c. The natives of this country have no fixed or permanent place of abode, but live wholly in tents made of buffaloe and other hides, and with which they travel from one place to another like the Arabs; and ſo ſoon as the feed for their horſes is expended, they remove their tents to another fertile ſpot, and ſo on continually, ſcarcely ever returning to the ſame ſpots again."—*ib.*

SUPERPARTICULAR Proportion, or Ratio, is that in which the greater term exceeds the leſs by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT Proportion, or Ratio, is when the greater term contains the leſs term once, and leaves ſome number greater than 1 remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $1\frac{2}{3}$;

of 7 to 10, which is equal to that of 1 to $1\frac{3}{7}$; &c.

SUPPLEMENT, of an Arch or Angle, in geometry or trigonometry, is what it wants of a ſemicircle, or of 180°; as the *compliment* is what it wants of a quadrant, or of 90°. So, the ſupplement of 50° is 130°; as the compliment of it is 40°.

SURINAM, a province or diſtrict in South-America, belonging to the Dutch.—*Morſe.*

Surinam, a beautiful river of South-America, and in Dutch Guiana; three-quarters of a mile wide at its mouth; navigable for the largeſt veſſels 12 miles, and for ſmaller veſſels 60 or 70 miles further. Its banks, quite to the water's edge, are covered with evergreen mangrove trees, which render the proſpect very delightful. The entrance is guarded by a fort and two redoubts, but not of any great ſtrength. At 6 miles up, the Commanwine falls into it, and on the point of land between the two rivers are the forts. The town of Surinam is in lat. 6 10 N. and long. 55 22 W. The beſt anchorage is under Zelandia Fort.—*ib.*

SURRY, a county of N. Carolina, in Saliſbury diſtrict; bounded eaſt by Stokes, and weſt by Wilkes. It contains 7,191 inhabitants, including 698 ſlaves. The Moravian ſettlements of Wachovia are in this county. Near the river Yadkin is a forge, which manufactures bar-iron. The Ararat or Pilot Mountain, about 16 miles north-weſt of Salem, draws the attention of every curious traveller in this part of the State. It is diſcernible at the diſtance of 60 or 70 miles, overlooking the country below. It was anciently called the Pilot, by the Indians, as it ſerved them for a beacon, to conduct their routes in the northern and ſouthern wars. On approaching it, a grand diſplay of nature's workmanſhip in rude dreſs, is exhibited. From its broad baſe, the mountain riſes in eaſy aſcent, like a pyramid, near a mile high, to where it is not more than the area of an acre broad; when, on a ſudden, a vaſt ſtupendous rock, having the appearance of a large caſtle, with its battlements, erects its perpendicular height to upwards of 300 feet, and terminates in a flat, which is generally as level as a floor. To aſcend this precipice, there is only one way, which, through cavities and fiſſures of the rock, is with ſome difficulty and danger effected. When on the ſummit, the eye is entertained with a vaſt, delightful proſpect of the Apalachian mountains, on the north, and a wide, extended level country below, on the ſouth; while the ſtreams of the Yadkin and Dan, on the right and left hand, are diſcovered at ſeveral diſtant places, winding their way, through the fertile low grounds, towards the ocean.—*ib.*

Surry, a county of Virginia, bounded north by James river which ſeparates it from Charles City county, eaſt by Iſle of Wight, and weſt by Prince George's county. It contains 6,227 inhabitants, of whom 3,097 are ſlaves.—*ib.*

Surry, a townſhip of New-Hampſhire, in Cheſhire county, containing 448 inhabitants. It lies eaſt of Walpole, adjoining, and was incorporated in 1769.—*ib.*

SUSQUEHANNAH *River*, riſes in Lake Uſtayantho, in the State of New-York, and runs in ſuch a ſerpentine courſe that it croſſes the boundary line between the States of Pennſylvania and New-York, three times. It receives the Tyoga river in N. lat. 41 57. Afterwards it proceeds ſouth-eaſt to Wyoming, without any obſtruction by falls, and then ſouth-weſt over Wyoming falls, till, at Sunbury, in lat. 41 it meets the weſt branch of Suſquehannah, which is navigable 90 miles from its mouth. From Sunbury the river is paſſable with boats to Harriſburg and Middleton on the Swatara. About 15 miles above Harriſburg, it receives the Juniatta, from the north-weſt, proceeding from the Alleghany mountains and flowing through a broken country. Hence it takes its courſe about ſouth-eaſt, until it falls into the head of Cheſapeak Bay, juſt below Havre de Grace. It is about a mile wide at its mouth, and navigable only 20 miles, the navigation being obſtructed beyond that by the Rapids. The inland navigation between Schuylkill and Suſquehannah, will bring by water to Philadelphia, the trade of a moſt fertile country of about 1000 miles ſquare, or 6,000,000 acres

acres

acres of land. If this can be accomplifhed, an inland navigation may be eafily made to the Ohio and to Lake Erie, which would at once open a communication with above 2,000 miles extent of weftern country, viz. with all the great lakes, together with the countries which lie on the waters of Miffiffippi, Miffouri, and all their branches. The water communication between Schuylkill and Sufquehannah, which is the foul of all this, will be about 60 miles, as the navigation muft go, although the diftance on a line is only 40 miles. This tract is cut by two creeks, the Quitapahilla and the Tulpehoken. Thefe two creeks lead within 4 miles of each other; the level of their head waters is nearly the fame, and the fpace between them makes the height of land, or, as it is commonly called, the *crown land* between the two rivers which is nearly on a plain, and the bottom of the canal, through which the navigation muft pafs, will no where rife more than 30 feet above the level of the head waters of the two creeks above-mentioned, nor fo much as 200 feet above the level of the waters of Sufquehannah or Schuylkill. The Company, inftituted the 29th of Sept. 1791, has a capital of 1000 fhares at 400 dollars each, payable at fuch time as the Company fhall direct. The work is already commenced. Coal of an excellent quality is found on feveral parts of this river, particularly at Wyoming.—*ib.*

SUSSEX, the north-wefternmoft county of New-Jerfey. It is mountainous and healthy, and has feveral iron mines; and works have been erected for the manufacture of bar and pig iron. It produces excellent crops of wheat; and in no part of the State are greater herds of cattle. The produce is floated down the Delaware in boats and rafts. Here are 5 Prefbyterian churches, 2 for Anabaptifts, 1 for German Lutherans, and 1 for Quakers. It contains 12 townfhips; the chief of which are Newton, Greenwich, Hardyfton, Knowltown, and Oxford. The population is 19,500 including 439 flaves. It is bounded N. E. by the State of New-York, N. W. by Delaware river, which feparates it from Northampton county, in Pennfylvania, and fouth-eaft and fouth by Morris and Hunterdon counties. Paulin's Kill is here navigable for fmall craft 15 miles. The Mufconetcony, which divides the county from Hunterdon, is capable of beneficial improvements, as is the Pequeft or Pequafet, between the above-mentioned rivers. The court-houfe in this county is 13 miles fouth-weft of Hamburg; 38 N. E. of Eafton, in Pennfylvania; 41 fouth-weft of Gofhen, in New-York; and 108 N. by E. of Philadelphia. The village at this place is called Newton.—*ib.*

Sussex, a county of Virginia; bounded N. E. by Surry, and fouth-weft by Dinwiddie. It contains 10,554 inhabitants, including 5,387 flaves.—*ib.*

Sussex, a maritime county of Delaware State, bounded weft and fouth by the State of Maryland, north-eaft by Delaware Bay, eaft by the Atlantic Ocean, and north by Kent county. It contains 20,488 inhabitants, including 4,025 flaves. Cape Henlopen is in the north eaftern part of the county. Chief town, Georgetown.—*ib.*

SUTTON (Thomas Efq;), founder of the charter-houfe, was born at Knaith in Lincolnfhire in 1532, of an ancient and genteel family. He was educated at Eton-fchool, and probably at Cambridge, and ftudied the law in Lincoln's Inn; but this profeffion not fuiting his difpofition, he travelled into foreign countries, and made fo long a ftay in Holland, France, Spain, and Italy, as to acquire the languages of thofe various nations. During his abfence, his father died, and left him a confiderable fortune. On his return home, being a very accomplifhed gentleman, he became fecretary to the earl of Warwick and his brother the earl of Leicefter. By the former of thefe noblemen, in 1569, he was appointed mafter of the ordnance at Berwick; and diftinguifhing himfelf greatly in that fituation, on the rebellion which at that time broke out in the north, he obtained a patent for the office of mafter-general of the ordnance for that diftrict for life. He is named as one of the chiefs of thofe 1500 men who marched into Scotland, by the order of Queen Elizabeth, to the affiftance of the regent, the earl of Morton, in 1573; and he commanded one of the five batteries which obliged the ftrong caftle of Edinburg to furrender to the Englifh. He purchafed of the bifhop of Durham the manors of Gatefhead and Wickham; which, producing coal mines, became to him a fource of extraordinary wealth. In 1580, he was reputed to be worth L. 50,000.

Soon after this, he married a rich widow, who brought him a confiderable eftate; and taking up the bufinefs of a merchant, riches flowed in to him with every tide. He is faid to have had no lefs than thirty agents abroad. He was likewife one of the chief victuallers of the navy; and feems to have been mafter of the barque called Sutton, in the lift of volunteers attending the Englifh fleet againft the Spanifh armada. It is probable, alfo, that he was a principal inftrument in the defeat of it, by draining the bank of Genoa of that money with which Philip intended to equip his fleet, and thereby hindering the invafion for a whole year. He is likewife faid to have been a commiffioner for prizes under Lord Charles Howard, High Admiral of England; and going to fea with letters of marque, he took a Spanifh fhip worth L. 20,000. His whole fortune, at his death, appears to have been in land L. 5,000 *per annum;* in money, upwards of L. 60,000; the greateft eftate in the poffeffion of any private gentleman till much later times. He lived with great munificence and hofpitality; but lofing his lady in 1602, he retired from the world, leffened his family, and lived in a private frugal manner; and, having no iffue, refolved to diftinguifh his name by fome important charity. Accordingly, he purchafed of the Earl of Suffolk, Howard-Houfe, or the late diffolved charter-houfe, near Smithfield, for the fum of L. 13,000, where he founded the prefent hofpital, in 1611, for the relief of poor men and children. Before he had fixed upon this defign, the court endeavoured to divert him from his purpofe, and to engage him to make Charles I. then Duke of York, his heir, by conferring on him a peerage; but being free from ambition, and now near his grave, the luftre of the coronet could not tempt him to change his plan. He died the 11th of December, 1611, at Hackney, aged 79. His body was conveyed, with the moft folemn proceffion, to Chrift-church in London, and there depofited, till 1614, when it was removed to the charter-houfe, and interred in a vault on the north fide of the chapel, under a magnificent tomb.

Sutton, a townfhip of New-Hampfhire, Hillfborough

rough county, containing 520 inhabitants. It was firſt called Perryſtown, and was incorporated in 1784. —*Morse.*

Sutton, a townſhip in Worceſter county, Maſſachuſetts, 46 miles W. S. W. of Boſton, and 10 miles S. by E. of Worceſter. It was incorporated in 1718, and contains 2,642 inhabitants. Here are 10 griſt-mills, 6 ſaw-mills, 3 fulling-mills, a paper mill, an oil-mill, and 7 trip-hammers. There are 5 ſcythe and ax-makers, one hoe-maker, ſeveral who work at nail-making, and 6 works for making pot-aſh. Here are found ginſeng and the cohuſh-root. The cavern, commonly called *Purgatory*, in the ſouth-eaſtern part of the town, is a natural curioſity. Bodies of ice are found here in June, although the deſcent is to the ſouth.—*ib.*

SUWOROW (a) Rimnikski (Count Alexander), was a man ſo eminent in his profeſſion, that, if war be an art founded on ſcience, it would be improper not to give ſome account of his life in a Work of this nature. Various accounts of him, indeed, are already in the hands of the public; but they differ ſo much from one another in the pictures which they preſent of the *man*, that it is not eaſy, if it be always poſſible, to diſtinguiſh truth from falſehood. With reſpect to the talents of the *General*, there is not room for the ſame difference of repreſentation; becauſe a train of military ſucceſſes, almoſt unrivalled, has rendered theſe conſpicuous to all Europe. In the ſhort detail that our limits permit us to give of the life of this ſingular man, we ſhall avail ourſelves of all the information, public and private, which we have been able to obtain, and believe to be authentic; and we hope to make our readers acquainted with ſome particulars reſpecting his perſon and domeſtic habits which are not yet generally known.

The family of Suworow is ſaid to have been from Sweden, and of a noble deſcent. The firſt of this name ſettled in Ruſſia about the latter end of the laſt century; and having engaged in the wars againſt the Tartars and the Poles, were rewarded by the Czars of that period with lands and peaſants. Baſil, the father of our hero, is ſaid to have been the godſon of Peter the Great; to have been held in high eſtimation for his political knowledge and extenſive erudition; and to have enjoyed, at his death, the two-fold rank of General and Senator*.

As this account is given by a man who profeſſes to have formed an intimate acquaintance with Suworow himſelf, it ought to be correct; and yet we cannot help entertaining ſome doubts of its truth, or at leaſt of its accuracy. It is well known that extenſive erudition was in no eſteem in Ruſſia at the period when Baſil Suworow is here ſaid to have been ſo learned; and it is likewiſe known, that if, by erudition, be meant a knowledge of ancient literature, it was even deſpiſed, at a much later period, by all who were at once noble, and poſſeſſed of lands and peaſants (See Russia, *Encycl.*) The truth is, as we have learned from unqueſtionable authority, that the family of Suworow was ancient and reſpectable; but being far from affluent, and their little property lying at the very extremity of the empire, we have reaſon to believe, that the ſubject of this memoir was the firſt of the family that ever was at court. Baſil, however, if his anceſtors were from Sweden, may have been free from the Ruſſian prejudices againſt Greek and Latin; and this is the more probable, that he certainly gave a learned education to his ſon.

That ſon, Alexander Baſilowitch Suworow, was, according to the author already quoted, born in the year 1730; we have ſome reaſon to believe, that he was not born before 1732. His father had deſtined him, we are told, for the robe; but his early inclinations impelled him to the profeſſion of a ſoldier; and in 1742 he was enrolled as a fuſilier in the guards of Seimonow. He was afterwards a corporal, then a ſerjeant, and, in 1754, he quitted the guards with the brevet of Lieutenant in the army. He made his firſt campaign in the ſeven years war againſt the Pruſſians, in the year 1759, entering upon actual ſervice under Prince Wolgonſki. As ſenior officer on duty, he attended on the commander in chief Count Fermor, who, admiring the conſummate reſolution which he appeared to poſſeſs, favoured him with his particular confidence. In 1761, he was ordered on ſervice in the light troops under General Berg; and with the rank of a field officer (we think that of Lieutenant-colonel) he performed prodigies of valour, and exhibited much of that character which was afterwards ſo fully developed and diſplayed. Even then he ſeems to have formed the reſolution of dying on the field of battle rather than ſuffer himſelf to be taken priſoner; for when, with a handful of troops, he was once ſurrounded by a large detachment of Pruſſians, he determined to cut his way through them, or periſh in the attempt. In this daring enterpriſe he was not only ſuccefsful, but contrived to carry off with him twenty priſoners, though he was obliged to abandon two field-pieces, which he had a little before taken from a ſmaller detachment.

At the peace of 1762, he received from the Empreſs a colonel's commiſſion, written with her own hand; and being advanced, in 1768, to the rank of brigadier, he was, in the month of November, ordered to repair, with all poſſible ſpeed, to the frontiers of Poland. At that unfavourable ſeaſon, he croſſed rivers and moraſſes, whoſe paſſage was rendered more difficult by ſlight froſts: and, in the courſe of a month, traverſed 500 Engliſh miles, with the loſs of only a few men in the environs of Smolenſko.

The object of the Empreſs, at this time, was to ſubdue the Poliſh confederates, and to poſſeſs herſelf of certain provinces of that ill-fated kingdom. How completely ſhe and her two allies, the Emperor of Germany and the King of Pruſſia, ſucceeded in their enterpriſe, has been related elſewhere (ſee Poland, *Encycl.*). It is ſufficient, in this memoir, to obſerve, that the ſucceſſes of the Ruſſians were chiefly owing to the military ſkill and intrepidity of Suworow, who was their only active General, and was indeed, for four years, almoſt conſtantly employed in offenſive operations againſt

(a) This name is ſpelled ſometimes as we have ſpelled it, ſometimes Suwarrow, and ſometimes Suvoroff. This laſt is according to the pronunciation; but we have adopted the orthography of the General himſelf, in his letter to Charette, the hero of Vendee.

Suworow. againſt the confederates. Not to mention the numerous actions and ſkirmiſhes of an inferior kind, in which his conduct and courage were always diſplayed, the victory at Staloviz, over a ſuperior force, ably commanded, and the capture of Cracow, were alone ſufficient to intitle him to the character which he ever afterwards ſo well ſupported. The former of theſe drew the higheſt encomiums from the great Frederick of Pruſſia; and the latter decided the fate of Poland. It is proper to add, that Suworow, on theſe occaſions, did not tarniſh his laurels by unneceſſary cruelty. When a French officer, who ſurrendered at Cracow, offered him his ſword, according to the cuſtom of war, he refuſed it, ſaying, that he would not take the ſword of a brave man, whoſe maſter was not at war with his ſovereign; and, even to the leaders of the confederates, he granted better terms of capitulation than they had the preſumption to aſk.

In the year 1770, he had been promoted to the rank of Major general; and for his exploits in the Poliſh war, the Empreſs conferred upon him at different times, the orders of St Ann, St George, and Alexander Newſky.

After performing ſome important ſervices on the frontiers of Sweden, Suworow received orders in the beginning of 1773, to join the army in Moldavia, under the command of Field-marſhal Romanzow; and there he began that glorious career, which ſoon made his name a terror to the Turks. His firſt exploit was the taking of Turtukey; of which he wrote the following laconic account to the commander in chief:

"Honour and glory to God! Glory to you, Romanzow! We are in poſſeſſion of Turtukey, and I am in it! "Suworow."

During the remainder of the war, which was of ſhort continuance, Suworow was conſtantly engaged, and conſtantly ſucceſsful. In the beginning of the year 1774, he was promoted to the rank of Lieutenant-general; and on the 11th of June of the ſame year, he defeated the Turks in a great battle, in which they loſt 3000 men killed, ſome hundreds of priſoners, 40 pieces of artillery, and 80 ſtandards, with their ſuperb camp. Soon after this victory, peace was concluded between the two courts; and Lieutenant-general Suworow was ordered to proceed with all poſſible haſte to Moſcow, to aſſiſt in appeaſing the interior troubles of that part of the empire.

Theſe troubles were occaſioned by a Coſſac rebel, of the name of *Pugatchew*, or *Pugatcheff*, who, at the head of a party of his diſcontented countrymen, had long eluded the vigilance of Count Panin, the commander in chief in Muſcovy, and frequently cut off detachments of the army which were ſent out in queſt of him. The chace of Pugatcheff, for ſuch it may be called, was now wholly entruſted to the well-known activity of Suworow; and that General, after purſuing the rebel with inconceivable rapidity, through woods and deſerts, came up with him at a place called Urlaſk, and carried him priſoner to Count Panin, who ſent him to Moſcow, where he ſuffered the puniſhment due to his crimes. This inſurgent, it is ſaid, had at one time collected ſuch a force, and was followed with ſuch enthuſiaſm, that, if his underſtanding had been equal to his courage, and his moderation had kept pace with his power, he might have poſſeſſed himſelf of Moſcow, and made the Imperial Catharine tremble on her throne.

For ſeveral years after the taking of Pugatcheff, Suworow was employed in the Crimea, on the Cuban, and againſt the Nogay Tartars, in a kind of ſervice which, though it was of the utmoſt importance to the Empreſs, and required all the addreſs of the Lieutenant-general, furniſhed no opportunities for that wonderful diſplay of promptitude and reſource which had characteriſed his more active campaigns. One incident, however, muſt be mentioned, even in this ſhort memoir, becauſe it ſhews the natural diſpoſition of the man. During the winter that Suworow paſſed among the Tartars, he was frequently viſited by the chiefs of that nation; and at one of theſe viſits, Mechmed Bey, the chief of the Gediſſens, often joked with Muſſa Bey, another chief, on his inclination to marry. Muſſa Bey was ſo extremely old, that Suworow thought the converſation ridiculous; and one day aſked him, What ground Mechmed could have for ſuch idle talk? Muſſa replied, that Mechmed Bey was right; that he wiſhed to marry; and that he hoped the General would make him a preſent of a beautiful Tartar girl of ſixteen! Suworow immediately bought a young Tartar ſlave of a Coſſac for 100 rubles, and ſent her to Muſſa Bey; who married her, lived with her a very few years, and died at the age of one hundred and eight! regretted, we are told, by the Lieutenant-general, who regarded him with great eſteem and attachment.

In the end of the year 1786, Suworow was promoted to the rank of General in Chief; and, at the breaking out of the war with the Turks in 1787, he ſhewed how well he was intitled to that rank, by his maſterly defence of Kinburn; a place of no ſtrength, but of great importance, as it is ſituated at the mouth of the Dneiper, oppoſite to Oczakow. For the zeal and abilities which he diſplayed on this occaſion, the Empreſs decorated him with the order of St Andrew; gave him ſix croſſes of the order of St George, to be diſtributed, according to his judgment, among ſuch of his officers as had moſt diſtinguiſhed themſelves; and, in a very flattering letter, regretted the wounds which he had received in defending the place.

At the ſiege of Oczakow, Suworow, who commanded the left wing of the army under Prince Potemkin, received a dangerous wound in the nape of the neck, which was followed by ſo ſmart a fever, that, for ſome time, his life was deſpaired of; but he perſevered in his long accuſtomed practice of preferring regimen to medicine, and his health was gradually re-eſtabliſhed. In the year 1789, he was appointed to the command of the army which was to co-operate with the Prince of Saxe Cobourg in Walachia; and, by marches of inconceivable rapidity, he twice, in the ſpace of two months, preſerved the army of that Prince from inevitable deſtruction. Putting himſelf at the head of 8000 Ruſſians, and literally running to the aid of his ally, he came up with the Turks in time to change the fate of the day at the battle of Forhani, which was fought on the 21ſt of July; and again at Rymnik, which, with 7000 men, he had reached with equal celerity, he gained, on the 22d of September, in conjunction with the Prince, one of the greateſt victories that have ever been atchieved. According to the leaſt exaggerated account, ow. count, the Turkish army, commanded by the Grand Visier in person, amounted to 90,000 or 100,000 men; of which 70,000 were chosen troops: whilst the army of the allies exceeded not 25,000. At the commencement of the attack, Suworow, who had reconnoitred the country, and formed the plan of the battle, called out to his Russians, "My friends, look not at the eyes of your enemies, but at their breasts; it is there that you must thrust your bayonets." No quarter was given to the Turks; and on this account the Russian General has been charged with savage ferocity: but the charge, if not groundless, must be shared equally between him and the Prince of Cobourg. The commanders of the allied army, aware of the immense superiority of their enemies, had resolved, before the engagement, not to encumber themselves with prisoners, whom they could not secure without more than hazarding the fate of the day: And where is the man, who admits the lawfulness of war, that will condemn such conduct in such critical circumstances?

The taking of Bender and Belgrade were the immediate consequences of the victory of Rymnik; and so sensible was the Emperor Joseph how much the rapid movements and military skill of Suworow had contributed to that victory, that he immediately created him a Count of the Roman empire, and accompanied the diploma with a very flattering letter. Similar honours were conferred upon him by his own sovereign, who sent him the diploma of Count of the empire of Russia, with the title of Rymnikski, and the order of St Andrew of the first class.

In the autumn of 1790, Prince Potemkin wrote to Count Suworow, requesting a particular conference. The General, who conjectured the object of it, sent him the following answer: "The flotilla of row-boats will get possession of the mouths of the Danube; Tulcia and Isaccia will fall into our power; our troops, supported by the vessels, will take Ismailow and Brahilow, and make Tchistow tremble." He was perfectly right in his conjecture: it was to concert with him measures for the taking of Ismailow that the Prince had requested the conference. He did not, however, receive orders to undertake that desperate enterprise till the beginning of November, when he rapidly approached towards that fortress. His army, by sea and land, consisted of 23,000 men; of whom one-half were Cossacs, and of these many were sick. The troops of the garrison, which were under the orders of seven Sultans, amounted to 43,000 men, of whom nearly one half were Janissaries; the fortress was by much the strongest of any on the Turkish frontier: it was under the command of an old warrior, who had twice refused the dignity of Grand Visier, and had displayed against the Austrians considerable abilities, as well as the most intrepid courage; and the Grand Seignior had published a firman, forbidding the garrison, on pain of death without trial, to surrender on any terms whatever.

Potemkin, knowing that Suworow had with him no battering cannon, and dreading the consequences of a repulse, wrote to the General, that if he was not certain of success, he would do well not to risk an assault. The laconic reply was; "My plan is fixed. The Russian army has already been twice at the gates of Ismailow; and it would be shameful to retreat from them the third time without entering the place." To spare the effusion of blood, however, if possible, he sent a note to the Seraskier who commanded in Ismailow, to assure him, upon Count Suworow's word of honour, that if he did not hang out a white flag that very day, the place would be taken by assault, and all the garrison put to the sword. The Seraskier returned no answer to the note; but another commander was pleased to say, that "The Danube would cease to flow, or the heavens bow down to the earth, before Ismailow would surrender to the Russians!"

Suworow.

Having concerted with the Admiral proper measures for the assault, Suworow passed the night, with some officers of his suite, in impatient vigilance for the appointed hour when the signals were to be given. These were the firing of a musket at three, four, and five in the morning, when the army rushed upon the place; and notwithstanding the desperate opposition of the Turks, the depth of the moat, and the height of the ramparts, they were completely masters of Ismailow by four o'clock P. M. In this one dreadful day the Ottomans lost 33,000 men killed or dangerously wounded; 10,000 who were taken prisoners; besides 6000 women and children, and 2000 Christians of Moldavia, who fell in the general massacre. The place was given up to plunder for three days, according to agreement with the army before the assault; but we have authority to say, that no person was murdered in cold blood, who did not prefer his property to his life.

The Russians found in Ismailow 232 pieces of cannon, many large and small magazines of gunpowder, an immense quantity of bombs and balls, 345 standards almost all stained with blood, provisions for the Turkish army for six months, and about 10,000 horses, of which many were extremely beautiful. Suworow, who was inaccessible to any views of private interest, did not appropriate to himself a single article, not so much as a horse; but having, according to his custom, rendered solemn thanks to God for his victory, wrote to Prince Potemkin the following Spartan letter: "The Russian colours wave on the ramparts of Ismailow."

Peace being concluded with the Turks in December 1791, no political events occurred from that period to call forth the military talents of Suworow till 1794. In the beginning of that year mutinies having broken out among the Polish troops in the service of Russia, and the Empress, with her two potent allies, having digested the plan for the partition of Poland, Count Suworow received orders, in the month of May, to proceed, by forced marches, into Red Russia, with a corps of 15,000 men, and to disarm all the Polish troops in that province. This service he performed without the effusion of blood, disarming in less than a fortnight 8000 men, dispersed over a country of 150 miles in circuit. Soon afterwards he was ordered to march into the interior of Poland; the King of Prussia having been obliged to raise the siege of Warsaw, and the Empress perceiving that more vigorous measures than had hitherto been pursued, were necessary to accomplish her designs.

To give a detailed account of his route to Warsaw, would be to write the history of the Polish war, and not the memoirs of Count Suworow. It has been rashly supposed, that he had to contend only with raw troops, commanded by inexperienced leaders, who were not cordially united among themselves; but the fact is

 otherwise,

Suworow. otherwife, and Suworow never difplayed greater refource in the day of danger, than in the numerous battles and fkirmifhes in which he was engaged on his march to the capital of Poland. At laft, after furmounting every obftacle, he fat down, on the 22d of October, before Praga, a ftrongly fortified fuburb of Warfaw, defended by a formidable artillery, and a garrifon of 30,000 men, rendered defperate by their fituation. The Ruffian army exceeded not 22,000; and with that comparatively fmall force he refolved to ftorm Praga, as he had ftormed Ifmail. Having erected fome batteries to deceive the garrifon into a belief that they were to be regularly befieged, he concerted with the other Generals the mode of affault; and when every thing was ready, he gave his orders in thefe words: "Storm, and take the batteries, and cut down all who refift; but fpare the inhabitants, unarmed perfons, and all who fhall afk for quarter."

There are but few examples of a military operation fo boldly conceived, fo fkilfully performed, or fo important in its confequences, as the taking of Praga. The affault was made at once in feven different places at five in the morning; and at nine the Ruffians were mafters of the place, having penetrated by pure force a triple entrenchment. Of the Poles 13,000 lay dead on the field of battle, one-third of whom were the flower of the youth of Warfaw; above 2000 were drowned in the Viftula; and 14,680 were taken prifoners, of whom 8000 were difarmed and immediately fet at liberty, and the remainder the next day. We mention thefe circumftances, becaufe they completely refute the tales of thofe Jacobin fcribblers, who have fo ftrenuoufly endeavoured to tarnifh the laurels of the Ruffian hero, by reprefenting him as having ordered a general maffacre of men, women, and children. The artillery taken from the enemy confifted of 104 pieces of cannon and mortars, chiefly of large calibre. The Ruffians had 580 men killed, of whom eight were fuperior and ftaff-officers, and 900 wounded, of whom 23 were officers.

Soon after the ftorming of Praga, Warfaw capitulated, and Suworow was received into the city by the magiftrates in a body, and in their ceremonial habits. When the prefident prefented to him the keys of the city, he preffed them to his lips, and then, holding them up towards heaven, he faid, "Almighty God, I render thee thanks, that I have not been compelled to purchafe the keys of this place as dear as . . . . ." Turning his face towards Praga, his voice failed him, and his cheeks were inftantly bathed with tears. As he rode through the ftreets, the windows were filled with fpectators, who were delighted with the return of order, and the affurance of peace; and the air refounded with the exulting exclamations of "Long live Catharine! Long live Suworow!"

Thus did Count Suworow, in the courfe of a very few months, overturn the kingdom and republic of Poland. It is not our bufinefs, in this article, to decide on the juftice of the caufe in which he was embarked. Of the Polifh revolution, which gave rife to the war that fubverted the republic, and fwept it from the number of fovereign ftates, the reader will find fome account under the title POLAND in the *Encyclopædia*; but it is here proper to acknowledge, that we do not now think fo favourably, as when we wrote that article, of the views and principles of thofe who framed the conftitution, which brought upon them the Ruffian and Pruffian arms. Subfequent events feem to have proved completely, that if Poland had not been conquered by the allied powers, it would foon have been involved, under Kofkiufko and his Jacobinical adherents, in all the horrors of revolutionary France; and the unhappy king, inftead of being carried captive into Ruffia, would probably have finifhed his courfe on a fcaffold. Suworow, who never concerned himfelf with the intrigues of courts, and expreffed on all occafions the moft fovereign contempt of thofe Generals who affected to poffefs the fecrets of ftatefmen, probably never enquired into the final object of the war, but thought it his duty to execute, in his own fphere, the orders of his Imperial miftrefs. So fenfible was Catharine of the propriety of this conduct, and of the zeal and abilities which he had difplayed in the Polifh campaign, that immediately on receiving accounts of the ftorming of Praga and the fubmiffion of Warfaw, fhe announced to him, in a letter written with her own hand, his well-earned advancement to the rank of Field-marfhal General. Nor did her munificence ftop there: She loaded him with jewels, and prefented him with an eftate of 7000 peafants, in the diftrict of Kubin, which had been the fcene of his firft battle in the courfe of the campaign.

From the fubjugation of Poland we hear little more of Field-marfhal Suworow till he entered upon his glorious career in Italy. He is faid, indeed, to have given offence to the Emperor Paul foon after his acceffion to the throne, by affording protection to fome meritorious officers, whom his Majefty had in an arbitrary manner difmiffed from the fervice; but that offence was overlooked, and Suworow called again into action, when Paul joined the coalition againft France.

Of the exploits of the Field-marfhal in Italy, where, to ufe his own words, he deftroyed armies and overturned ftates, we have given a full account under the title REVOLUTION in this *Supplement*. In his former campaigns, the wifdom of his meafures, the diftribution of his forces, the undaunted character of his operations, and the progreffive continuance of his fucceffes, furnifh proofs of the fuperiority of his talents hardly to be paralleled in the annals of modern war; but, animated by the noblenefs of his caufe, and confiding, as he faid, in the God of battles, he feems in his laft campaign to have furpaffed himfelf (B). It would appear, however, that

(B) Were any other proof than a fimple narrative of his fuccefs neceffary to evince the abilities difplayed by Marfhal Suworow in the laft campaign, that proof might be found in the fad reverfes of the prefent. At the opening of the campaign of 1800, the allies poffeffed infinitely greater advantages over the enemy than at the beginning of the campaign of 1799; and we ventured to fay, towards the end of the article REVOLUTION, in this *Supplement*, that the affairs of the French feemed in Italy to be defperate. But how egregioufly have we been miftaken? By the moft unaccountable infatuation, the Auftrian commander in Italy would not *believe* that the French army of referve, which was advancing upon him with the ufual celerity of the

Suworow. that his own Sovereign thought otherwise; and if he did, he was certainly as singular in that opinion as he is said to be in many others. Considering the Field-marshal as the conqueror of Italy, he had indeed created him a Prince by the style and title of Prince Suworow-*Italiski*; but how did he receive him, when he returned into the Russian dominions at the head of his veteran and victorious bands?

Though the old warrior thought himself almost betrayed at the end of the campaign by the crooked policy of the court of Vienna, he doubtless hoped to be received at the court of St Petersburg, if not with triumphal arches, at least with the most public testimonies of his Sovereign's approbation. It is said, that he expected to be sent back at the head of a large army, with full powers to act as he should judge proper for bringing the war to a happy termination, and restoring peace and order to Europe; and he certainly expressed, in letters to different correspondents, his earnest wish to conclude his military career with contributing to the accomplishment of so desirable an object. What then must have been his disappointment, when the Russian Emperor would not see him, and positively forbad his appearance at court? To the messenger who brought the order, the Field-marshal gave a purse of money, turned his carriage another way, and drove to a wooden house, at a distance from the court, and from his former friends, "where burst his mighty heart;" and the conqueror of the Turks, the Poles, and the French republicans, died, almost unattended, on the 18th of May 1800. The sovereign, who thus disgraced him at the end of his life, gave him a magnificent funeral! Suworow.

In his person Suworow was tall, considerably exceeding six feet, and full chested. His countenance was stern; but among his friends his manners were pleasant, and his dispositions were kind. His temper was naturally violent; but that violence he constantly laboured to moderate, though he was never able completely to extinguish it. According to M. Anthing, an effervescent spirit of impatience predominated in his character; and it perhaps never happened (says that author) that the execution of his orders equalled the rapidity of his wishes. Though he disliked all public entertainments, yet when circumstances led him to any of them, he appeared to partake, and endeavoured to promote, the general pleasure. Sometimes he condescended even to dance and play at cards, though very rarely, and merely that he might not interrupt the etiquette of public manners, to which, when not in the field, he was very attentive. In the field he may be said to have spent the whole of his life from the period at which he first joined the army in the seven years war; for during the time that he was not engaged in actual warfare, and that time, taken altogether, did not exceed twelve years, he was always placed at the head of armies stationed on the frontier of some enemy's country. He was therefore a mere warrior, and as such had no fixed habitation. With respect to his table and lodging, he contented

---

First Consul's movements, consisted of more than *six thousand men!* Instead therefore of marching rapidly to meet them before they could be wholly disentangled from the passes over the Alps, he waited patiently for them in the plains of Marengo. If we may judge of the future by the past, we may surely say that such would not have been the conduct of Suworow. Even after the two hostile armies met, and fought, on the 10th of July, one of the bloodiest battles of the present war, the success of the French was not such as to intitle them to the acquisitions which were the consequence of their dear-bought victory. The fate of the day was long doubtful; and it was at last decided, not by any extraordinary exertions of the Consul, but partly by the provident conduct of General Dessaix, who, with the aid of fresh troops, erected a new battery at a critical point, and at a critical period; and still more by the situation of General Melas, whose faculties, though frequently supported by wine and spirits, are said to have wholly forsaken him in the latter part of the day. When he was in this state, one false movement, which weakened his centre, afforded an opportunity to Dessaix to make a vigorous and successful charge with a body of cavalry that had not yet been engaged.

But even after this defeat, what was the state of the two armies? The Austrians had lost 9000 men, and the French from 12,000 to 14,000: the former, enraged at having had the victory so wrested out of their hands, were eager to renew the contest on the following day; and the latter had obtained only the barren advantage of keeping possession of the field of battle. In such a situation, Suworow would certainly have encouraged the ardour of his men; but the Austrian commander, who complained last year of the Field-marshal for being too little sparing of blood, instead of following the example which he had set him at the battle of Trebia, concluded a capitulation unparalleled, we believe, in the annals of war; a capitulation by which he voluntarily surrendered into the hands of the enemy nearly all the fruits of one of the most glorious campaigns recorded in history. We wish not to throw any undue aspersion upon the character of General Melas: We believe him to be a brave man, and such he has been represented to us in various accounts which we have had directly from Germany; but all these accounts agree in representing him likewise as fit, not to have the supreme command of a great army, but only to execute the orders of a superior mind.

In Germany, the gallant Kray has been obliged to retreat before the equally gallant Moreau; but he has wisely not hazarded the consequences of a general action. We say *wisely*; because we have learned from authority which we cannot question, that his army is in a state little better than that of mutiny. To his officers he is in a great measure a stranger; and therefore these gentlemen think themselves at liberty to disobey his orders! What the consequence of all this will be, it becomes not us to conjecture. An armistice has in the mean time* taken place both in Italy and in Germany; and it is not impossible that the Aulic Council, aided by the mob of Vienna, may induce the Emperor to make a separate peace.—Since this note was written the changes which have taken place are well known—and the peace which has at last been definitively concluded at Amiens, will at least give a respite to almost exhausted Europe.

* September the 4th 1800.

Suworow.

contented himſelf with whatever he found, requiring nothing but what abſolute neceſſity demands, and what might be tranſported with eaſe from one place to another. His couch conſiſted of a heap of freſh hay ſufficiently elevated, and ſcattered into conſiderable breadth, with a white ſheet ſpread over it, with a cuſhion for his pillow, and with a cloak for his coverlid. He has been repreſented as dirty (c); but the repreſentation is falſe. M. Anthing aſſures, that he was clean in his perſon, and that, when not on actual ſervice, he waſhed himſelf frequently during the courſe of the day. It is among the ſingular, though unimportant circumſtances of his life (ſays the ſame author), that, for the laſt twenty years, he had not made uſe of a looking-glaſs, or incumbered his perſon with either watch or money.

He was ſincerely religious; took every opportunity of attending the offices of public devotion; and has been known, on Sundays and feſtivals, to deliver lectures on piety to thoſe whom duty called to attend on him. We are told by an anonymous writer, in a miſcellany not very forward to praiſe ſuch men as Suworow, or indeed to praiſe piety in men of any deſcription, that chancing one evening to overhear a captain abridge the prayer which his duty required him to repeat at the guard, the Field-marſhal called out to him, "Thou unconſcionable, abominable, impious man, thou wouldſt cheat Heaven! Thou wouldſt, no doubt, cheat likewiſe the Empreſs and me! I ſhall diſmiſs thee." His regard for ſacred things is indeed very apparent in the elegant letter which, on the 1ſt of October 1795, he wrote to Charette, the hero of Vendee, whom he congratulates upon taking up arms to reſtore the temples of the God of his fathers. Alluding to this trait of his character, and to his deteſtation of Jacobiniſm under every form, a late writer in a moſt reſpectable miſcellany has well characterized him as the

"Foe to religion's foe; of Ruſſia's throne
The prop, th' avenger, and the pride in one;
Whoſe conquering arms, in bold defiance hurl'd,
Cruſhed the rude monſter of the weſtern world."

We have already, when we thought not that we ſhould ſo ſoon be called upon to write his life, obſerved, that he was a ſcholar, a man of ſcience, and a poet. M. Anthing aſſures us, that from his earlieſt years he was enamoured of the ſciences, and improved himſelf in them; but that as the military ſcience was the ſole object of his regard, thoſe authors of every nation who inveſtigate, illuſtrate, or improve it, engroſſed his literary leiſure. Hence Cornelius Nepos was with him a favourite claſſic; and he read, with great avidity and attention, the hiſtories of Montecuculi and Turenne. Cæſar, however, and Charles XII. (ſays the ſame author) were the heroes whom he moſt admired, and whoſe activity and courage became the favourite objects of his imitation.

With reſpect to his moral character, we have every reaſon to believe that he was a man of the moſt incorruptible probity, immoveable in his purpoſes, and inviolable in his promiſes; that the cruelties of which he has been accuſed were the cruelties of Potemkin, and that by thoſe who knew him he was conſidered as a man of unqueſtionable humanity. The love of his country, and the ambition to contend in arms for its glory, were the predominant paſſions of his active life; and to them, like the ancient Romans, he ſacrificed every inferior ſentiment, and conſecrated, without reſerve, all the powers of his body and mind. His military career was one long and uniform courſe of ſucceſs and triumph, produced by his enterpriſing courage and extraordinary preſence of mind; by his perſonal intrepidity and promptitude of execution; by the rapid and unparalleled movements of his armies; and by their perfect aſſurance of victory when fighting under his banners. Such was Alexander Baſilowitch Count Suworow. In the year 1774 he married a daughter of the General Prince Iwan Proſorowſki, by whom he had two children, now living: Natalia, married to General Count Nicolai Zubow; and Arcadius Count Suworow, a youth of great promiſe, who accompanied his father in his unparalleled march from Italy to Switzerland.

Swallow ‖ Swan.

SWALLOW *Iſland*, in the Pacific Ocean, S. lat. 10, E. long. from Paris, 162 30; diſcovered by Roggewins, 1722.—*Morſe.*

SWALLOW's-TAIL, in fortification, is a ſingle tenaille, which is narrower towards the place than towards the country.

SWAMSCOT, or *Great River*, to diſtinguiſh it from another much leſs, alſo called *Exeter River*, riſes in Cheſter, in New-Hampſhire, and after running through Sandown, Poplin, Brentwood, and a conſiderable part of Exeter, affording many excellent mill-ſeats, tumbles over a fall 20 or 30 rods in length, and meets the tide from Piſcataqua harbour, in the centre of the townſhip of Exeter. The ſmaller river riſes in Brentwood and joins Great river about a third of a mile above Exeter. Here are caught plenty of alewives and ſome oyſters. Swamſcot is the Indian name of Exeter.—*Morſe.*

SWAN (See ANAS, *Encycl.*). It is now aſcertained, beyond the poſſibility of doubt, that there are *black* ſwans, of equal ſize, and the ſame habitudes, with the common white ſwan of Britain. Theſe fowls have been ſeen chiefly in New Holland; and Captain Vancouver, when there, ſaw ſeveral of them in very ſtately attitudes, ſwimming on the water; and, when flying, diſcovering the under part of their wings and breaſts to be white. Black ſwans were likewiſe ſeen in New Holland by Governor Philips, Captain White, and by a Dutch navigator, ſo long ago as in 1697. Governor Philips deſcribes the black ſwan as a very noble bird, larger than the common ſwan, and equally beautiful in form. Mr White indeed ſays, that its ſize is not quite equal to that of the European ſwan; but both theſe authors agree with Captain Vancouver in mentioning ſome white feathers in its wings.

SWAN *Iſland*, in the Diſtrict of Maine, divides the waters of Kennebeck river, three miles from the Chops of Merry-Meeting Bay. It is 7 miles long, and has a navigable channel on both ſides, but that to the eaſt is moſtly uſed. It was the ſeat of the ſachem *Kenebis*. The river itſelf probably took its name from the race of Sagamores of the name of Kenebis.—*Morſe.*

SWAN-

(c) By the anonymous author of the life of Catharine II.

Swannano, || Swinton.

SWANNANO, the east head water of French Broad river, in Tennessee. Also the name of a settlement within about 60 miles of the Cherokee nation.—*ib.*

SWANNSBOROUGH, the chief town of Onslow county, Wilmington district, N. Carolina.—*ib.*

SWANSEY, a township in Cheshire county, New-Hampshire, adjoining Chesterfield on the E. 97 miles westerly of Portsmouth. It was incorporated in 1753, and contains 1157 inhabitants.—*ib.*

Swansey, a township in Bristol county, Massachusetts, containing 1784 inhabitants. It was incorporated in 1667, and lies 51 miles southerly of Boston.—*ib.*

SWANTON, a township of Vermont, Franklin county, on the E. bank of Lake Champlain, on the south side of Mischiscoui river. This township has a cedar swamp in the N. W. part of it, towards Hog Island. The Mischiscoui is navigable for the largest boats 7 miles, to the falls in this town.—*ib.*

SWANTOWN, in Kent county, Maryland, is about 3 miles S. easterly of Georgetown.—*ib.*

SWEDESBOROUGH, a small post-town of New-Jersey, Gloucester county, on Racoon Creek, 3 miles from its mouth, in Delaware river, 11 S. by W. of Woodbury, 17 N. by E. of Salem, and 20 southerly of Philadelphia.—*ib.*

SWEET SPRINGS, in Virginia, 30 miles E. by N. of Greenbriar, 93 west of Staunton, and 380 S. W. of Philadelphia. In the settlement around these springs, a post-office is kept.—*ib.*

SWETARA, or *Swatara*, a river of Pennsylvania, which falls into the Susquehannah from the N. E. about 7 miles S. E. of Harrisburg.—*ib.*

SWINTON (John), a very celebrated English antiquary, was a native of the county of Chester, the son of John Swinton of Bexton in that county, gent. He was born in 1703. The circumstances of his parents were probably not affluent, as he was entered at Oxford in the rank of a servitor at Wadham college. This was in October 1719. It may be presumed, that he recommended himself in that society by his talents and behaviour, as on June 30. 1723, he was elected a scholar on a Cheshire foundation in the college. In the December following, he took his first degree in arts. Before he became master of arts (which was on December 1. 1726), he had chosen the church for his profession, and was ordained deacon by the bishop of Oxford, May 30. 1725; and was afterwards admitted to priest's orders on May 28. 1727. He was not long without some preferment, being admitted to the rectory of St Peter le Bailey in Oxford (a living in the gift of the crown), under a sequestration, and instituted to it in February 1728. In June, the same year, he was elected a fellow of his college; but, desirous probably to take a wider view of the world, he accepted, not long after, the appointment of chaplain to the English factory at Leghorn, to which he had been chosen. In this situation he did not long enjoy his health; and leaving it on that account, he was at Florence in April 1733, where he attended Mr Coleman, the English envoy, in his last moments. Mr Swinton returned thro' Venice and Vienna; and, in company with some English gentlemen of fortune, visited Presburgh in Hungary, and was present at one of their assemblies.

Dic-ry.

It is possible that he had not quitted England in the summer of 1730, for he was elected a Fellow of the Royal Society in June that year, and admitted about three months later. It was probably while he was abroad that he was admitted into some foreign societies; namely, the academy *degli Apatisti* at Florence, and the *Etruscan Academy* of Cortona. On his return, he seems to have taken up his abode at Oxford, where he resided all the latter part of his life, and was for many years chaplain to the gaol in that city. It may be presumed that he married in 1743; it was then, at least, that he gave up his fellowship. In 1759 he became bachelor of divinity: in 1767, he was elected *Custos Archivorum*, or keeper of the university records: and, on April 4. 1777, he died; leaving no children. His wife survived till 1784, and both were buried, with a very short and plain inscription, in the chapel of Wadham college.

It remains to take notice of the most important monuments of a literary man's life, his publications. These were numerous and learned, but not of great magnitude. He published, 1. "De Linguæ Etruriæ Regalis vernacula Dissertatio," 4to, 19 pages, Oxon. 1738. 2. "A critical essay concerning the words Δαιμων and Δαιμονιον, occasioned by two late inquiries into the meaning of the demoniacs in the New Testament," 8vo, London, 1739. 3. "De priscis Romanorum literis dissertatio," 4to, 20 pages; Oxon. 1746. 4. "De Primogenio Etruscorum Alphabeto, dissertatio," Oxon. 1746. 5. "Inscriptiones Citieæ: sive in binas Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ. Accedit de nummis quibusdam Samaritanis et Phœniciis, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis, dissertatio," 4to, 87 pages, Oxon. 1750. 6. "Inscriptiones Citieæ: sive in binas alias Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ," 4to, 19 pages. 7. "De nummis quibusdam Samaritanis et Phœniciis, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis, dissertatio secunda," 4to, 36 pages. 8. "Metilia: sive de quinario Gentis Metiliæ, è nummis vetustis cæteroquin minimum notæ, dissertatio," 4to, 22 pages, Oxon. 1750. 9. Several dissertations published in the Philosophical Transactions of the Royal Society. As, "A dissertation upon a Parthian Coin; with characters on the reverse resembling those of the Palmyrenes," vol. xlix. p. 593. "Some remarks on a Parthian Coin, with a Greek and Parthian legend, never before published," vol. l. p. 16. "A dissertation upon the Phœnician numeral characters anciently used at Sidon," vol. l. p. 791. "In nummum Parthicum hactenus ineditum conjecturæ," vol. li. p. 683. "A dissertation upon a Samnite Denarius, never before published," vol. lii. p. 28. "An account of a subærated Denarius of the Plætorian family, adorned with an Etruscan inscription on the reverse, never before published or explained," vol. lxii. p. 60. "Observations upon five ancient Persian Coins, struck in Palestine or Phœnicia before the dissolution of the Persian empire," vol. lxii. p. 345. Other papers by him may be found in the general-index to the Philosophical Transactions. 10. A part of the Ancient Universal History, contained in the sixth and seventh volumes of that great work. The particulars of this piece of literary history were communicated by Dr Johnson to Mr Nichols, in a paper printed in the Gentleman's Magazine for December 1784, p. 892. The original of that paper, which affords a strong proof of the

Swinton.

the ſteady attachment of Johnſon to the intereſts of literature, has been, according to his deſire, depoſited in the Britiſh Muſeum. The letter is as follows:

"To Mr Nichols.

"The late learned Mr Swinton of Oxford having one day remarked, that one man, meaning, I ſuppoſe, no man but himſelf, could aſſign all the parts of the Univerſal Hiſtory to their proper authors, at the requeſt of Sir Robert Chambers, or of myſelf, gave the account which I now tranſmit to you in his own hand, being willing, that of ſo great a work the hiſtory ſhould be known, and that each writer ſhould receive his due proportion of praiſe from poſterity. I recommend to you to preſerve this ſcrap of literary intelligence, in Mr Swinton's own hand, or to depoſite it in the Muſeum, that the veracity of the account may never be doubted.—I am, Sir, your moſt humble ſervant,

Dec. 6, 1784. SAM. JOHNSON."

The paper alluded to, beſides ſpecifying ſome parts written by other perſons, aſſigns the following diviſions of the hiſtory to Mr Swinton himſelf. "The hiſtory of the Carthaginians, Numidians, Mauritanians, Gætulians, Garamantes, Melano-Gætulians, Nigritæ, Cyrenaica, Marmarica, the Regio Syrtica, Turks, Tartars, and Moguls, Indians, and Chineſe, a diſſertation on the peopling of America, and one on the independency of the Arabs.

In the year 1740, Mr Swinton was involved in a law-ſuit, in conſequence of a letter he had publiſhed. It appears from a paper of the time,* that a letter from the Rev. Mr Swinton, highly reflecting on Mr George Baker, having fallen into the hands of the latter, the court of King's Bench made the rule abſolute for an information againſt Mr Swinton. Theſe two gentlemen were alſo engaged for ſome time in a controverſy at Oxford; which took its riſe from a matter relative to Dr Thiſtlethwaite, ſome time warden of Wadham, which then attracted much attention. Mr Swinton had the manners, and ſome of the peculiarities, often ſeen in very recluſe ſcholars, which gave riſe to many whimſical ſtories. Among the reſt, there is one mentioned by Mr Boſwell, in the Life of Johnſon, as having happened in the year 1754. Johnſon was then on a viſit in the univerſity of Oxford. "About this time (he ſays) there had been an execution of two or three criminals at Oxford, on a Monday. Soon afterwards, one day at dinner, I was ſaying that Mr Swinton, the chaplain of the gaol, and alſo a frequent preacher before the univerſity, a learned man, but often thoughtleſs and abſent, preached the condemnation ſermon on repentance, before the convicts, on the preceding day, Sunday; and that, in the cloſe, he told his audience, that he ſhould give them the remainder of what he had to ſay on the ſubject the next Lord's day. Upon which, one of our company, a doctor of divinity, and a plain matter-of-fact man, by way of offering an apology for Mr Swinton, gravely remarked, that he had probably preached the ſame ſermon before the univerſity. Yes, Sir (ſays Johnſon); but the univerſity were not to be hanged the next morning!"

* *The Champions, or Evening Advertiſer*, June 17th 1740.

Swinton ‖ Sypomba.

SYDNEY, in Lincoln county, Diſtrict of Maine, is 37 miles from Pownalborough, 98 from Hallowell, and 203 from Boſton.—*Morse.*

SYPOMBA, an iſland on the coaſt of Brazil, in S. America, about 7 leagues N. E. of St John's Iſland, and N. W. from a range of iſlands which form the great Bay of Para.—*ib.*

T.

Taawirry, ‖ Tabaſco.

TAAWIRRY, one of the two ſmall iſlands within the reef of the iſland of Otaheite, in the South Pacific Ocean. Theſe iſlands have anchorage within the reef that ſurrounds them.—*Morse.*

TABAGO, an iſland in the bay of Panama, about 4 miles long, and 3 broad. It is mountainous, and abounds with fruit trees. N. lat. 7 50, W. long. 60 16.—*ib.*

TABASCO, an iſland in the S. W. part of the Gulf of Mexico, and at the bottom of the Gulf of Campeachy, is about 36 miles long, and about 7 broad; and on it is built the town of Tabaſco, in lat. 17 40 N. and long. 93 39 W. It is the capital of a rich province of its name, and is ſituated at the mouth of the river Grijalva, 90 miles E. of Eſpirito Santo, and 160 S. E. of Mexico. It is not large, but is well built, and is conſiderably enriched by a conſtant reſort of merchants and tradeſmen at Chriſtmas. The river Grijalva divides itſelf near the ſea into two branches, of which the weſtern falls into the river Tabaſco, which riſes in the mountains of Chiapa, and the other continues its courſe till within 4 leagues of the ſea, where it ſubdivides, and ſeparates the iſland from the continent. Near it are plains which abound with cattle and other animals, particularly the mountain cow, ſo called from its reſembling that creature, and feeding on a ſort of moſs found on the trees near great rivers.—*ib.*

Taboguilla ‖ Tacquet.

TABOGUILLA, or *Little Tabago*, in the bay of Panama, a ſmaller iſland than Tabago, and near it. The channel between them is narrow but good, through which ſhips paſs to Point Chama or Nata.—*ib.*

TABOOYAMANOO, a ſmall iſland in the South Pacific Ocean, ſubject to Huaheine, one of the Society Iſlands.—*ib.*

TACAMES, a bay on the coaſt of Peru, in lat. about 1 6 N. and 3 leagues to the N. E. of Point Galera.—*ib.*

TACHIFI *Point*, on the coaſt of New Mexico, is 18 miles from the town of Pomaro.—*ib.*

TACQUET (Andrew), a Jeſuit of Antwerp, who died in 1660. He was a moſt laborious and voluminous writer in mathematics. His works were collected, and printed at Antwerp, in one large volume in folio, 1669.

TADOUSAC, a small place in Lower Canada, at the mouth of the river Saguenay, or Sagaenai, on the north shore of the river St Lawrence. Here a considerable trade has been carried on with the Indians, they bringing their furs and exchanging them for European cloths, utensils and trinkets. It is 98 miles below Quebec. N. lat. 48, W. long. 67 35.—*Morse.*

TAENSA, a settlement in West-Florida, on the eastern channel of the great Mobile river, on a high bluff, and on the scite of an ancient Indian town, which is apparent from many artificial mounds of earth and other ruins. It is about 30 miles above Fort Conde, or city of Mobile, at the head of the bay. Here is a delightful and extensive prospect of some flourishing plantations. The inhabitants are mostly of French extraction, and are chiefly tenants. The *myrica inodora*, or wax-tree, grows here to the height of 9 or 10 feet, and produces excellent wax for candles.—*ib.*

TAGAPIPE, a castle erected on a point of land in the Bay of All Saints, in Brazil. It is pretty considerable, and adds greatly to the strength of St Salvadore.—*ib.*

TAGO, *Sant*, or *Tiago Point*, on the west coast of New-Mexico, is between Salagua and the White Rock. —*ib.*

TAHOORA, or *Tahoorowa*, one of the smallest of the Sandwich Islands, 3 leagues from the south-west part of Mowee. N. lat. 20 38, W. long. 156 33.—*ib.*

TALAHASOCHTE, a considerable town of the Seminole Indians, situated on the elevated east banks of the Little river St John, near the bay of Apalache, in the Gulf of Mexico, about 75 miles from the Alachua savanna. Here are near 30 habitations constructed of frame work, and covered with the bark of the cypress tree, after the mode of Cuscowilla, and a spacious and neat council-house. These Indians have large handsome canoes, which they form out of the trunks of cypress trees, some capacious enough to hold 20 or 30 warriors. In these they descend the river on trading and hunting expeditions on the sea-coast, islands, and keys, quite to the Point of Florida; and sometimes cross the Gulf and go to the Bahama Islands, and even to Cuba, and bring returns of spirituous liquors, coffee, sugar, and tobacco.—*ib.*

TALAPOOSEE, or *Tallapoose*, the great north-east branch of the Alabama or Mobile river, in Florida. It rises in the high lands near the Cherokees, and runs through the high country of the Oakfuskee tribes in a westwardly direction, and is full of rocks, falls, and shoals, until it reaches the Tuckabatches, where it becomes deep and quiet; from thence the course is west about 30 miles to Little Tallasie, where it unites with the Coosa, or Coosa Hatcha. At Coolsome, near Otasse, a Muscogulge town, this river is 300 yards broad, and about 15 or 20 feet deep. The water is clear and salubrious. In most maps the lower part of this river is called *Oakfuskie.*—*ib.*

TALASSEE, or *Tallassee*, a county consisting of a tract of land bounded by East-Florida on the south, from which the head water of St Mary's river partly separates it; north by Alatamaha river, east by Glynn and Camden counties, and westerly by a line which extends from the western part of Ekanfanoka Swamp, in a N. E. direction till it strikes the Alatamaha river, at the mouth of the Oakmulgee. It is said that the State of Georgia had extinguished the Indian claim to this tract of land, but it has been given up to the Indians as the price of peace; for which that State makes a claim for 50,000l. with interest, since the treaty, upon the United States.—*ib.*

TALASSEE, a town of the Upper Creeks, in the Georgia western territory, on the south side of Talapoose river, distant about 3 days journey from Apalachicola on Chata Uche river. It is also called Big Talassee.—*ib.*

TALBERT's *Island*, on the coast of Georgia, the north point of which is in lat. about 30 44 N. where St Mary's river empties into the ocean between this island and Amelia Island on the N.—*ib.*

TALBOT, an island on the coast of East-Florida. The sands at the entrance of Nassau lie three miles off the south-east point of Amelia Island, and from the N. E. point of Talbot Island.—*ib.*

TALBOT, a county of Maryland, on the eastern shore of Chesapeak Bay, bounded E. by Choptank river, which divides it from Caroline county, and south by the same river, which separates it from Dorcester. It contains 13.084 inhabitants, of whom 4,777 are slaves. The soil is rich and fertile.—*ib.*

TALCAGUAMA, a cape on the coast of Chili, 11 leagues N. E. of the island of St Mary, and 2 northward of Port St Vincent.—*ib.*

TALCAGUAMA *Port*, is 6 miles within the above point of its name, and is one of two good roads in the bay of Conception.—*ib.*

TALLOW *Point*, a mark for anchoring in the harbour of Port Royal, on the south coast of the island of Jamaica.—*ib.*

TALLOW-TREE. See CROTON (*Encycl.*), where, however, we have fallen into a mistake, which it is here our duty to correct. We learn from Sir George Staunton, that the candles made of the vegetable tallow are firmer than those made of animal tallow, and free from all offensive smell, contrary to what was rashly said in the article referred to. They are not, however, equal to those of wax or spermaceti; but the latter of these substances is not within the reach of the Chinese, and the art of blanching the former is little known to them. The tallow tree is said to have been transplanted to Carolina, and to flourish there as well as in China.

TALOO *Harbour*, on the N. side of the island of Eimeo, in the South Pacific Ocean. S. lat. 17 30, W. long. 150.—*Morse.*

TALOOK, an Arabic word, which signifies literally attachment, connection, dependence. In Bengal, however, where it occurs perpetually in the enumeration of the districts and subdivisions of that province contained in the institutes of Akber, it signifies a tenure of land. Hence the *talook* of Cashinat, the *talook* of Meheys the headman, the *talook* of Ahmed Khan, &c. See *A Dissertation concerning the Landed Property of Bengal*, by Sir Charles Rouse Boughton.

TALOOKDAR, the possessor of a talook.

TALOOKDARY, tenure of a talookdar.

TALUS, or TALUD, in architecture, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height, to make it the firmer.

TALUS, in fortification, means also the slope of a work, whether of earth or masonry.

TAMALEQUE, an inland city, in the province of St Martha, on the coast of Terra Firma. It is situated on the banks of Magdalena river, and carries on a trade on that river from New Granada to Carthagena, from whence it is distant above 150 miles.—*Morse.*

TAMAR, *Cape*, is the N. W. point of a large bay and harbour on the N. shore of the Straits of Magellan, within the cape. The south east point of the bay is named Providence. S. lat. 52 51, W. long. 75 40. —*ib.*

TAMARIKA, an island on the coast of Brazil, northward of Pernambuco, and about 24 miles in length. It is 2 miles N. of Pornovello, and has a harbour and good fresh water. S. lat. 7 56, W. long. 35 5.—*ib.*

TAMASCAL, the name given in California to a kind of sand bath employed by the natives in the cure of the venereal disease. It is prepared by scooping a trench in the sand, two feet wide, one foot deep, and of a length proportioned to the size of the patient; a fire is then made through the whole extent of it, as well as upon the sand which was dug out of the hollow. When the whole is thoroughly heated, the fire is removed, and the sand stirred about, that the warmth may be equally diffused. The sick person is then stripped, laid down in the trench, and covered up to his chin with heated sand. In this position a very profuse sweat soon breaks out, which gradually diminishes according as the sand cools. The patient then rises and bathes in the sea, or the nearest river. This process is repeated till a complete cure is obtained. While the patient is undergoing the operation of the tamascal, he drinks a considerable quantity of a warm sudorific, prepared by the decoction of certain herbs, chiefly of the shrub called by the Spaniards GOUVERNANTE, which see in this *Supplement*.

TAMATAMQUE, called by the Spaniards, *Villa de las Palmas*, a town of Santa Martha, in Terra Firma, S. America; situated on the eastern bank of Santa Martha river, about 28 miles above Teneriffe.—*Morse.*

TAMBO *Land*, on the coast of Peru, extends about 9 miles from Cape Remate to Playa de los Perdrices, or the Partridge Strand, about 9 miles. There is clear and good anchorage upon this strand, under a row of high, ridgy, and sandy hills. On making them from the sea, they resemble a covey of partridges just rising; hence the name of the coast.—*ib.*

TAMMANY's, *St*, a village on Dan river, in Virginia, 15 miles from Gill's Bridge, 7 from Mecklenburg court-house, 42 from Halifax court-house, in North-Carolina, and 398 from Philadelphia.—*ib.*

TAMMANY, *Fort St*, or *St Mary's*, at the mouth of St Mary's river, on the S. line of Georgia.—*ib.*

TAMMATA-PAPPA, a low island of the N. Pacific Ocean, said to be near the Sandwich Islands.—*ib.*

TAMOU *Island*, one of the small islets which form part of the reef on the E. side of Ulietea Island, one of the Society Islands.—*ib.*

TAMWORTH, a township in the northern part of Strafford county, New-Hampshire. It was incorporated in 1766, and contains 266 inhabitants.—*ib.*

TAN is a substance found in most vegetables, which, not having hitherto been resolved into component parts, is therefore considered as simple. See *Vegetable and Animal SUBSTANCES* in this *Suppl.*

TANBANTY *Bay*, on the coast of Brazil, has a good road, sheltered by the sands that lie off within 3 miles of the shore. It is one of those places between Point Negro and Point Lucna.—*Morse.*

TANEYTOWN, a small post-town of Maryland, in Frederick county, between Piney Run and Pine Creek, on which are a number of mills and some iron-works. It lies 27 miles N. by E. of Frederickstown, and 121 W. S. W. of Philadelphia.—*ib.*

TANELA, or *Tonela*, a tract of shore on the west coast of Mexico, on the N. Pacific Ocean, commencing near the Sugar Loaf Hill, about 6 miles within the land, bearing N. E. and S. W. with the burning mountain of Lacatecolula, about 18 miles up the river Limpa —*ib.*

TANGOLA, an island in the N. Pacific Ocean, and on the west coast of New Mexico; affording good anchorage and plenty of wood and water. It is about 60 miles westward of Guatimala. It is also named *Tangolatango* —*ib.*

TANGUEY, or *Tonguey*, on the coast of Chili, in the S. Pacific Ocean, is 30 miles from Limari, and in lat. 30 30 S —*ib.*

TANNING is an art, of which a full account, according to the general practice in London and its vicinity, has been given under the proper title in the *Encyclopædia*. But since that article was written, the superior knowledge which has been obtained of the tanning principle, as well as of the composition of the skins of animals (See *Vegetable and Animal SUBSTANCES*, *Suppl.*), has suggested to scientific artists various methods of shortening the process by which leather is manufactured. M. Seguin is said to have thrown much light upon the art of the tanner as it is practised in France; and in 1795 Mr William Desmond obtained a patent for practising Seguin's method in England. He obtains the tanning principle by digesting oak-bark, or other proper material, in cold water, in an apparatus nearly similar to that used in the saltpetre works. That is to say, the water which has remained upon the powdered bark for a certain time, in one vessel, is drawn off by a cock, and poured upon fresh tan. This is again to be drawn off, and poured upon other fresh tan; and in this way the process is to be continued to the fifth vessel. The liquor is then highly coloured, and marks, as Mr Desmond says, from six to eight degrees on the hydrometer for salts. He calls this the tanning lixivium. The criterion to distinguish its presence is, that it precipitates glue from its aqueous solution, and is also useful to examine how far other vegetable substances, as well as oak bark, may be suitable to the purpose of tanning. The strong tanning liquor is to be kept by itself. It is found by trials with the glue, that the tanning principle of the first digester which receives the clear water, is, of course, first exhausted. But the same tan will still give a certain portion of the astringent principle, or gallic lixivium, to water. The presence of this principle is ascertained by its striking a black colour when added to a small quantity of the solution of vitriol of iron or green copperas. As soon as the water from the digester ceases to exhibit this sign, the tan is exhausted, and must be replaced with new. The gallic lixivium is reserved for the purpose of taking the hair off from hides.

Strong hides, after washing, cleaning, and fleshing, in in the usual way, are to be immersed for two or three days in a mixture of gallic lixivium and one thousandth part by measure of dense vitriolic acid. By this means the hair is detached from the hides, so that it may be scraped off with a round knife. When swelling or raising is required, the hides are to be immersed for ten or twelve hours in another vat filled with water and one five-hundredth part of the same vitriolic acid. The hides being then repeatedly washed and dressed, are ready for tanning; for which purpose they are to be immersed for some hours in a weak tanning lixivium of only one or two degrees; to obtain which, the latter portions of the infusions are set apart; or else some of that which has been partly exhausted by use in tanning. The hides are then to be put into a stronger lixivium, where in a few days they will be brought to the same degree of saturation with the liquor in which they are immersed. The strength of the liquor will by this means be considerably diminished, and must therefore be renewed. When the hides are by this means completely saturated, that is to say, perfectly tanned, they are to be removed, and slowly dried in the shade.

Calf skins, goat-skins, and the like, are to be steeped in lime-water after the usual fleshing and washing. These are to remain in the lime water, which contains more lime than it can dissolve, and requires to be stirred several times a day. After two or three days, the skins are to be removed, and perfectly cleared of their lime by washing and pressing in water. The tanning process is then to be accomplished in the same manner as for the strong hides, but the lixivium must be considerably weaker. Mr Desmond remarks, that lime is used instead of the gallic lixivium for such hides as are required to have a close grain; because the acid mixed with that lixivium always swells the skins more or less; but that it cannot with the same convenience be used with thick skins, on account of the considerable labour required to clear them of the lime; any part of which, if left, would render them harsh and liable to crack. He recommends, likewise, as the best method to bring the whole surface of the hides in contact with the lixivium, that they should be suspended vertically in the fluid by means of transverse rods or bars, at such a distance as not to touch each other. By this practice much of the labour of turning and handling may be saved.

Mr Desmond concludes his specification, by observing, that in some cases it will be expedient to mix fresh tan with the lixivium; and that various modifications of strength, and other circumstances, will present themselves to the operator. He affirms that, in addition to the great saving of time and labour in this method, the leather, being more completely tanned, will weigh heavier, wear better, and be less susceptible of moisture than leather tanned in the usual way; that cords, ropes, and cables, made of hemp or speartery, impregnated with the tanning principle, will support much greater weights without breaking, be less liable to be worn out by friction, and will run more smoothly on pulleys; insomuch that, in his opinion, it will render the use of tar in many cases, particularly in the rigging of ships, unnecessary; and, lastly, that it may be substituted for the preservation of animal food instead of salt.

Mr Nicholson, from whose Philosophical Journal we have taken this account of Mr Desmond's method of tanning, made some very proper enquiries at one of the first manufacturing houses in the borough of Southwark, concerning its value. He was told by one of the partners, that the principle upon which the new process is founded had been long known to them; but that they preferred the old and slower method, because the hides are found to feed and improve in their quality by remaining in the pit. He could gain no satisfactory information of what is meant by this feeding and improving; and, without taking upon us to decide between the advantages peculiar to Desmond's method and those of the common practice, we cannot help saying that this objection of the tanner at Southwark appears to us to be that of a man who either understands not the principles of his own art, or has some reason for opposing the progress of improvement, if it do not originate in his own house.

TANSA, a branch of the river Mobile, 3 leagues below the Alabama branch.—*Morse.*

TAOO, the most southerly of the Friendly Islands, in the South Pacific Ocean, is about 10 leagues in circuit, and so elevated as to be seen at the distance of 12 leagues.—*ib.*

TAOUKA, an island in the S. Pacific Ocean, one of the Society Islands. S. lat. 14 50, W. long. 145 9.—*ib.*

TAPANATEPEQUE, a town of Guaxaca, and audience of Mexico. It stands at the foot of the mountains Quelenos, at the bottom of a bay in the South Sea; and is represented as one of the pleasantest places in this country, and the best furnished with flesh, fowl and fish, being contiguous both to the sea and a river, amidst rich farms, each of which being stocked with between 1000 and 4000 head of cattle. Here are delightful walks of orange, lemon, citron, fig and other fruit trees.—*ib.*

TAPARICA, a long island on the west side of the entrance into the Bay of All Saints, in Brazil.—*ib.*

TAPAYO, a town of S. America, on the south bank of Amazon river, easterly from the mouth of Madeira river.—*ib.*

TAPPAHANNOCK, a post-town and port of entry of Virginia, in Essex county, between Dangerfield on the north and Hoskin's creek on the south, and on the south-west bank of Rappahannock river, 54 miles from Richmond, 67 from Williamsburg, and 263 from Philadelphia. It is also called *Hobbes' Hole.* It is laid out regularly, on a rich plain, and contains about 100 houses, an episcopal church, a court-house, and gaol; but is rather unhealthy. The exports for one year, ending Sept. 30, 1794, amounted to the value of 162,673 dollars.—*ib.*

TAPPAN, a town of New-York, in the south-east part of Orange county, about 4 miles from the north bank of Hudson's river, and at the south end of the Tappan sea. Here is a reformed Protestant Dutch church. Major Andre, adjutant-general of the British army suffered here as a spy, Oct. 2, 1780; having been taken on his way to New-York, after concerting a plan with major-general Arnold for the delivering up West Point to the British.—*ib.*

TAPPAN *Sea*, or *Bay*, a dilatation of Hudson's river, in the State of New-York, opposite the town of Tappan, and 35 miles north of New-York city; immediately south of and adjoining Haverstraw Bay. It is 10 miles long and 4 wide; and has on the north side

 fine

fine quarries of a reddish free-stone, used for buildings and grave-stones; which are a source of great wealth to the proprietors.—*ib.*

TAPUYES, or *Tapayos*, the most considerable nation of the native Brazilians, in S. America, that have not yet been conquered by the Portuguese. They spread themselves a great way inland to the west, and are divided into a great number of tribes or cantons, all governed by their own kings.—*ib.*

TARAHUMARY, a province of New Spain, 1200 miles distant from the capital.—*ib.*

TARBOROUGH, a post-town of N. Carolina; situated on the west side of Tar river, about 85 miles from its mouth, 140 from Ocrecock Inlet, 110 north by east of Fayetteville, 37 south of Halifax, 112 south by west of Petersburg in Virginia, and 420 south-west of Philadelphia. It contains about 50 houses, a court-house and gaol. Large quantities of tobacco, of the Petersburg quality, pork, beef, and Indian corn are collected here for exportation.—*ib.*

TARIJA, or *Chichas*, one of the fourteen jurisdictions belonging to the archbishopric of Plata, in Peru. It lies about 90 miles south of Plata; and its greatest extent being about 105 miles. The temperature of the air is various: in some parts hot, and in others cold; so that it has the advantage of corn, fruits and cattle. This country abounds every where in mines of gold and silver; but especially that part called Chocayas. Between this province and the country inhabited by the wild Indians, runs the large river Tipuanys, the sands of which being mixed with gold, are washed, in order to separate the grains of that metal.—*ib.*

TAR, or *Pamlico River*, a considerable river of N. Carolina, which pursues a south-east course, and passing by Washington, Tarborough and Greenville, enters Pamlico Sound in lat. 35 22 N. It is navigable for vessels drawing 9 feet water to the town of Washington, 40 miles from its mouth; and for scows or flats carrying 30 or 40 hhds. 50 miles farther to the town of Tarborough. According to the report of a committee, appointed by the legislature of N. Carolina, to inquire into the practicability of improving the inland navigation of the State, it is supposed that this river, and Fishy Creek, a branch of it, may be made navigable 40 miles above Tarborough.—*ib.*

TARPAULIN *Cove*, on the coast of Massachusetts, lies about 3 leagues N. N. W. of Holmes's Hole, in Martha's Vineyard. It is high water here, at full and change, two minutes after 10 o'clock; 5 fathoms water.—*ib.*

TARRYTOWN, a considerable village in Phillips's Manor, New-York, on the east side of Hudson's river, 30 miles N. of New-York city. Under a large tree, which is shewn to travellers as they pass the river, is the spot where the unfortunate Major Andre was taken; who was afterwards executed at Tappan.—*ib.*

TARTE's *Rapids*, *La*, on the river Ohio, lie 40 miles above the mouth of the Great Kanhaway.—*ib.*

TASSIE (James) modeller, whose history is intimately connected with a branch of the fine arts in Britain, was born in the neighbourhood of Glasgow of obscure parents; and began his life as a country stone mason, without the expectation of ever rising higher. Going to Glasgow on a fair day, to enjoy himself with his companions, at the time when the Foulis's were attempting to establish an academy for the fine arts in that city, he saw their collection of paintings, and felt an irresistible impulse to become a painter. He removed to Glasgow; and in the academy acquired a knowledge of drawing, which unfolded and improved his natural taste. He was frugal, industrious, and persevering; but he was poor, and was under the necessity of devoting himself to stone-cutting for his support: not without the hopes that he might one day be a statuary if he could not be a painter. Resorting to Dublin for employment, he became known to Dr Quin, who was amusing himself in his leisure hours with endeavouring to imitate the precious stones in coloured pastes, and take accurate impressions of the engravings that were on them.

That art was known to the ancients; and many specimens from them are now in the cabinets of the curious. It seems to have been lost in the middle ages; was revived in Italy under Leo X. and the Medici family at Florence; became more perfect in France under the regency of the Duke of Orleans, by his labours and those of Homberg. By those whom they instructed as assistants in the laboratory it continued to be practised in Paris, and was carried to Rome. Their art was kept a secret, and their collections were small. It is owing to Quin and to Tassie that it has been carried to such high perfection in Britain, and attracted the attention of Europe.

Dr Quin, in looking out for an assistant, soon discovered Tassie to be one in whom he could place perfect confidence. He was endowed with fine taste: he was modest and unassuming: he was patient; and possessed the highest integrity. The Doctor committed his laboratory and experiments to his care. The associates were fully successful; and found themselves able to imitate all the gems, and take accurate impressions of the engravings.

As the Doctor had followed the subject only for his amusement, when the discovery was completed, he encouraged Mr Tassie to repair to London, and to devote himself to the preparation and sale of those pastes as his profession.

In 1766 he arrived in the Capital. But he was diffident and modest to excess; very unfit to introduce himself to the attention of persons of rank and of affluence: besides, the number of engraved gems in Britain was small; and those few were little noticed. He long struggled under difficulties which would have discouraged any one who was not possessed of the greatest patience, and the warmest attachment to the subject. He gradually emerged from obscurity, obtained competence; and what to him was much more, he was able to increase his collection, and add higher degrees of perfection to his art. His name soon became respected, and the first cabinets in Europe were open for his use; and he uniformly preserved the greatest attention to the exactness of the imitation and accuracy of the engraving, so that many of his pastes were sold on the Continent by the fraudulent for real gems. His fine taste led him to be peculiarly careful of the impression; and he uniformly destroyed those with which he was in the least dissatisfied. The art has been practised of late by others; and many thousands of pastes have been sold as Tassie's, which he would have considered as injurious to his fame. Of the fame of others he was not envious; for

for he uniformly spake with frankness in praise of those who executed them well, though they were endeavouring to rival himself.

To the ancient engravings he added a numerous collection of the most eminent modern ones; many of which approach in excellence of workmanship, if not in simplicity of design and chastity of expression, to the most celebrated of the ancient. Many years before he died he executed a commission for the late Empress of Russia, consisting of about 15,000 different engravings (See Gem, *Encycl.*). At his death, in 1799, they amounted to near 20,000; a collection of engravings unequalled in the world. Every lover of the fine arts must be sensible of the advantage of it for improvement in knowledge and in taste. The collection of Feloix at Paris consisted of 1800 articles; and that of Dehn at Rome of 2500.

For a number of years, Mr Tassie practised the modelling of portraits in wax, which he afterwards moulded and cast in paste. By this, the exact likeness of many eminent men of the present age will be transmitted to posterity as accurately as those of the philosophers and great men have been by the ancient statuaries. In taking likenesses he was, in general, uncommonly happy; and it is remarkable, that he believed there was a certain kind of inspiration (like that mentioned by the poets) necessary to give him full success. The writer of this article, in conversing with him repeatedly on the subject, always found him fully persuaded of it. He mentioned many instances in which he had been directed by it; and even some, in which, after he had laboured in vain to realize his ideas on the wax, he had been able, by a sudden flash of imagination, to please himself in the likeness several days after he had last seen the original.

He possessed also an uncommonly fine taste in architecture, and would have been eminent in that branch if he had followed it.

In private life Mr Tassie was universally esteemed for his uniform piety, and for the simplicity, the modesty, and benevolence, that shone in the whole of his character.

TASTELESS Earth (*agust erde*), the name given by Professor Trommsdorff to a new simple earth, which he discovered in the Saxon beryl. It is distinguished (he says) from other earths by the following properties: It is white, and totally insoluble in water. In a fresh state, when moistened with water, it is somewhat ductile. In the fire it becomes transparent and very hard, so as to scratch glass, but remains insipid and insoluble in water. The burnt earth dissolves very easily in acids, and produces with them peculiar salts; which are entirely devoid of taste; and hence he gave it the name of *tasteless earth*. Fixed alkalies do not dissolve this earth either in the dry or in the wet way; and it is equally insoluble with the carbonic acid and with caustic ammonia. It has a greater affinity to the oxalic than to other acids. Professor Trommsdorff informs us, that a full account of this earth, accompanied with an accurate description, by Dr Bernhardi, of the fossil in which it is found, will appear in the first part of the eighth volume of his *Journal of Pharmacy*.

TATMAGOUCHE, or *Tatamagouche*, a place in Nova Scotia, on a short bay which sets up southerly from the Straits of Northumberland; about 25 miles from Onslow, and 21 from the island of St John's. It has a very good road for vessels, and is known also under the name *Tatamaganabou*.—*Morse*.

TATNAM *Cape*, the eastern point of Haye's river, in Hudson's Bay. N. lat. 57 35, W. long. 91 30.—*ib.*

TATOO-E-TEE, an island in the S. Pacific Ocean, one of the Ingraham Isles, called by Capt. Ingraham, *Franklin*, and by Capt. Roberts, *Blake*. It lies 7 or 8 leagues W. by N. of Nooheeva.—*ib.*

TAUMACO, an island about 1250 leagues from Mexico, where De Quiros stayed ten days. One of the natives named above 60 islands round it. Some of the names follow, viz. Manicola, Chicayano, larger than Taumaco, and about 300 miles from it; Guatopo, 150 miles from Taumaco; Tucopia, at 100, where the country of Manicola lay. The natives had, in general, lank hair; some were white, with red hair; some mulattoes, with curled hair; and some woolly like negroes. De Quiros observes that in the bay of Philip and James, were many black stones, very heavy, some of which he carried to Mexico, and upon assaying them, they found silver.—*ib.*

TAUNTON, a river which empties into Narraganset Bay, at Tiverton, opposite the N. end of Rhode-Island. It is formed by several streams which rise in Plymouth county, Massachusetts. Its course is about 50 miles from N. E. to S. W. and it is navigable for small vessels to Taunton.—*ib.*

Taunton, a post-town of Massachusetts, and the capital of Bristol county, situated on the W. side of Taunton river, and contains 40 or 50 houses, compactly built, a church, court-house, gaol, and an academy, which was incorporated in 1792. It is 36 miles S. by E. of Boston, 21 E. of Providence, 21 northerly of Bedford, and 312 N. E. of Philadelphia. The township of Taunton was taken from Raynham, and incorporated in 1639, and contains 3,804 inhabitants. A slitting-mill was erected here in 1776, and for a considerable time the only one in Massachusetts, and was then the best ever built in America. The annual production of 3 mills now in this township is not less than 800 tons of iron; about 50 tons are cut, and 300 hammered into nails, and the remainder is wrought into spades and shovels; of which last article 200 dozen are rolled annually. Mr Samuel Leonard rolled the first shovel ever done in America. This invention reduces the price one half. Wire-drawing, and rolling sheet-iron for the tin manufacture, are executed here. There is also a manufactory of a species of ochre, found here, into a pigment of a dark yellow colour.—*ib.*

Taunton *Bay*, in the District of Maine, is six miles from Frenchman's Bay.—*ib.*

TAVERNIER *Key*, a small isle, one of the Tortugas, 2 miles from the S. W. end of Key Largo, and 5 N. E. of Old Matacombe. To the northward of this last island is a very good road.—*ib.*

TAWANDEE *Creek*, in Northumberland county, Pennsylvania, runs N. E. into the east branch of Susquehannah, 12 miles south east of Tioga Point.—*ib.*

TAWAS, an Indian tribe in the N. W. Territory, 18 miles up the Miami of the Lake. Another tribe of this name, inhabit higher up the same river, at a place called the Rapids.—*ib.*

TAWIXTWI, *The English*, or *Pique Town*, in the N. W. Territory, is situated on the N. W. bank of the Great

Great Miami, 35 miles below the 5 mile portage, to the Miami of the Lake, and 68 S. W. by S. of Miami Fort. It was taken in 1752, by the French. N. lat. 40 41, W. long. 84 48.—*ib.*

TEACHES, a ſmall iſland cloſe to the eaſt ſhore of Northampton county, Virginia, and N. by E. of Parramore Iſland.—*ib.*

TECOANTEPEC, or *Tecuantepeque*, or *Teguantepeque*, a large bay on the weſt coaſt of New-Mexico, on the ſouth ſide of the Iſthmus from the Bay or Gulf of Campeachy, in the S. W. part of the Gulf of Mexico; and bounded weſt by Point Angelos. The port town of its name, lies in lat. 15 28 N. and long. 96 15 W.—*ib.*

TEETH, of various ſorts of machines, as of mill wheels, &c. Theſe are often called cogs by the workmen; and by working in the pinions, rounds, or trundles, the wheels are made to turn one another. Mr Emerſon (in his Mechanics, prop. 25.) treats of the theory of teeth, and ſhews that they ought to have the figure of epicycloids, for properly working in one another.

TEHUACAN, a city of New-Spain, 120 miles S. E. of Mexico.—*Morse.*

TEKAWY, in Bengal, money advanced by government to the proprietors or cultivators of land to aſſiſt them under circumſtances of diſtreſs.

TEKY *Sound*, on the coaſt of Georgia, to the ſouth of Savannah river, is a capacious road, where a large fleet may anchor in from 10 to 14 fathoms water, and be land-locked, and have a ſafe entrance over the bar of the river. The flood tide is generally 7 feet.—*Morse.*

TELESCOPE, is an inſtrument which has been ſo completely deſcribed in the *Encyclopædia*, that it is introduced into this place merely to notice an ingenious ſuggeſtion of Mr Nicholſon's for improving the achromatic teleſcope, by adding an artificial iris to the object glaſs. Suppoſe (ſays he) a braſs ring to ſurround the object end of the teleſcope, and upon this let eight or more triangular ſlips of braſs be fixed, ſo as to revolve on equi-diſtant pins paſſing through each triangle near one of its corners. If the triangles be ſlided inwards upon each other, it may readily be apprehended that they will cloſe the aperture; and if they be all made to revolve or ſlide backwards alike, it is clear that their edges will leave an octagonal aperture, greater or leſs according to circumſtances. The equable motion of all the triangles may be produced either by pinions and one concave toothed wheel, or by what is called ſnail-work. Another kind of iris, more compact, may be made, by cauſing thin elaſtic ſlips of braſs to ſlide along parallel to the tube, and be conducted each through a ſlit in a braſs cap which ſhall lead them acroſs the aperture in a radical direction. It is probable alſo that the artiſt, who ſhall carry theſe hints into effect, may alſo think of ſeveral other methods.

This thought occurred to the author, from contemplating the contraction and dilatation of the iris of the eye, according as we look at an object more or leſs luminous. Theſe variations are ſo great, that in the obſervable variations of the human eye, the aperture is thirty times as large at one time as at another, whilſt in the cat the proportion is greater than a hundred to one.

TELICA, a burning mountain on the weſt coaſt of New-Mexico, ſeen at N. N. E. over the ridge of Toſta. It is one of the range of volcanoes which are ſeen along the coaſt from Fort St John's to Tecaantepeck, and is 18 miles from Volcano del Vejo, or Old Man's Burning Mountain; and there are two others between them, but not ſo eaſily diſcerned, as they do not often emit ſmoke.—*Morse.*

TELLICO *Block-Houſe*, in Tenneſſee, ſtands on the north bank of Tenneſſee river, immediately oppoſite the remains of Fort Loudon; and is computed to be 900 miles, according to the courſe of the river, from its mouth, and 32 miles ſouth of Knoxville in Tenneſſee. It was erected in 1794, and has proved a very advantageous military poſt. It has lately been eſtabliſhed, by the United States, as a trading poſt with the Indians.—*ib.*

TELLIGUO, *Great*, in the State of Tenneſſee, was ſituated on the eaſt ſide of the Chota branch of Tenneſſee river, about 25 miles N. E. of the mouth of Holſton river, and 5 ſouth of the line which marked Lord Granville's limits of Carolina. This was a Britiſh factory, eſtabliſhed after the treaty of Weſtminſter, in 1729.—*ib.*

TELLIGUO *Mountains*, lie ſouth of the above place, and ſeem to be part of what are now called the Great Iron Mountains, in the lateſt maps.—*ib.*

TEMPERAMENT OF THE SCALE OF MUSIC. I Introduction.

When the conſiderate reader reflects on the large and almoſt numberleſs diſſertations on this ſubject, by the moſt eminent philoſophers, mathematicians, and artiſts, both of ancient and modern times, and the important points which divided, and ſtill divide, their opinions, he will not ſurely expect, in a Work like our's, the deciſion of a queſtion which has hitherto eluded their reſearches. He will rather be diſpoſed, perhaps, to wonder how a ſubject of this nature ever acquired ſuch importance in the minds of perſons of acknowledged talents (for ſurely no perſon will refuſe this claim to Pythagoras, to Ariſtotle, Euclid, Ptolemy, Galileo, Wallis, Euler, and many others, who have written elaborate treatiſes on the ſubject); and his ſurpriſe will increaſe, when he knows that the treatiſes on the ſcale of muſic are as numerous and voluminous in China, without any appearance of their being borrowed from the ingenious and ſpeculative Greeks.

The ingenious, in all cultivated nations, have remarked the great influence of muſic; and they found no difficulty in perſuading the nations that it was a gift of the gods. Apollo and his ſacred choir are perhaps the moſt reſpectable inhabitants of the mythological heavens of the Greeks. Therefore all nations have conſidered muſic as a proper part of their religious worſhip. We doubt not but that they found it fit for exciting or ſupporting thoſe emotions and ſentiments which were ſuited to adoration, thanks, or petition. Nor would the Greeks have admitted muſic into their ſerious dramas, if they had not perceived that it heightened the effect. The ſame experience made them employ it as an aid to military enthuſiaſm; and it is recorded as one of the reſpectable accompliſhments of Epaminondas, that he had the muſical inſtructions of the firſt maſters, and was eminent as a performer.

Thus was the ſtudy of muſic ennobled, and recommended to the attention of the greateſt philoſophers. Its cultivation was held an object of national concern, and its profeſſors were not allowed to corrupt it in order

der to gratify the faſtidious taſte of the luxurious or the ſenſualiſt, who ſought from it nothing but amuſement. But its influence was not confined to theſe public purpoſes; and, while the men of ſpeculation found in muſic an inexhauſtible fund of employment for their genius and penetration, and their poets felt its aid in their compoſitions, it was hailed by perſons of all ranks as the ſoother of the cares and anxieties, and ſweetener of the labours of life. *O Phœbi decus!—laborum dulce lenimen.* Poor Ovid, the victim of what remained of good in the cold heart of Octavius, found its balm.

Exul eram (ſays he): *requieſque mihi, non fama petita eſt.*
Mens intenta ſuis ne foret uſque malis.
Hoc eſt cur cantet vinctus quoque compede foſſor,
Indocili numero cum grave mollit opus.
Cantet et innitens limoſæ pronus arenæ
Adverſo tardam qui trahit amne ratem,
Quique ferens pariter lentos ad pectora remos,
In numerum pulſâ brachia verſat aquâ.
Feſſus ut incubuit baculo, ſaxove reſedit
Paſtor; arundineo carmine mulcet oves.
Cantantis pariter, pariter data penſa trahentis
Fallitur ancillæ, decipiturque labor.

It is chiefly in this humble department of muſical influence that we propoſe at preſent to lend our aid. What has been ſaid in the article Music, *Encycl.* is ſufficient for informing the reader of what is received as the ſcale of muſic, and the inequality of its different ſteps, the tones major and minor, ſemitone, comma, &c. We ſhall only obſerve, that what is there delivered on temperament by M. d'Alembert, after Rameau, bears the evident mark of uncertainty or want of confidence in the principle adopted as the rule of temperament; and we have learned, ſince the printing of that article, that the inſtructions there delivered have not that perſpicuity and preciſion that are neceſſary for enabling a perſon to execute the temperament recommended by Rameau; that is, to tune a keyed inſtrument with certainty, according to that ſyſtem or conſtruction of the ſcale.

If ſuch be the caſe, we are in ſome meaſure diſappointed; becauſe we ſelected that treatiſe of D'Alembert as the performance of a man of great eminence as a mathematician and philoſopher, aiming at public inſtruction more than his own fame, by this elementary abſtract of the great work of the moſt eminent muſician in France.

To be able to tune a harpſichord with certainty and accuracy, ſeems an indiſpenſable qualification of any perſon worthy of the name of a *muſician.* It would certainly be thought an unpardonable deficiency in a violin performer if he could not tune his inſtrument; yet we are well informed, that many profeſſional performers on the harpſichord cannot do it, or cannot do it any other way than by uncertain and painful trial, and, as it were, groping in the dark; and that the tuning of harpſichords and organs is committed entirely to tuners by profeſſion. This is a great inconvenience to perſons reſiding in the country; and therefore many take leſſons from the profeſſed harpſichord tuners, who alſo profeſs to teach this art. We have been preſent during ſome of theſe leſſons; but it did not appear to us that the inſtructions were ſuch as could enable the ſcholar to tune an inſtrument when alone, unleſs the leſſons had been ſo frequent as to form the ear to an inſtantaneous judgment of tune by the ſame habit that had inſtructed the teacher. There ſeemed to be little principle that could be treaſured up and recollected when wanted.

Temperament of the Scale of Music.

3 Yet Nature furniſhes abundant means of doing this.

Yet we cannot help thinking that there are phenomena or facts in muſic, ſufficiently preciſe to furniſh principles of abſolute certainty for enabling us to produce temperaments of the ſcale which ſhall have determined characters, and among which we may chooſe ſuch a one as ſhall be preferable to the others, according to the purpoſes we have in view; and we think that theſe principles are of ſuch eaſy application, that any perſon, of a moderate ſenſibility to juſt intonation, may, without much knowledge or practice in muſic, tune his harpſichord with all deſirable accuracy. We propoſe to lay theſe before the reader. We might content ourſelves with ſimply giving the practical rules deduced from the principles; but it is ſurely more deſirable to perceive the validity of the principles. This will give us confidence in the deduced rules of practice. In the employment of ſacred muſic, an inſpired writer counſels us to ſing, not only "with the heart, but with the underſtanding alſo." We may, without irreverence, recommend the ſame thing here. Let us therefore attend a little to the dictate of untutored Nature, and ſee how ſhe teaches all mankind to form the ſcale of melody.

4 All nations ſing by one ſcale.

It is a moſt remarkable fact, that, in all nations, however they may differ in the ſtructure of that chaunt which we call the accent, or tone, or twang, in the colloquial language of a particular nation, or in the favourite phraſes or paſſages which are moſt frequent in their ſongs, all men make uſe of the ſame riſes and falls, or inflections of voice, in their muſical language or airs. We have heard the ſongs of the Iroquois, the Cherokee, and the Eſquimaux, of the Carib, and the inhabitant of Paraguay; of the African of Negroland and of the Cape, and of the Hindoo, the Malay, and the native of Otaheite—and we found none that made uſe of a different ſcale from our own, although ſeveral ſeemed to be very ſorry performers by any ſcale. There muſt be ſome natural foundation for this uniformity. We may never diſcover this; but we may be fortunate enough to diſcover facts in the phenomena of ſound which invariably accompany certain modifications of muſical ſentiment. If we ſucceed, we are intitled to ſuppoſe that ſuch inſeparable companions are naturally connected; and to conclude, that if we can inſure the appearance of thoſe facts in ſound, we ſhall alſo give occaſion to thoſe muſical ſentiments or impreſſions.

5 Muſical pitch, what?

There is a quality in lengthened or continued ſound which we call its pitch or note, by which it may be accounted ſhrill or hoarſe. It may be very hoarſe in the beginning, and during its continuance it may grow more and more ſhrill by imperceptible gradations. In this caſe we are ſenſible of a kind of progreſs from the one ſtate of ſound to the other. Thus, while we gently draw the bow acroſs the ſtring of a baſs viol, if we at the ſame time ſlide the finger ſlowly along the ſtring, from the nut towards the bridge, the ſound, from being hoarſe, becomes gradually acute or ſhrill. Hoarſe and ſhrill therefore are not different qualities, although they have different names, but are different ſtates or degrees of the ſame quality, like cold and heat, near and far,

early

Temperament of the Scale of Music.

early and late, or, what is common to all theſe, little and great. A certain ſtate of the air is accounted neither hot nor cold. All ſtates on one ſide of this are called warm, or hot; and all on the other are cold. In like manner, a certain ſound is the boundary between thoſe that are called hoarſe and thoſe called ſhrill. The chemiſt is accuſtomed to ſay, that the temperature of a body is higher when it is warmer, and lower when colder. In like manner, we are accuſtomed to ſay, that a perſon raiſes or depreſſes the pitch of his voice when it becomes more ſhrill or more hoarſe. The ancient Greeks, however, called the ſhriller ſounds *low*, and the hoarſer ſounds *high*; probably becauſe the hoarſer ſounds are generally ſtronger or louder, which we are alſo accuſtomed to conſider as higher. In common language, a low pitch of voice means a faint ſound, but in muſical language it means a hoarſer ſound. The ſound that is neither hoarſe nor ſhrill is ſome ordinary pitch of voice, but without any preciſe criterion.

6 The change obſerved in the pitch of a violin ſtring, when the finger is carried along the finger-board with a continued motion, is alſo continuous; that is, not by ſtarts: we call it gradual, for want of a better term, although gradual properly means *gradatim*, by degrees, ſteps, or ſtarts, which are not to be diſtinguiſhed in this experiment. But we may make the experiment in another way. After ſounding the open ſtring, and while the bow is yet moving acroſs it, we may put down the finger about $1\frac{2}{3}$ inches from the nut. This will change the ſound into one which is *ſenſibly* ſhriller than the former, and there is a manifeſt ſtart from the one to the other. Or we may put down the finger $2\frac{1}{2}$ inches from the nut; the ſound of the open ſtring will change to a ſhriller ſound, and we are ſenſible that this change or ſtep is greater than the former. Moreover, we may, while drawing the bow acroſs the ſtring, put down one finger at $1\frac{2}{3}$ inches, and, immediately after, put down another finger at $2\frac{1}{2}$ inches from the nut. We ſhall have three ſounds in ſucceſſion, each more ſhrill than the preceding, with two manifeſt ſteps, or ſubſultory changes of pitch.

7 Now ſince the laſt ſound is the ſame as if the ſecond had not been ſounded, we muſt conceive the ſum of the two ſucceſſive changes as equivalent or equal to the change from the firſt to the third. This change ſeems ſomehow to include the other two, and to be made up of them, as a whole is made up of its parts, or as $2\frac{1}{2}$ inches are made up of $1\frac{2}{3}$ and $\frac{5}{6}$ of an inch, or as the ſum 15 is made up of 10 and 5.

8 We have a notion of ſomething like an interval between the notes of muſic.

Thus it happens that thinking perſons conceive ſomething like or analogous to a diſtance, or interval, between theſe ſounds. It is plain, however, that there can be no real diſtance or ſpace interpoſed between them; and it is not eaſy to acquire a diſtinct notion of the bulk or magnitude of theſe intervals. This conception is purely figurative and analogical; but the analogy is very good, and the obſervation of it, or conjecture about it, has been of great ſervice in the ſcience of muſic, by making us ſearch for ſome preciſe meaſure of thoſe manifeſt intervals of muſical ſounds.

9 It muſt now be remarked, that it is in this reſpect alone that ſounds are ſuſceptible of muſic. Nor are all ſounds poſſeſſed of this quality. The ſmack of a whip, the exploſion of a muſket, the ruſhing of water or wind, the ſcream of ſome animals, and many other ſounds, both momentary and continuous, are mere noiſes; and can neither be called hoarſe nor ſhrill. But, on the other hand, many ſounds, which differ in a thouſand circumſtances of loudneſs, ſmoothneſs, mellowneſs, &c. which make them pleaſant or diſagreeable, have this quality of muſical pitch, and may thus be compared. The voice of a man or woman, the ſound of a pipe, a bell, a ſtring, the voice of an animal, nay, the ſingle blow on an empty caſk—may all have one pitch, or we may be ſenſible of the interval between them. We can, in all caſes, tighten or ſlacken the ſtring of a violin, till the moſt uninformed hearer can pronounce with certainty that the pitch is the ſame. We are indebted to the celebrated Galileo for the diſcovery of that phyſical circumſtance in all thoſe ſounds which communicates this remarkable quality to them, and even enables us to induce it on any noiſe whatever, and to determine, with the utmoſt preciſion, the muſical pitch of the ſound, and the interval between any two ſuch ſounds. Of this we ſhall ſpeak fully hereafter; and at preſent we only obſerve, that two ſounds, having the ſame pitch, are called UNISONS by muſicians, or are ſaid to be in *uniſon* to one another.

Temperament of the Scale of Muſic.

When two untaught men attempt to ſing the ſame air together, they always ſing in uniſon, unleſs they expreſsly mean to ſing in different pitches of voice. Nay, it is an extremely difficult thing to do otherwiſe, except in a few very peculiar caſes. Alſo, when a man and woman, wholly uninſtructed in muſic, attempt to ſing the ſame air, they alſo *mean* to ſing the ſame muſical notes through the whole air; and they generally imagine that they do ſo. But there is a manifeſt difference in the ſounds which they utter, and the woman is ſaid to ſing more SHRILL, and the man more HOARSE. A very plain experiment, however, will convince them that they are miſtaken. *N. B.* We are now ſuppoſing that the performers have ſo much of a muſical ear, and flexible voice, as to be able to ſing a common ballad, or a pſalm tune, with tolerable exactneſs, and that they can prolong or dwell upon any particular note when deſired. 10

Let them ſing the common pſalm tune called St David's, in the ſame way that they practiſe at church; and when they have done it two or three times, in order to fix their voices in tune, and to feel the general impreſſion of the tune, let the woman hold on in the firſt note of the tune, which we ſuppoſe to be *g*, while the man ſings the firſt three in ſucceſſion, namely *g*, *d*, $\overline{g}$. He will now perceive, that the laſt note ſung by himſelf is the ſame with that ſung by the woman, and which ſhe thinks that ſhe is ſtill holding on in the firſt note of the tune. Let this be repeated till the performance becomes eaſy. They will then perceive the perfect ſameneſs, in reſpect of muſical pitch, of the woman's firſt note of this tune and the man's third note. Some difference, however, will ſtill be perceived; but it will not be in the pitch, but in the ſmoothneſs, or clearneſs, or other agreeable quality of the woman's note.

11 There [are] ſeven [notes] in the natural ſ[cale] and eight notes.

When this is plainly perceived, let the man try by what continued ſteps he muſt raiſe his pitch, in order to arrive at the woman's note from his own. If he is accuſtomed to common ballad ſinging, he will have no great difficulty in doing this; and will find that, beginning with his own note, and ſinging gradually up, his eighth note will be the woman's note. In ſhort, if two flutes be taken, one of which is twice as long as the era- f the of ic.

the other, and if the man sing in unison with the large flute, the woman, while singing, as she thinks, the same notes with the man, will be found to be singing in unison with the smaller flute.

ve.

This is a remarkable and most important fact in the phenomena of music. This interval, comprehending and made up of seven smaller intervals, and requiring eight sounds to mark its steps, is therefore called an OCTAVE. Now, since the female performer follows the same dictates of natural ear in singing her tune that the man follows in singing his, and all hearers are sensible that they are singing the same tune, it necessarily follows, that the two serieses of notes are perfectly similar, though not the same: For there must be the same interval of an octave between any step of the lower octave and the same step of the upper one. In whatever way, therefore, we conceive one of these octaves to be parcelled out by the different steps, the partition of both must be similar. If we represent both by lines, these lines must be similarly divided. Each partial interval of the one must bear the same relation to the whole, or to any other interval, as its similar interval in the other octave bears to the whole of that octave, or to the other corresponding interval in it.

3 ctaves milar.

Farther, we must now observe, that although this similarity of the octaves was first observed or discovered by means of the ordinary voices of man and woman, and is a legitimate inference from the perfect satisfaction that each feels in singing what they think the same notes, this is not the only foundation or proof of the similarity. Having acquired the knowledge of that physical circumstance, on which the pitch of musical sounds depends, we can demonstrate, with all the rigour of geometry, that the several notes in the man and woman's octave *must* have the same relation to their respective commencements, and that these two great intervals are similarly divided. But farther still, we can demonstrate that this similarity is not confined to these two octaves. This may even be proved, to a certain extent, by the same original experiment. Many men can sing two octaves in succession, and there are some rare examples of persons who can sing three. This is more common in the female voice. This being the case, it is plain that there will be two octaves common to both voices; and therefore four octaves in succession, all similar to each other. The same similarity may be observed in the sounds of instruments which differ only by an octave. And thus we demonstrate that all octaves are similar to each other. This similarity does not consist merely in the similarity of its division. The sound of a note and its octave are so like each other, that if the strength or loudness be properly adjusted, and there be no difference in kind, or other circumstances of clearness, smoothness, &c. the two notes, when sounded together, are indistinguishable, and appear only like a more brilliant note. They coalesce into one sound. Nay, most clear mellow notes, such as these of a fine human voice, really contain each two notes, one of which is octave to the other.

We said that this resemblance of octaves is an important fact in the science of music. We now see why it is so. The whole scale of music is contained in one octave, and all the rest are only repetitions of this scale. And thus is the doctrine of the scale of melody brought within a very moderate compass, and the problem is reduced to that of the repartition of a single octave, and some attention to the junction with the similar scales of the adjoining octaves. This partition is now to be the subject of discussion.

Tempera-ment of the Scale of music.

15 Melodies, or tunes or airs, were the first music.

In the infancy of society and cultivation, it is probable that the melodies or tunes, which delighted the simple inhabitants were equally simple. Being the spontaneous effusions of individuals, perhaps only occasional, and never repeated, they would perish as fast as produced. The airs were probably connected with some of the rude rhimes, or gingles of words, which were bandied about at their festivals; or they were associated with dancing. In all these cases they must have been very short, consisting of a few favourite passages or musical phrases. This is the case with the common airs of all simple people to this day. They seldom extend beyond a short stanza of poetry, or a short movement of dancing. The artist who could compose and keep in mind a piece of considerable length, must have been a great rarity, and a minstrel fit for the entertainment of princes; and therefore much admired, and highly rewarded: his excellencies were almost incommunicable, and could not be preserved in any other way but by repeated performance to an attentive hearer, who must also be an artist, and must patiently listen, and try to imitate; or, in short, to get the tune by heart. It must have been a long time before any distinct notion was formed of the relation of the notes to each other. It was perhaps impossible to recollect to day the precise notes of yesterday. There was nothing in which they were fixed till instrumental music was invented. This has been found in all nations; but it appears that long continued cultivation is necessary for raising this from a very simple and imperfect state. The most refined instrument of the Greek musicians was very far below our very ordinary instruments. And, till some method of notation was invented, we can scarcely conceive how any determined partition of the octave could be made generally known.

16 KEY-NOTE or FUNDAMENTAL.

Accordingly, we find that it was not till after a long while, and by very rude and awkward steps, that the Greeks perceived that the whole of music was comprised in the octave. The first improved lyre had but four strings, and was therefore called a TETRACHORD; and the first flutes had but three holes, and four notes; and when more were added to the scale, it was done by joining two lyres and two flutes together. Even this is an instructive step in the history of musical science: For the four sounds of the instrument have a natural system, and the awkward and groping attempts to extend the music, by joining two instruments, the scale of the one following, or being a continuation of that of the other, pointed out the DIAPASON or *totality* of the octave, and the relation of the whole to a principal sound, which we now call the *fundamental* or *key*, it being the lowest note of our scale, and the one to which the other notes bear a continual reference. It would far exceed the limits of this Work to narrate the successive changes and additions made by the Greeks in their lyre; yet would this be a very sure way of learning the natural formation of our musical scale. We must refer our readers to Dr Wallis's Appendix to his edition of the Commentary of Porphyrius in Ptolemy's Harmonics, as by far the most perspicuous account that is extant of the Greek music. We shall pick out from among their differ-ent

Tempera-ment of the Scale of Muſic.

ent attempts ſuch plain obſervations as will be obvious to the feelings of any perſon who can ſing a common tune.

17
The octave is naturally divided into two TETRACHORDS.

Let ſuch a perſon firſt ſing over ſome plain and cheerful, or at leaſt not mournful, tune, ſeveral times, ſo as to retain a laſting impreſſion of the chief note of the tune, which is generally the laſt. Then let him begin, on the ſame note, to ſing in ſucceſſion the riſing ſteps of the ſcale, pronouncing the ſyllables *do, re, mi, fa, ſol, la, ſi, do*. He will perhaps obſerve, that this chaunt naturally divides itſelf into two parts or phraſes, as the muſicians term it. If he does not, of himſelf, make this remark, let him ſing it, however, in that manner, pauſing a little after the note *fa*. Thus, *do, re, mi, fa; ſol, la, ſi, do.—Do, re, mi, fa; ſol, la, ſi, do.*

Having done this ſeveral times, and then repeated it without a pauſe, he will become very ſenſible of the propriety of the pauſe, and of this natural diviſion of the octave. He will even obſerve a conſiderable ſimilarity between theſe two muſical phraſes, without being able, at firſt, to ſay in what it conſiſts.

18
The ſteps of the ſcale are unequal, and the two tetrachords are ſimilar.

Let him now ſtudy each phraſe apart, and try to compare the magnitude of the changes of ſound; or ſteps which he makes in riſing from *do* to *re*, from *re* to *mi*, and from *mi* to *fa*. We apprehend that he will have no difficulty in perceiving, after a few trials, that the ſteps *do re*, and *re mi*, are ſenſibly greater than the ſtep *mi fa*. We feel the laſt ſtep as a ſort of ſlide; as an attempt to make as little change of pitch as we can. Once this is perceived, it will never be forgotten. This will be ſtill more clearly perceived, if, inſtead of theſe ſyllables, he uſe only the vowel *a*, pronounced as in the word *hall*, and if he ſing the ſteps, ſliding or ſlurring from the one to the other. Taking this method, he cannot fail to notice the ſmallneſs of the third ſtep.

19
Let the ſinger farther conſider, whether he does not feel this phraſe muſical or agreeable, making a ſort of tune or chaunt, and ending or cloſing agreeably after this ſlide of a ſmall, or, as it were, half ſtep. It is generally thought ſo; and is therefore called a CLOSE, a CADENCE, when we end with a half ſtep aſcending.

20.
Let the ſinger now reſume the whole ſcale, ſinging the four laſt notes *ſol, la, ſi, do*, louder than the other four, and calling off his attention from the low phraſe, and fixing it on the upper one. He will now be able to perceive that this, like the other, has two conſiderable ſteps; namely, *ſol la* and *la ſi*, and then a ſmaller ſtep, *ſi do*. A few repetitions will make this clear, and he will then be ſenſible of the nature of the ſimilarity between theſe two phraſes, and the propriety of this great diviſion of the ſcale into the intervals *do, fa*, and *ſol, do*, with an interval *fa, ſol* between them.

This was the foundation of the tetrachords or lyres of four ſtrings, of the Greeks. Their earlieſt muſic or modulation ſeems to have extended no farther than this phraſe. It pleaſed them, as a ring of four bells pleaſes many country pariſhes.

21
CLOSE OR CADENCE.

The ſinger will perceive the ſame ſatisfaction with the cloſe of this ſecond phraſe as with that of the former: and if he now ſing them both, in immediate ſucceſſion, with a ſlight pauſe between, we imagine that he will think the cloſe or cadence on the upper *do* even more ſatisfactory than that on the *fa*. It ſeems to us to complete a tune. And this impreſſion will be greatly heightened, if another perſon, or an inſtrument, ſhould ſound the lower *do*, while he cloſes on the upper *do* its octave. *Do* ſeems to be expected, or looked for, or ſought after. We take *ſi* as a ſtep to *do*, and there we reſt.

Tempe ment o Scale Mu

22
The th and ſev ſtep ar ſmalleſ

Thus does the octave appear to be naturally compoſed of ſeven ſteps, of which the firſt, ſecond, fourth, fifth, and ſixth, are more conſiderable, and the third and ſeventh very ſenſibly ſmaller. Having no direct meaſures of their quantity, nor even a very diſtinct notion of what we mean by their quantity, magnitude, or bulk, we cannot pronounce with any certainty, whether the greater ſteps are equal or unequal; and we preſume them to be equal. Nor have we any diſtinct notion of the proportion between the larger and ſmaller ſteps. In a looſe way we call them half notes, or ſuppoſe the riſe from *mi* to *fa*, or from *ſi* to *do*, to be one-half of that from *do* to *re*, or from *re* to *mi*.

23
The Py gorean coveri not im prove Greek ſic.

Accordingly, this ſeems to have been all the muſical ſcience attained by the Greek artiſts, or thoſe who did not profeſs to ſpeak philoſophically on the ſubject. And even after Pythagoras publiſhed the diſcovery which he had made, or more probably had picked up among the Chaldeans or Egyptians, by which it appeared, that accurate meaſures of ſounds, in reſpect to gravity and acuteneſs, were attainable, it was affirmed by Ariſtoxenus, a ſcholar of Ariſtotle, and other eminent philoſophers, that theſe meaſures were altogether artificial, had no connection with muſic, and that the ear alone was the judge of muſical intervals. The artiſt had no other guide in tuning his inſtrument; becauſe the ratios, which were ſaid to be inherent in the ſounds (though no perſon could ſay how), were never perceived by the ear. The juſtice of this opinion is abundantly confirmed by the awkward attempt of the Greeks to improve the lyre by means of theſe boaſted ratios. Inſtead of illuſtrating the ſubject, they ſeem rather to have brought an additional obſcurity upon it, and threw it into ſuch confuſion, that although many voluminous diſſertations were written on it, and on the compoſition of their muſical ſcale, the account is ſo perplexed and confuſed, that the firſt mathematicians and artiſts of Europe acknowledge, that the whole is an impenetrable myſtery. Had the philoſophers never meddled with it, had they allowed the practical muſicians to conſtruct and tune their inſtruments in their own way, ſo as to pleaſe their ear, it is ſcarcely poſſible that they ſhould not have hit on what they wanted, without all the embarraſſment of the chromatic and enharmonic ſcales of the lyre. It is ſcarcely poſſible to contrive a more cumberſome method of extending the ſimple ſcale of Nature to every caſe that could occur in their muſical compoſitions, than what aroſe from the employment of the muſical ratios. This ſeems a bold aſſertion; but we apprehend that it will appear to be juſt as we proceed.

24
The tr poſition muſic n intercal notes ne ſary in t octave.

The practical muſicians could not be long of finding the want of ſomething more than the mere diatonic ſcale of their inſtruments. As they were always accompanied by the voice, it would often happen that a lyre or flute, perfectly tuned, was too low or too high for the voice that was to accompany it. A ſinger can pitch his tune on any ſound as a key; and if this be too high for the ſinger who is to accompany him, he can take it on a lower note. But a lyriſt cannot do this. Suppoſe his inſtrument two notes too low, and that his accompanyiſt can only ſing it on the key which

is

pera- of the e of ſic.

is the *ſi* of the lyre. Should the lyriſt begin it on that key, his very firſt ſtep is wrong, being but a half ſtep, whereas it ſhould be a whole one. In ſhort, all the ſteps but one will be found wrong, and the lyriſt and ſinger will be perpetually jarring. This is an evident conſequence of the inequality of the fourth and ſeventh ſteps to the reſt. And if the other ſteps, which we imagine to be equal, be not exactly ſo, the diſcordance will be ſtill greater.

es of tha- s and xe- about l ra-

The method of remedying this is very obvious. If the intervals *mi fa* and *ſi do*, are half notes, we need only to interpoſe other ſounds in the middle between each of the whole notes; and then, in place of ſeven unequal ſteps, we ſhall have twelve equal ones, or twelve intervals, each of them equal to a ſemitone. The lyre thus conſtructed will now ſuit any voice whatever. It will perfectly reſemble our keyed inſtruments, the harpſichord, or organ, which have twelve ſeemingly equal intervals in the octave. Accordingly, it appears that ſuch additions were practiſed by the muſicians of Greece, and approved of by Ariſtoxenus, and by all thoſe who referred every thing to the judgment of the ear. And we are confident that this method would have been adopted, if the philoſophers had had leſs influence, and if the Greeks had not borrowed their religious ceremonies along with their muſical ſcience. Both of theſe came from the ſame quarter; they came united; and it was ſacrilegious to attempt innovations. The doctrine of muſical ratios was an occupation only for the refined, the philoſophers; and by ſubjecting muſic to this myſterious ſcience, it became myſterious alſo, and ſo much the more venerable. The philoſophers ſaw, that there was in Nature a certain inſcrutable connection between mathematical ratios and thoſe intervals which the ear reliſhed and required in melody: but they were ignorant of the nature and extent of this connection.

of , di- , and aron.

What is this connection, or what is meant when we ſpeak of the ratios of ſounds? Simply this:—Pythagoras is ſaid to have found, that if two muſical cords be ſtrained by equal weights, and one of them be twice the length of the other, the ſhort one will ſound the octave to the note of the other. If it be two-thirds of the length of the long ſtring, it will ſound the fifth to it. If the long ſtring ſound *do*, the ſhort one will ſound *ſol*. If it be three-fourths of the length, it will ſound the fourth or *fa*. Thus the ratio of 2 : 1 was called the ratio of the DIAPASON; that of 3 : 2 was called the DIAPENTE; and that of 4 : 3 the DIATESSARON. Moreover, if we now take all the four ſtrings, and make that which ſounds the graveſt note, and is the longeſt, twelve inches in length; the ſhort or octave ſtring muſt be ſix inches long, or one half of twelve; the diapente muſt be eight inches, or two-thirds of twelve; and the diateſſaron muſt be nine inches, which is three fourths of twelve. If we now compare the diapente, not with the graveſt ſtring, but with the octave of ſix inches, we ſee that they are in the ratio of 4 to 3, or the ratio of diateſſaron. And if we compare the diateſſaron with the octave, we ſee that their ratio is that of 9 : 6, or of 3 : 2, or the ratio of diapente. Thus is the octave divided into a fifth and a fourth *do ſol*, and *ſol do*, in ſucceſſion. Alſo the fourth *do fa*, and the fifth *fa do*, make up the octave. The note which ſtands as a fifth to one of the extreme ſounds of the octave, ſtands as a fourth to the other. And, laſtly, the two fourths *do fa*, and *ſol do*, leave an interval *fa ſol* between them; which is alſo determined by nature, and the ratio correſponding to it is evidently that of 9 to 8.

Temperament of the Scale of Muſic.

25 The diſcovery of Pythagoras is either a fable, or falſely narrated.

This is all that was known of the connection of muſic with mathematical ratios. It is indeed ſaid by Iamblicus, that Pythagoras did not make this diſcovery by means of ſtrings, but by the ſounds made by the hammers on the anvil in a ſmith's ſhop. He obſerved the ſounds to be the key, the diateſſaron, and the diapente of muſic; and he found, that the weights of the hammers were in this proportion; and as ſoon as he went home, he tried the ſounds made by cords, when weights, in the proportions above-mentioned, were appended to them. But the whole ſtory has the air of a fable, and of ignorance. The ſounds given by a ſmith's anvil have little or no dependance on the weight of the hammers; and the weights which are in the proportions of the numbers mentioned above will by no means produce the ſounds alleged. It requires *four* times the weight to make a ſtring ſound the octave, and *twice and a quarter* will produce the diapente, and *one and ſeven-ninths* will produce the diateſſaron. It is plain, therefore that they knew not of what they were ſpeaking: yet, on this ſlight foundation, they erected a vaſt fabric of ſpeculation; and in the courſe of their reſearches, theſe ratios were found to contain all that was excellent. The attributes of the Divinity, the ſymmetry of the univerſe, and the principles of morality, were all reſolvable into the harmonic ratios.

26 Conjoined and diſjoined tetrachords.

In the attempts to explain, by means of the myſterious properties of the ratios 2 : 1, 3 : 2, 4 : 3, and 9 : 8, which were thus defined by Nature, it was obſerved, that their favourite lyres of four ſtrings could be combined in two principal manners, ſo as to produce an extenſive ſcale. One lyre may contain the notes *do, re, mi, fa;* and the acuter lyre may contain the notes *ſol, la, ſi, do;* and being ſet in ſucceſſion, having the interval *fa ſol* between the higheſt note of the one and the loweſt of the other, they make a complete octave. Theſe were called *diſjoined tetrachords.* Again, a third tetrachord may be joined with the upper tetrachord laſt mentioned, in ſuch ſort, that the loweſt note of the third tetrachord may be the ſame with the higheſt of the ſecond. Theſe were called *conjoined* tetrachords (A).

27 The lyres were tuned entirely by the ear,

By thus conſidering the ſcale as made up of tetrachords, the tuning of the lyre was reduced to great ſimplicity. The muſician had only to make himſelf perfect in the ſhort chaunt *do, re, mi, fa*, or to get it by heart, and to ſing it exactly. This intonation would apply equally to the other *ſol, la, ſi, do.* We are well informed that this was really the practice. The directions given by Ariſtoxenus, Nicanor, and others, for

 varying

(A) This is the *principle*, but not the preciſe *form*, of the diſjoined and conjunct tetrachords. The Greeks did not begin the tetrachord with what we make the firſt note of our chaunt of four notes, but began one of them with *mi*, and the other with *ſi;* to which they afterwards added a note below. This beginning ſeems to have been directed by ſome of their favourite cadences; but it would be tedious to explain it.

Temperament of the Scale of Music.

varying the tuning, according to certain occasional accommodations, shew distinctly that they did not tune as we do, sounding the two strings together, except in the case of the diapason or octave. It was all done by the judgment of the ear in melody. The most valuable circumstance in the discovery of Pythagoras was the determination of the interval between the fourth and the fifth, by which the tetrachords were separated. The filling up of each tetrachord was left entirely to the ear; and when the doctrine of the mathematical ratios shewed that the large intervals *do re*, *re mi*, *fa sol*, *sol la*, *la si*, should not be precisely equal, Aristoxenus refused the authority of the reasons alleged for this inequality, because the ear perceived none of the ratios as ratios, and could judge only of sounds. He farther asserted that the inequalities which the Pythagoreans enjoined, were so trifling, that no ear could possibly perceive them. And accordingly, the theorists disputed about the respective situations of the greater and smaller tones (so they named the great steps) so much spoken of, and had different systems on the subject.

28 And by melody alone:

But the strongest proof of the indistinct notion that the theorists entertained about the influence of these ratios in music is, that they would admit no more but those introduced by Pythagoras; and their reasons for the rejection of the ratio of 5 to 4, and of 6 to 5, were either the most whimsical fancies about the perfections of the sacred ratios, or assumptions expressly founded on the supposition, that the ear perceives and judges of the ratios as ratios; than which nothing can be more false. Had they admitted the ratio of 5 to 4, they would have obtained the third note of the scale, and would at once have gotten the whole scale of our music. The ratios of 6 : 5, and 16 : 15, follow of course; and every sound of the tetrachords would have been determined. For 5 : 4 being the ratio of the major third, which is perfectly pleasing to the ear, as the *mi* to the note *do*, and 3 : 2 being the ratio of the fifth *do sol*, there is another interval *mi sol* determined; and this ratio being the difference between *do sol* and *do mi*, or between 3 : 2 and 5 : 4, is evidently 6 : 5. In like manner, the interval *mi fa* is determined, and its ratio, being 4 : 3—5 : 4, is 16 : 15.

But farther; we shall find, upon trial, that if we put in a sound above *sol*, having the relation 5 : 4 to *fa*, it will be perfectly satisfactory to the ear if sung as the note *la*. And if, in like manner, we put in a note above *la*, having the relation 5 : 4 to *sol*, we find it satisfactory to the ear when used as *si*. If we now examine the ratios of these artificial notes, we shall find the ratio of the notes *sol la* to be 10 : 9, and that of *la si* to be 9 : 8, the same with that *fa sol*; also *si do* will appear to be 16 : 15, like that of *mi fa*.

We have no remains of the music of the Greeks, by which we can learn what were their favourite passages or musical phrases; and we cannot see what caused them to prefer the fourth to the major third. Few musicians of our times think the fourth in any degree comparable with the major third for melodiousness, and still fewer for harmoniousness. The piece or tune published by Kircher from Alypius is very suspicious, as no other person had seen the MS; and the collection found at Buda is too much disfigured, and probably of too late a date, to give us any solid help. In all probability, the common melodies of the Greeks abounded in easy leaps up and down on the third and fifth, and on the fourth and sixth, just as we observe in the airs for dancing among all simple people. Their accomplished performers had certainly great powers both of invention and execution; and the chromatic and enharmonic divisions of the scale were certainly practised by them, and not merely the speculations of mathematicians. To us, the enharmonic scale appears the most jarring discord; but this is certainly owing to our not seeing any pieces of the music so composed, and because we cannot in the least judge by harmony what the effect of enharmonic melody would be. But we have sufficient evidence, from the writings of the ancient Greeks, that the enharmonic music fell into disuse even before the time of Ptolemy, and was totally and irrecoverably lost before the 5th century. Even the chromatic was little practised, and was chiefly employed for extending the common scale to keys which were seldom used. The uncertainties respecting even the common scale remained the same as ever; and although Ptolemy gives (among others) the very same that is now admitted as the only perfect one, namely, his *diatonicum intensum*, his reasons of preference, though good, are not urged with strong marks of his confidence in them, nor do they seem to have prevailed.

These observations shew clearly, that the perception of melody alone is not sufficiently precise for enabling us to acquire exact conceptions of the scale of music. The whole of the practicable science of the ancients seems to amount to no more than this, that the octave contained five greater and two smaller intervals, which the voice employed, and the ear relished. The greater intervals seemed all of one magnitude; and the smaller intervals appeared also equal, but the ear cannot judge what proportion they bear to the larger ones. The musicians thought them larger than one-half of the great intervals (and indeed the ratio 16 : 15 of the artificial *mi fa* and *si do*, is greater than the half of 9 : 8 or 10 : 9). Therefore they allowed the theorists to call them *limmas* instead of *hemitones*, but they, as well as the theorists, differed exceedingly in the magnitudes which they assigned them. 29 But melody is quite insufficient.

The best way that we can think of for expressing the scale of the octave is, by dividing the circumference of a circle in the points C, D, E, F, G, A, and B (fig. 1.), in the proportion we think most suitable to the natural scale of melody. According to the practical notion now under our consideration, the arches CD, DE, FG, GA, and AB, are equal, containing nearly 59°; and the arches EF and BC are also equal, but smaller than the others, containing about $33\frac{1}{2}$. Now, suppose another circle, on a piece of card paper, divided in the same manner, to move round their common centre, but instead of having its points of division marked C, D, E, &c. let them be marked *do*, *re*, *mi*, *fa*, *sol*, *la*, *si*. It is plain, that to whatever point of the outer circle we set the point *do* of the inner one, the other points of the outer circle will shew the common notes which are fit for those steps of the scale. The similarity of all octaves makes this simple octave equivalent to a rectilineal scale similarly divided, and repeated as often as we please. Fig. 1. represents this instrument, and will be often referred to. A sort of symmetry may be observed in it. The point D seems to occupy the middle of the scale, and *re* seems to be the middle note of 30 Circular presentation of the scale. Plate XLIV.

npera- t of the ale of Iuſic.

of the octave. The oppoſite arch GA, and the correſponding interval *ſol la*, ſeems to be the middle interval of the octave. The other notes and intervals are ſimilarly diſpoſed on each ſide of theſe. This circumſtance ſeems to have been obſerved by the Greeks, by the inhabitants of India, by the Chineſe, and even by the Mexicans. The note *re*, and the interval *ſol la*, have gotten diſtinguiſhed ſituations in their inſtruments and ſcales of muſic.

31 toxe- i ſcale iean s and nas,

With reſpect to the diviſion of the circles, we ſhall only obſerve at preſent, that the dotted lines are conformable to the principles of Ariſtoxenus, the whole octave being portioned out into five larger and equal intervals, and two ſmaller, alſo equal. The larger are called *mean* or *medium tones*; and the ſmaller are called *limmas* or *ſemitones*. The full lines, to which the letters and names are affixed, divide the octave into the artificial portions, determined by means of the muſical ratios, the arches being made proportional to the meaſures of thoſe ratios. Thus the arches CD, FG, AB, are proportional to the meaſure or logarithm of the ratio 9 : 8; GA and DE are proportional to the logarithm of 10 : 9; and the arches EF and BC are proportional to the logarithm of 16 : 15. We have already mentioned the way in which thoſe ratios were applied, and the authority on which they were ſelected. We ſhall have occaſion to return to this again. The only farther remark that is to be made with propriety in this place is, that the diviſion on the Ariſtoxenean principles, which is expreſſed in this figure, is one of an indefinite number of the ſame kind. The only principle adopted in it is, that there ſhall be five mean tones, and two ſmall equal ſemitones; but the magnitude of theſe is arbitrary. We have choſen ſuch, that two mean tones are exactly equal to the arch CE, determined by the ratio 5 : 4. The reaſons for this preference will appear as we proceed (B).

By this little inſtrument (the invention, we believe, of a Mr D'Ormiſſon, about the beginning of laſt century), we ſee clearly the inſufficiency of the ſeven notes of the octave for performing muſic on different keys. Set the flower de luce at the Ariſtoxenean B, and we ſhall ſee that E is the only note of our lyre which will do for one of the ſteps of the octave in which we intend to ſing and accompany. We have no ſounds in the lyre for *re, mi, ſol, la, ſi*. The remedy is as clearly pointed out. Let a ſet of ſtrings be made, having the ſame relation to *ſi* which thoſe of the preſent lyre have to *do*, and inſert them in the places pointed out by the Ariſtoxenean diviſions of the moveable octave. We need only five of them, becauſe the *ſi* and *fa* of the preſent lyre will anſwer. Theſe new ſounds are marked by a +.

32 nd im- fect, and uired IPERA- NT.

But it was ſoon found, that theſe new notes gave but indifferent melody, and that either the ear could not determine the equality of the tones and ſemitones exactly enough, or that no ſuch partition of the octave would anſwer. The Pythagoreans, or partiſans of the muſical ratios, had told them this before. But they were in no better condition themſelves; for they found, that if a ſeries of ſounds, in perfect relation to the octave, be inſerted in the manner propoſed, the melody will be no better. They put the matter to a very fair trial. It is eaſy to ſee, that no ſyſtem of mean tones and limmas will give the ſame muſic on every key, unleſs the tones be increaſed, and the limmas diminiſhed, till the limma becomes juſt half a tone. Then all the intervals will be perfectly equal. The mathematicians computed the ratios which would produce this equality, and deſired the Ariſtoxeneans to pronounce on the muſic. It is ſaid, that they allowed it to be very bad in all their moſt favourite paſſages. Nothing now remained to the Ariſtoxeneans but to attempt occaſional methods of tuning. They ſaw clearly, that they were making the notes unequal which Nature made equal. The Pythagoreans, in like manner, pointed out many alterations or corrections of intervals which ſuited one tetrachord, or one part of the octave, but did not ſuit another. Both parties ſaw that they were obliged to deviate from what they thought natural and perfect: therefore they called theſe alterations of the natural or perfect ſcale a *temperament*.

Temperament of the Scale of Muſic.

The accompliſhed performers were the beſt judges of the whole matter, and they derived very little aſſiſtance from the mathematicians: For although the rigid rules delivered by them be acknowledged to be perfectly exact, the execution of thoſe rules is not ſuſceptible of the ſame exactneſs. Their lyres are tuned, not by mathematical operations, but by the ear. It does not appear that they had muſical inſtruments with divided finger-boards, like our baſs viols and guitars; and even on theſe, it is well known that the preſſure and touch of the finger may vary ſo much, that the moſt exact placing of the frets will not inſure the nice degrees of the ſounds. The flutes are the only inſtruments of the ancients that are capable of accurate ſounds. But flutemakers know very well, that they cannot be tuned by mathematical operations, but by the ear alone. This accounts for the great prices paid for a well tuned flute. Some have coſt L. 700, and L. 50 was a very common price.

Such ſeems to have been the ſtate of the ancient muſic. There was little or no ſcience in it. There was, indeed, a moſt abſtruſe and refined ſcience coupled with it; but by a very ſlight connection; and it ſeems to have been nothing more than an amuſement for the ingenious and ſpeculative Greeks. Nor could it, in our opinion, be better, ſo long as they had no guide in tuning but the judgment of the ear in melody. Many writers inſiſt that the Greeks had a knowledge of what *we* call *harmony* alſo. The word ἁρμονια is conſtantly uſed by them: but it does not mean what we call harmony, the pleaſant coaleſcence of ſimultaneous ſounds. It comes from ἁρμος, or from ἁρμοζω, and ſignifies *aptitude*, *fitneſs*, and would, in general, be better tranſlated by *ſymmetry*. But we cannot conceive that they paid any marked attention to the effect of ſimultaneous ſounds, ſo as to enjoy the pleaſure of certain conſonances, and employ them in their compoſitions. We judge in this way from the rank which they gave them in their ſcale. To prefer the fourth to the major third ſeems to us to be impoſſible, if it be meant of ſimultaneous

33 The Greeks did not cultivate the harmony of ſimultaneous ſounds.

(B) We ſhall be abundantly exact, if we make CD=61°,72; CE=115°,9; CF=149°,42; CG=210°,58; CA=265°,3; and CB=326°,48.

Temperament of the Scale of Muſic.

neous ſounds. And the reaſon which is aſſigned for the preference can have no value in the opinion of a muſician. It is becauſe the ratio of 4 : 3 is ſimpler than that of 5 : 4. For the ſame reaſon, the fifth is preferred to both, and the octave to all the three, and uniſon to every other conſonance. They would not allow the major third 5 : 4 to be a concord at all. We have made numberleſs trials of the different concords with perſons altogether ignorant of muſic. We never ſaw an inſtance of one who thought that mere uniſon gave any poſitive pleaſure. None of all whom we examined had much pleaſure from an octave. All, without exception, were delighted with a fifth, and with a major third; and many of them preferred the latter. All of them agreed in calling the pleaſure from the fifth a *ſweetneſs*, and that from the major third a *cheerfulneſs*, or *ſmartneſs*, or by names of ſimilar import. The greater part preferred even the major ſixth to the fourth, and ſome felt no pleaſure at all from the fourth. Few had much pleaſure from the minor third or minor ſixth. *N. B.* Care was taken to ſound theſe concords without any preparation—merely as ſounds—but not as making part of any muſical paſſage. This circumſtance has a great effect on the mind. When the minor third and ſixth were heard as making part of the minor mode, all were delighted with it, and called it ſweet and mournful. In like manner, the chord $\frac{6}{4}$ never failed to give pleaſure. Nothing can be a ſtronger proof of the ignorance of the ancients of the pleaſures of harmony.

34 The pleaſures of harmony ſeem to be a modern diſcovery.

We do not profeſs to know when this was diſcovered. We think it not unlikely that the Greeks and Italians got it from ſome of the northern nations whom they called *Barbarians*. We cannot otherwiſe account for its prevalence through the whole of the Ruſſian empire—the ancient Slavi had little commerce with the empire of Rome or of Conſtantinople; yet they ſung in parts in the moſt remote periods of their hiſtory of which we have any account; and to this day, the moſt uncultivated boor in the Ruſſian empire would be aſhamed to ſing in uniſon. He liſtens a little while to a new tune, holding his chin to his breaſt; and as ſoon as he has got a notion of it, he burſts out in concert, throwing in the harmonic notes by a certain rule which he feels, but cannot explain. His harmonics are generally alternate major and minor thirds, and he ſeldom miſſes the proper cadences on the fifth and key. Perhaps the invention of the organ produced the diſcovery. We know that this was as early as the ſecond century (c). It was hardly poſſible to make much uſe of that inſtrument without perceiving the pleaſure of concordant ſounds.

35 Harmony made a great change in the ſcience of muſic.

The diſcovery of the pleaſures of harmony occaſioned a total change in the ſcience of muſic. During the dark ages of Europe, it was cultivated chiefly by the monks: the organ was ſoon introduced into the churches, and the choral ſervice was their chief and almoſt their only occupation. The very conſtruction of this inſtrument muſt have contributed to the improvement of muſic, and inſtructed men in the nature of the ſcale. The pipes are all tuned by their lengths; and theſe lengths are in the ratios of the ſtrings which give the ſame notes, when all are equally ſtretched. This muſt have revived the ſtudy of the muſical ratios. The tuning of the organ was performed by conſonance, and no longer depended on the nice judgment of ſounds in ſucceſſion. The dulleſt ear, even with total ignorance of muſic, can judge, without the ſmalleſt error, of an exact octave, fifth, third, or other concord; and a very mean muſician could now tune an organ more accurately than Timotheus could tune his lyre. Other keyed inſtruments, reſembling our harpſichord, were invented, and inſtruments with fretted finger-boards. Theſe ſoon ſupplanted the lyres and harps, being much more compendious, and allowing a much greater variety and rapidity of modulation. All theſe inſtruments were the fruits of harmony, in the modern ſenſe of that word. The deficiencies of the old diatonic ſcale were now more apparent, and the neceſſity of a number of intercalary notes. The finger-board of an organ or harpſichord, running through a ſeries of octaves, and admitting much more than the accompanyment of one note, pointed out new ſources of muſical pleaſure ariſing from the fulneſs of the harmony; and, above all, the practice of choral ſinging ſuggeſted the poſſibility of a pleaſure altogether new. While a certain number of the choir performed the Cantus or Air of the muſic, it was irkſome to the others to utter mere ſounds, ſupporting or compoſing the harmony of the Cantus, without any melody or air in their own parts. It was thought probable that the harmonic notes might be ſo portioned out among the reſt of the choir, that the ſucceſſion of ſounds uttered by each individual might alſo conſtitute a melody not unpleaſant, and perhaps highly grateful. On trial, it was found very practicable. Canons, motets, fugues, and other harmonies, were compoſed, where the airs performed by the different parts were not inferior in beauty to the principal. The notes which could not be thrown into this agreeable ſucceſſion, were left to the organiſt, and by him thrown into the baſs.

By all theſe practices, the imperfections of the ſcale of fixed ſounds became every day more ſenſible, eſpecially in full harmony. Scientific muſic, or the properties of the ratios, now recovered the high eſtimation in which they were held by the ancient theoriſts; and as the muſicians were now very frequently men of letters, chiefly monks, of ſober characters and decent manners, muſic again became a reſpectable ſtudy. The organiſt was generally a man of ſcience, as well as a performer. At the firſt revival of learning in Europe, we find muſic ſtudied and honoured with degrees in the univerſities, and very ſoon we have learned and excellent diſſertations on the principles of the ſcience. The inventions of Guido, and the diſſertations of Salinas, Zarlino, and Xoni, are among the moſt valuable publications that are extant on muſic. The improvements introduced by Guido are founded on a very refined examination 36.

(c) It is ſaid that the Chineſe had an inſtrument of this kind long before the Europeans. Cauſeus ſays, that it was brought from China by a native, and was ſo ſmall as to be carried in the hand. It is certain that the Emperor Conſtantine Copronymus ſent one to Pepin king of France in 757, and that his ſon, Charlemagne got another from the Emperor Michael Paleologus. But they appear to have been known in the Engliſh churches before that time.

examination of the scale; and the temperaments proposed by the other two have scarcely been improved by any labours of modern date. Both these authors had studied the Greek writers with great care, and their improvements proceed on a complete knowledge of the doctrines of Pythagoras and Ptolemy.

37

At last the celebrated Galileo Galilei put the finishing hand to the doctrines of those ancient philosophers, by the discovery of the connection which subsists in nature between the ratios of numbers and the musical intervals of sounds. He discovered, that these numbers express the frequency of the recurring pulses or undulations of air which excite in us the sensation of sound. He demonstrated that if two strings, of the same matter and thickness, be stretched by equal weights, and be twanged or pinched so as to vibrate, the times of their vibrations will be as their lengths, and the frequency or number of oscillations made in a given time will be inversely as their lengths. The frequency of the sonorous undulations of the air is therefore inversely as the length of the string. When therefore we say that 2 : 1 is the ratio of the octave, we mean, that the undulations which produce the upper sound of this interval are twice as frequent as those which produce its fundamental sound. And the ratio 3 : 2 of the diapente or fifth, indicates, that in the same time that the ear receives three undulations from the upper sound, it receives only two from the lower. Here we have a natural connection, not peculiar to the sounds produced by strings; for we are now able to demonstrate, that the sounds produced by bells are regulated by the same law. Nay, the improvements which have been made in the science of motion since the days of Galileo, shew us that the undulations of the air in pipes, where the air is the *only* substance moved, is regulated by the same law. It seems to be the general property of sounds which renders them susceptible of musical pitch, of acuteness, or gravity; and that a certain frequency of the sonorous undulations gives a determined and unalterable musical note. The writer of this article has verified this by many experiments. He finds, that *any noise whatever*, if repeated 240 times in a second, at equal intervals, produces the note C *sol fa ut* of the Gindonian gamut. If it be repeated 360 times, it produces the G *sol re ut*, &c. It was imagined, that only certain regular agitations of the air, such as are produced by the tremor or vibration of elastic bodies, are fitted for exciting in us the sensation of a musical note. But he found, by the most distinct experiments, that any noise whatever will have the same effect, if repeated with due frequency, not less than 30 or 40 times in a second. Nothing surely can have less pretension to the name of a musical sound than the solitary snap which a quill makes when drawn from one tooth of a comb to another: but when the quill is held to the teeth of a wheel, whirling at such a rate, that 720 teeth pass under it in a second, the sound of *g in alt.* is heard most distinctly; and if the rate of the wheel's motion be varied in any proportion, the noise made by the quill is mixed in the most distinct manner with the musical note corresponding to the frequency of the snaps. The *kind* of the original noise determines the kind of the continuous sound produced by it, making it harsh and fretful, or smooth and mellow, according as the original noise is abrupt or gradual: but even the most abrupt noise produces a tolerably smooth sound when sufficiently frequent. Nothing can be more abrupt than the snap just now mentioned; yet the *g* produced by it has the smoothness of a bird's chirrup. An experiment was made, which was less promising of a sound than any that can be thought of. A stop cock was so constructed, that it opened and shut the passage through a pipe 720 times in a second. This apparatus was fitted to the pipe of a conduit leading from the bellows to the wind chest of an organ. The air was simply allowed to pass gently along this pipe by the opening of the cock. When this was repeated 720 times in a second, the sound *g in alt.* was most smoothly uttered, equal in sweetness to a clear female voice. When the frequency was reduced to 360, the sound was that of a clear but rather harsh man's voice. The cock was now altered in such a manner, that it never shut the hole entirely, but left about one-third of it open. When this was repeated 720 times in a second, the sound was uncommonly smooth and sweet. When reduced to 360, the sound was more mellow than any man's voice at the same pitch. Various changes were made in the form of the cock, with the intention of rendering the primitive noise more analogous to that produced by a vibrating string. Sounds were produced which were pleasant in the extreme. The intelligent reader will see here an opening made to great additions to practical music, and the means of producing musical sounds, of which we have at present scarcely any conception; and this manner of producing them is attended with the peculiar advantage, that an instrument so constructed can never go out of tune in the smallest degree. But of this enough at present.

38 This frequency is expressed by the musical ratios of Pythagoras.

This discovery of Galileo's completed the Pythagorean theories, by supplying the only thing wanted for procuring confidence in them. We now see that the music of sounds depends on principles as certain and as plain as the elements of Euclid, and that every thing relating to the scale of music is attainable by mathematics. It is very true that we do not perceive the ratio 3 : 2 in the diapente, as having any relation to the numbers 3 and 2. But we perceive the sweetness of sound which characterises this concord. This is undoubtedly the perception of a certain physical fact involving this ratio, as much as the sweetness on our tongue is the perception of a certain manner of acting of the particles of sugar during their dissolution in the saliva.

Concord, discord, are properties of particular ratios of frequency.

The pleasure arising from certain consonances, such as *do sol*, is not more distinctly perceived than is the disagreeable feeling which other consonances produce, such as *do re*; and it was a fair field of disquisition to discover why the one pleased and the other displeased. We cannot say that this question has been completely decided. It has been ascribed to the coincidence of vibrations. In the octave, every second vibration of the treble note may be made to coincide with every vibration of the bass. But the pleasure arising from the different consonances does by no means follow the proportions of those coincidences of vibrations; for when two notes are infinitely near to the state which would produce a complete coincidence, the actual coincidence is then exceedingly rare; and yet we know that such sounds yield very fine harmony. In tuning any concord, when the two notes are very discordant, the coinciding vibrations recur very frequently; and as we approach

Temperament of the Scale of Music.

proach nearer and nearer to perfect concord, theſe coincidences become rarer and rarer; and if it be infinitely near to perfect concord, the coincidences of vibration will be infinitely diſtant from each other. This, and many other irrefragable arguments, demonſtrate that coaleſcence of ſound, which makes the pleaſing harmony of a fifth, for example, does not ariſe from the coincidence of vibration; and the only thing which we can demonſtrate to obtain in all the caſes where we enjoy this pleaſure, is a certain arrangement of the component pulſes, and a certain law of ſucceſſion of the diſlocations or intervals between the non-coinciding pulſes. We are perfectly able to demonſtrate that when, by continually ſcrewing up one of the notes of a conſonance, we render the real coincidence of pulſes leſs frequent; the diſlocations, or deviations from perfect coincidence, approach nearer and nearer to a certain definable law of ſucceſſion; and that this law obtains completely, when the perfect ratio of the duration of the pulſe is attained, although perhaps at that time not one pulſe of the one ſound coincides with a pulſe of the other. Suppoſe two organ pipes, ſounding the note C *ſol fa ut*, at the diſtance of ten feet from each other, and that their pulſes begin and end at the ſame inſtants, making the moſt perfect coincidence of pulſes—there is no doubt but that there will be the moſt perfect harmony; and we learn by experience that this harmony is perfectly the ſame, from whatever part of the room we hear it. This is an unqueſtionable fact. A perſon ſituated exactly in the middle between them will receive coincident pulſes. But let him approach one foot nearer to one of the pipes, it is now demonſtrable that the pulſes, at their arrival at his ear, will be the moſt diſtant from coincidence that is poſſible; for every pulſe of one pipe will biſect the pulſe from the other; but the law of ſucceſſion of the deviations from coincidence will then obtain in the moſt perfect manner. A muſical ſound is the ſenſation of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious ſound is the ſenſation produced by another definite form of the agitation. This is the compoſition of two other agitations; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the ſenſation, making it pleaſant or unpleaſant.

39 Hence ariſes the great uſe of mathematics in muſic.

Our knowledge of mechanics enables us to deſcribe this form, and every circumſtance in which one agitation can differ from another, and to diſcover general features or circumſtances of reſemblance, which, in fact, accompany all perceptions of harmony. We are ſurely intitled to ſay that theſe circumſtances are ſure teſts of harmony; and that when we have enſured their preſence, we have enſured the hearing of harmony in the adjuſted ſounds. We can even go farther in ſome caſes: We can explain ſome appearances which accompany imperfect harmony, and perceive the connection between certain diſtinct reſults of imperfect coincidences, and the magnitude of the deviations from perfect harmony which are then heard. Thus, we can make uſe of theſe phenomena, in order to aſcertain and meaſure thoſe deviations; and if any rules of temperament ſhould require a certain determinate deviation from perfect harmony in the tuning of an inſtrument, we can ſecure the appearance of that phenomenon which correſponds to the deviation, and thus can produce the preciſe temperament ſuggeſted by our rules. We can, for example, deſtroy the perfect harmony of the fifth C*g*, and flatten the note *g* till it deviates from a perfect fifth in the exact ratio of 320 to 321, which the muſicians call the one-fourth of a comma. The moſt exquiſite ear for melody is almoſt inſenſible of a deviation four times greater than this; and yet a perſon who has no muſical ear at all, can execute this temperament by the rules of harmony without the error of the fortieth part of a comma.

40 BEATIN of imper fect con nances.

For this moſt valuable piece of knowledge we are indebted to the late Dr Robert Smith of Cambridge, a very eminent geometer and philoſopher, and a good judge of muſic, and very pleaſing performer on the organ and harpſichord. This gentleman, in his diſſertation on the Principles of Harmonics, publiſhed for the firſt time in 1749, has paid particular attention to a phenomenon in coexiſtent ſounds, called a *beating*. This is an alternate enforcement and diminution of the ſtrength of ſound, ſomething like what is called a cloſe ſhake, but differing from it in having no variation in the pitch of the ſounds. It is a ſort of undulation of the ſound, in which it becomes alternately louder and fainter. It may be often perceived in the ſound of bells and muſical glaſſes, and alſo in the ſounds of particular ſtrings. It is produced in this way: Suppoſe two uniſons quite perfect; the vibrations of each are either perfectly coincident, or each pulſe of one ſound is interpoſed in the ſame ſituation between each pulſe of the other. In either caſe they ſucceed each other with ſuch rapidity, that we cannot perceive them, and the whole appears an uniform ſound. But ſuppoſe that one of the ſounds has 240 pulſes in a ſecond, which is the undulation that is produced in a pipe of 24 inches long; ſuppoſe that the other pipe is only 23 inches and $\frac{7}{10}$ths long. It will give 243 pulſes in a ſecond. Therefore the 1ſt the 80th, the 160th, and the 240th pulſe of the firſt pipe will coincide with the 1ſt, the 81ſt, the 162d, and the 243d pulſe of the other. In the inſtants of coincidence, the agitation produced by one pulſe is increaſed by that produced by the other. The commencement of the next two pulſes is ſeparated a little, and that of the next is ſeparated ſtill more, and ſo on continually: the *diſlocations* of the pulſes, or their deviations from perfect coincidence, continually increaſing, till we come to the 40th pulſe of the one pipe, which will commence in the middle of the 41ſt pulſe of the other pipe; and the pulſes will now biſect each other, ſo that the agitations of the one will counteract or weaken thoſe of the other. Thus the compounded ſound will be ſtronger at the coincidences of the pulſes, and fainter when they biſect each other. This reinforcement of ſound will therefore recur thrice in every ſecond. The frequency of the pulſes are in the ratio of a comma, or 81 : 80. Therefore this conſtitutes an *uniſon imperfect by a comma*. If therefore any circumſtance ſhould require that theſe two pulſes ſhould form an uniſon imperfect by a comma, we have only to alter one of the pipes, till the two, when ſounded together, beat thrice in a ſecond. Nothing can be plainer than this. Now let us ſuppoſe a third pipe tuned an exact fifth to the firſt of theſe two. There will be no beating obſervable; becauſe the recurrence of coincident pulſes is ſo rapid as to appear a continued ſound. They recur at every ſecond vibration of the baſs, or 120 times in a ſecond.

But

Tempera- of the Scale of Music. But now, inſtead of ſounding the third pipe along with the firſt, let it ſound along with the ſecond. Dr Smith demonſtrates, that they will beat in the ſame manner as the uniſons did, but thrice as often, or nine times in a ſecond. When therefore the fifth C*g* beats nine times in a ſecond, we know that it is too ſharp or too flat (very nearly) by a comma.

41 Smith's ... to science ... practice of music ... with effect ... thereof. Dr Smith ſhews, in like manner, what number of beats are made in any given time by any concord, imperfect or tempered, in any aſſigned degree. We humbly think that the moſt inattentive perſon muſt be ſenſible of the very great value of this diſcovery. We are obliged to call it *his* diſcovery. Merſennus, indeed, had taken particular notice of this undulation of imperfect conſonances, and had offered conjectures as to their cauſe; conjectures not unworthy of his great ingenuity. Mr Sauveur alſo takes a ſtill more particular notice of this phenomenon*, and makes a moſt ingenious uſe of it for the ſolution of a very important muſical problem; namely, to determine the preciſe number of pulſes which produce any given note of the gamut. His method is indeed operoſe and delicate, even as ſimplified and improved by Dr Smith. The following may be ſubſtituted for it, founded on the mechaniſm of ſounding cords. Let a violin, guitar, or any ſuch inſtrument be fixed up againſt a wall, with the fingerboard downward, and in ſuch a manner, that a violin ſtring, ſtrained by a weight, may preſs on the bridge, but hang free of the lower end of the finger-board. Let another ſtring be ſtrained by one of the turning pins till it be in uniſon with ſome note (ſuppoſe C) of the harpſichord. Then hang weights on the other ſtring, till, upon drawing the bow acroſs both ſtrings, at a ſmall diſtance below the bridge, they are perfect uniſons, without the ſmalleſt beating or undulation, and taking care that the preſſure of the bow on that ſtring which is tuned by the pin be ſo moderate as not to affect its tenſion ſenſibly. Note exactly the weight that is now appended to it. Now increaſe this weight in the proportion of the ſquare of 80 to the ſquare of 81; that is, add to it its 40th part very nearly. Now draw the bow again acroſs the ſtrings with the ſame caution as before. The ſounds will now beat remarkably; for the vibrations of the loaded ſtring are now accelerated in the proportion of 80 to 81. Count the number of undulations made in ſome ſmall number (ſuppoſe 10) of ſeconds. This will give the number of beats in a ſecond; 80 times this number are the ſingle pulſes of the loweſt ſound; and 81 times the ſame number gives the pulſes of the higheſt of theſe imperfect uniſons.

* Mem. Acad. Par. 1702, and ...

C = 240. If this experiment be tried for the C in the middle of our harpſichords, it will be found to contain 240 pulſes very nearly; for the ſtrings will beat thrice in a ſecond. The beats are beſt counted by means of a little ball hung to a thread, and made to keep time with the beats.

Easy and exact measures of temperament. Here, then, is a phenomenon of the moſt eaſy obſervation, and requiring no ſkill in muſic, by which the pitch of any ſound, and the imperfection of any concord, may be diſcovered with the utmoſt preciſion; and by this method may concordant ſounds be produced, which are abſolutely perfect in their harmony, or having any degree of imperfection or temperament that we pleaſe. An inſtrument may generally be tuned to perfect harmony, in ſome of its notes, without any difficulty, as we ſee done by every blind Crouder. But if a certain determinate degree of imperfection, different perhaps in the different concords, be neceſſary for the proper performance of muſical compoſitions on inſtruments of fixed ſounds, ſuch as thoſe of the organ or harpſichord kind, we do not ſee how it can be diſputed, that Dr Smith's theory of the beating of imperfect conſonances is one of the moſt important diſcoveries, both for the practice and the ſcience of muſic, that have been offered to the public. We are inclined to conſider it as the moſt important that has been made ſince the days of Galileo. The only rivals are Dr Brook Taylor's mechanical demonſtration of the vibrations of an elaſtic cord, and its companion, and of the undulations of the air in an organ pipe, and the beautiful inveſtigations of Daniel Bernoulli of the harmonic ſounds which frequently accompany the fundamental note. The muſical theory of Rameau we conſider as a mere whim, not founded in any natural law; and the theory of the grave harmonics by Tartini or Romieu is included in Dr Smith's theory of the beating of imperfect conſonances. This theory enables us to execute any harmonic ſyſtem of temperament with preciſion, and certainty, and eaſe, and to decide on its merit when done.

We are therefore ſurpriſed to ſee this work of Dr Smith greatly undervalued, by a moſt ingenious gentleman in the Philoſophical Tranſactions for 1800, and called a large and obſcure volume, which leaves the matter juſt as it was, and its reſults uſeleſs and impracticable. We are ſorry to ſee this; becauſe we have great expectations from the future labours of this gentleman in the field of harmonics, and his late work is rich in refined and valuable matter. We preſume humbly to recommend to him attention to his own admonitions to a very young and ingenious gentleman, who, he thinks, proceeded too far in animadverting on the writings of Newton, Barrow, and other eminent mathematicians. We alſo beg his leave to obſerve, that Dr Smith's application of his theory may be very erroneous (we do not ſay that it is perfect), in conſequence of his notion of the proportional effects produced on the general harmony by equal temperaments of the different concords. But the theory is untouched by this improper uſe, and ſtands as firmly as any propoſition in Euclid's Elements. We are bound to add to theſe remarks, that we have oftener than once heard muſic performed on the harpſichord deſcribed in the ſecond edition of Dr Smith's Harmonics, both before it was ſent home by the maker (the firſt in his profeſſion), and afterwards by the author himſelf, who was a very pleaſing performer, and we thought its harmony the fineſt we ever heard. Mr Watt, the celebrated engineer, and not leſs eminent philoſopher, built a handſome organ for a public ſociety, and, without the leaſt ear or reliſh for muſic, tuned three octaves of the open diapaſon by one of Dr Smith's tables of beats, with the help of a variable pendulum. Signior Doria, leader of the Edinburgh concert, tried it in preſence of the writer of this article, and ſaid, "Belliſſima—ſopra modo belliſſima!" Signiora Doria attempted to ſing along with it, but would not continue, declaring it impoſſible, becauſe the organ was ill tuned. The truth was, that, on the major key of E♭, the tuning was exceedingly different from what ſhe was accuſtomed to, and ſhe would not try another key. We mention this particular, to ſhew how accurately Mr

Mr Watt had been able to execute the temperament he intended.

43 And accurate methods of temperament.

This theory is valuable, therefore, by giving us the management of a phenomenon intimately connected with harmony, and affording us preciſe and practicable meaſures of all deviations from it. It bids fair, for this reaſon, to give us a method of executing any ſyſtem of temperament which we may find reaſon to prefer. But we have another ground of eſtimation of this theory. By its aſſiſtance, we are able to aſcertain with certainty and preciſion the true untempered ſcale of muſic, which eluded all the attempts of the ingenious Greeks; and we determine it in a way ſuited to the favourite muſic of modern times, of which almoſt all the excellencies and pleaſures are derived from harmony. We do not ſay that this *total* innovation in the principle of muſical pleaſure is unexceptionable; we rather think it very defective, believing that the thrilling pleaſures of muſic depend more upon the melody or air. We appeal even to inſtructed muſicians, whether the heart and affections are not more affected *(and with much more diſtinct variety of emotion)* by a fine melody, ſupported, but not obſerved, by harmonies judiciouſly choſen? It appears to us that the effect of harmony, always filled up, is more uniformly the ſame, and leſs touching to the ſoul, than ſome ſimple air ſung or played by a performer of ſenſibility and powers of utterance. We do not wonder, then, that the ingenious Greeks deduced all their rules from this department of muſic, nor at their being ſo ſatisfied with the pleaſures which it yielded, that they were not ſolicitous of the additional ſupport of harmony. We ſee that melody has ſuffered by the change in every country. There is no Scotchman, Iriſhman, Pole, or Ruſſian, who does not lament that the ſkill in compoſing heart-touching airs is degenerated in his reſpective nation; and all admire the productions of their muſe of "the days that are paſt." They are "pleaſant and mournful to the ſoul."

But we ſtill prefer the harmonical method of forming the ſcale, on account of its preciſion and facility: and we prefer the theory of beats, *becauſe it alſo gives us the moſt ſatiſfactory ſcale of melody*; and this, not by repeated corrections and recorrections, but by a direct proceſs. By a table of beats, every note may be fixed at once, and we have no occaſion to return to it and try new combinations; for the beatings of the different concords to one baſs being once determined, every beating of any one note with any other is alſo fixed.

44 Fundamental experiment.

We therefore requeſt the reader's patient attention to the experiment which we have now to propoſe. This experiment is beſt made with two organ pipes equally voiced, and pitched to the note C in the middle of our harpſichords. Let one of them at leaſt be a ſtopped pipe, its piſton being made extremely accurate, and at the ſame time eaſily moved along the pipe. Let the ſhank of it be divided into 240 equal parts. The advantage of this form of the experiment is, that the ſounds can be continued, with perfect uniformity, for any length of time, if the bellows be properly conſtructed. In default of this apparatus, the experiment may be made with two harpſichord wires in perfect uniſon, and touched by a wheel rubbed with roſin inſtead of a bow, in the way the ſounds of the vielle or hurdygurdy are produced. This contrivance alſo will continue the ſounds uniformly at pleaſure. A ſcale of 240 parts muſt be adapted to one ſtring, and numbered from that end of the ſtring where the wheel or bow is applied to it. Great care muſt be taken that the ſhifting of the moveable bridge do not alter the ſtrain on the wire. We may even do pretty well with a bow in place of the wheel; but the ſound cannot be long held on in any pitch. In deſcribing the phenomena, we ſhall rather abide by the ſtring, becauſe the numbers of the ſcale, or length of the ſounding part of the wire, correſpond, in fact, much more exactly with the ſounds. The deviations of the ſcale of the pipe do not in the leaſt affect the concluſions we mean to draw, but would require to be mentioned in every inſtance, which would greatly complicate the proceſs.

Having brought the two open ſtrings into perfect uniſon, ſo that no beating whatever is obſerved in the conſonance, ſlide the moveable bridge ſlowly along the ſtring while the wheel is turning, beginning the motion from the end moſt remote from the bow. All the notes of the octave, and all kinds of concords and diſcords, will be heard; each of the concords being preceded and followed by a ruffling beating, and that ſucceeded by a grating diſcord. After this general view of the whole, let the particular harmonious ſtations of the bridge be more carefully examined as follows.

45 Determination of octave charac[ter] of con[cords]

I. Shift the moveable bridge to the diviſion 120. If it has been exactly placed, we ſhall hear a perfect octave without any beating. It is, however, ſeldom ſo exactly ſet, and we generally hear ſome beating. By gently ſhifting the bridge to either ſide, this beating becomes more or leſs rapid; and when we have found in which direction the bridge muſt be moved, we can then ſlide it along till the beating ceaſe entirely, and the ſounds coaleſce into one ſound. We can ſcarcely hear the treble or octave note as diſtinguiſhable from the baſs or fundamental afforded by the other ſtring. If the notes are duly proportioned in loudneſs, we cannot hear the two as diſtinct ſounds, but a note ſeemingly the ſame with the fundamental, only more brilliant. (*N. B.* It would be a great improvement of the apparatus to have a micrometer ſcrew for producing thoſe ſmall motions of the bridge.)

Having thus produced a fine octave, we can now perceive that, as we continue to ſhift the bridge from its proper place, in either direction, the beating becomes more and more rapid, changes to a violent rattling flutter, and then degenerates into a moſt diſagreeable jar. This phenomenon is obſerved in the deviation of every concord whatever from perfect harmony, and muſt be carefully kept in remembrance.

4[6] Harm[ony] more [ſenſible] than m[elo]dy.

Before we quit this concord, the octave, produced by the biſection of the pipe or ſtring, we muſt obſerve, that, with reſpect to ourſelves, the octave $c\bar{c}$ muſt beat almoſt twice in a ſecond, before we can obſerve clearly any mis-tune in it, by ſounding the notes in ſucceſſion, or as ſteps in the ſcale of melody. We never knew any ear ſo nice as to diſcover a mis-tuning when it beats but once in three ſeconds. We think ourſelves intitled therefore to ſay, that we are inſenſible of a temperament in melody amounting to one-third of a comma; and we never knew a perſon ſenſible of a temperament half this bulk.

When the imperfection of the octave is clearly ſenſible by ſounding the notes in ſucceſſion, it is extremely diſagreeable, feeling like a ſtruggle or endeavour to attain pera- of the of ſic.

tain a certain note, and a failure in the attempt. This ſeems owing to the familiar ſimilarity of octaves, in the habitual talking and ſinging of men and women together. But when the notes are ſounded together, although we are not much more ſenſible of the imperfection of the harmony directly, as a failure in the ſweetneſs of the concord, we are very ſenſible of this phenomenon of beating; and any perſon who can diſtinguiſh a weak ſound from a ſtronger one, can eaſily perceive, in this indirect manner, any fraction of a comma, however minute. This makes the tuning by harmony much more exact than by melody alone. It is alſo much more accommodated to the genius of modern muſic. The ancients had favourite paſſages, which were frequently introduced into their airs, and they were ſolicitous to have theſe in good tune. It appears from paſſages in the writings of Galen, that different performers excelled chiefly in their ſkill in making thoſe occaſional temperaments which their muſic required. Our muſic is much more ſtrict, by reaſon of our harmonic accompaniments, which are an abominable noiſe when mis-tuned in a degree, which would have paſſed with the ancients for very good melody. Ariſtoxenus ſays, that the ear cannot diſcover the error of a comma. This would now be intolerable.

7 es the cale elody. But another advantage attends our method. We obtain by its aſſiſtance, the moſt perfect ſcale of melody; perfect in a degree attainable only by chance by the Greeks. This is now to be our buſineſs to unfold.

8 mina- f the II. Set the moveable bridge at 158, and ſound the two ſtrings. They will beat very diſagreeably, being plainly out of tune. Slide it gradually toward 160, and the beats will grow ſlower and ſlower; will change to a gentle and not unpleaſant undulation; and at laſt, when the bridge is at 160, will vaniſh entirely, and the two ſounds will coaleſce into one ſweet concord, in which neither of the component ſounds can be diſtinguiſhed. If the ſound given by the ſhort ſtring be now examined as a ſtep in the ſcale of melody, it will be found a fifth to the ſound of the long ſtring or fundamental note, perfectly ſatisfactory to the niceſt ear. Thus one ſtep of the ſcale has been aſcertained.

III. Slide the bridge ſlowly along the ſtring. The beating will recommence, and will become a flutter, and then a jarring noiſe; and will again change to an angry flutter, beating about eight times in a ſecond, when the bridge ſtands at 169 nearly. Puſhing it ſtill on, but very ſlowly, the flutter will become an indiſtinct jarring noiſe; which, by continuing the motion, will again become a flutter, or beat about ſix in the ſecond. The bridge is now about 171.

9 mina- of the IV. Still continuing the motion, the flutter becomes a jarring noiſe, which continues till the bridge is near to 180, when the rapid flutter will again be heard. This will become ſlower and ſlower as we approach to 180: and when the bridge reaches that point, all beating vaniſhes, and we have a ſoft and agreeable concord, but far inferior to the former concord in that cheering ſweetneſs which characteriſes the fifth. When this note is compared with that of the fundamental ſtring as a ſtep in the ſcale of melody, it is found to correſpond to the note *fa*, or the fourth ſtep in the ſcale, and in that employment to give complete ſatisfaction to the ear.

V. Still advancing the moveable bridge toward the nut, we ſhall hear the beatings return again; and after fluttering and degenerating to a jarring noiſe, by a very ſmall motion of the bridge, they will again be heard, will grow ſlower, accompanied with a ſort of angry expreſſion, and will ceaſe entirely when the bridge reaches the 192d diviſion of our ſcale. Here we have another concord of very peculiar character, being remarkably enlivening and gay. This ſound gives perfect ſatisfaction to the ear, if employed as the third ſtep in the ſcale of melody, being the note *mi* of that ſeries, at leaſt in all gay or cheerful airs.

Temperament of the Scale of Muſic.

50 Determination of the IIId.

VI. As we move the bridge from 192 to 200, we hear again the ſame beatings, which, in the immediate vicinity to 192, have a peeviſh fretful expreſſion, inſtead of the angry waſpiſh expreſſion before mentioned. When the bridge has paſſed that ſituation which produces only grating diſcordance, we hear the beatings again, and they become ſlower, and ceaſe altogether when the bridge arrives at 200. Here we have another conſonance, which muſt be called a *concord*, becauſe it is rather agreeable than otherwiſe, but ſtrongly marked by a mournful melancholy in the expreſſion. In the ſcale of melody, it forms the third ſtep in thoſe airs which expreſs lamentation or grief. It is called the *minor third*, to diſtinguiſh it from the laſt enlivening concord, which, being a larger interval, is called the *major third*. 51

It is well known, that theſe two thirds give the diſtinguiſhing characters to the only two modes of melodious compoſition that are admitted into modern muſic. The ſeries containing the major third is called the *major*, and that containing the minor third is called the *minor mode*. It is worthy of remark, that the fanatical preachers, in their conventicles and field ſermons, affect this mode in their harangues, which are often diſtinctly muſical, modulating entirely by muſical intervals, and keeping the whole of their chaunt in ſubordination to a fundamental or key note. This is not unnatural, when we conſider the general ſcope of their diſcourſes, namely, to inſpire melancholy and humiliating thoughts, awakening ſorrow, and the like. It is not ſo eaſy to account for the uſual whine of a beggar, who generally craves charity in the major third. This is the caſe, at leaſt, in the northern parts of this iſland. 52 Determination of the 3d.

If we continue to ſhift the bridge ſtill nearer to the end of the ſtring, we ſhall hear nothing but a ſucceſſion of vile diſcordant noiſes, ſomewhat leſs offenſive when the bridge is about the diviſions 213 and 216, but even there very unpleaſant. 53

VII. Let us therefore change our manner of proceeding a little, and again place the bridge at 160, which will give us the pleaſing concord of the fifth. Inſtead of puſhing it from that place towards the nut, let it be moved towards the wheel or bow. Without repeating what we have ſaid of the reappearance of the beatings, their acceleration, and their degenerating into a jarring diſcord, to be afterwards ſucceeded by another beating, &c. &c. we ſhall only obſerve, that when we place the bridge at 150, we have no beatings, and we hear a conſonance, which is in a ſlight degree pleaſant, and may therefore be called a *concord*. It has the other marks of a concord which we have been making ſo much uſe of; for the beatings recommence when we ſhift the bridge to either ſide of 150. This note makes the ſixth ſtep in the deſcending ſcale of mournful me- 54 Determination of the 6th.

Temperament of the Scale of Music.

lody; that is, when we are passing from the acute to the graver notes, with the intention of putting an emphasis on the third and the fundamental. Although not eminent as a concord with the fundamental alone, it has a most pleasing effect when listened to in subordination to the whole series, or when sounded along with other proper accompaniments of the fundamental.

55 Determination of the VIth.

VIII. Placing the bridge at 144, we obtain another very pleasing concord, differing in its expression from any of the foregoing. We find it difficult to express its character. It is greatly inferior to the fifth in sweetness, and to the major third in gaiety, but seems to possess, in a lower degree, both of those qualities. In the scale of cheerful melody, it is the sixth note, which we have distinguished by the syllable *la*. It is also used even in mournful melody, when we are ascending, with the intention of closing with the octave.

56 Scale of the upper octave.

In shifting the bridge from 144 to 120, we obtain nothing but discordant, or least disagreeable consonances. And, lastly, if we move the bridge beyond 120, to divisions which are respectively the halves of those numbers which produced the concords already treated of, we obtain the same steps in the scale of the upper octave. Thus if the bridge be at 80, we have the fifth to the octave note, or twelfth to the fundamental. If it be at 60, we obtain the double octave, &c. &c. &c.

57 Characters of the different concords.

We have perhaps been rash in affixing certain moral or sentimental characters to certain concords; for we have seen instances of persons who gave them different denominations; but these were never contradictory to ours, but always expressed some sentiment allied to that which we have assigned. We never met with an instance of a person capable of a little discriminating reflection, who did not acknowledge a manifest sentimental distinction among the different concords which could not be confounded. We doubt not but that the Greeks, a people of exquisite sensibility to all the beauties of taste and sentiment, paid much attention to these characters, and availed themselves of them in their compositions. We do not think it at all unlikely, that greater effects have been produced by their music, which was studied with this express view, than have ever been produced by the modern music, with all the addition of harmony. We have allowed too great a share of our attention to mere harmony. Our great authors are much less solicitous to compose an enchanting air, than to construct a full score of rich and well conducted harmony. We do not profess to be nice judges in musical composition, but we may tell what we ourselves experience. We find our minds worked up by a continuance of fine harmony into a *general* sensibility; into a frame of mind which would prepare and fit us for receiving strong impressions of moral sentiment, if these were distinctly made. But we have seldom felt any distinct emotions excited by mere instrumental music. And when the harmonics have been merely to support the performance of a voice, the words have been either so frittered by musical divisions, as to become in some measure ludicrous—or have been so indistinct, and made so trifling a part of the music, that there was nothing done to give a particular shape to the moral impression on our mind. We have generally been strongly affected by some of the anthems which were in vogue in former times; and we think that we perceived the cause of this difference: There was a great simplicity in the voice parts: the syllables were not drawled out into long musical phrases, but pronounced nearly according to their proper quantities; so that the sentiment of the speaker was expressed with all the force of good declamation, and the harmony of the accompaniment then strengthened the appropriate effect of the melody. We mean not to offer these observations as of much authority, but merely to mention some facts, and to assign what we felt to be their causes, in order to promote, in some degree, however insignificant, the cultivation of musical science. With this view, we venture to say, that some of the best compositions of Knapp of York *uniformly* affect us more than the more admired anthems of Bird and Tallis. A cadence, which Knapp gives almost entirely to the melody, is laboured by Bird or Tallis with all the rules of art; and you have its characters of perfect or imperfect, full or disappointed, cadences, and such an apparatus of preparation and resolution of discords, that you foresee it at the distance of several bars, and then the part assigned to the voice seems a very trifle, and merely to fill up a blank in the harmony. Such compositions smell of the lamp, and fail of their purpose, that of charming the *learned* ear. But enough of this digression.

Temperament of the Scale of Music.

Thus have we found a natural relation between certain sounds strongly marked by very precise characters. The concordance of sound is marked by the absence of all undulation, and the deviations from this harmony are shewn to be measurable by the frequency of those undulations. We have also found, that the notes, which are thus harmonious along with the fundamental, are steps in the scale of natural music (for we must acknowledge melody to be the primitive music, dictated by nature). We have got the notes *do—mi*, *fa*, *sol*, *la—do*, ascertained in a way that can no longer be mistaken. 58.

Let us now examine what physical or mechanical relations these sounds stand in to each other. Our monochord gives us the lengths of the strings; and the discovery of Galileo shews us, that these are also the durations of the aëreal pulses which produce the sensations of musical notes. Their ratios may therefore be truly called the ratios of the sounds. Now we see that the strings which produce the sounds *do sol* are 240 and 160. These are in the ratio of 3 to 2. In this manner we may state all the ratios observed in our experiment, *viz.*

59 Ratios belonging to the concords, &c.

Do : *mi* have the ratio of	240 to 192, or of	5 to 4
Do : *fa*	240 : 180	4 : 3
Do : *sol*	240 : 160	3 : 2
Do : *la*	240 : 144	5 : 3
Mi : *sol*	192 : 160	6 : 5, = *do* : *mi*^{b}
Fa : *sol*	180 : 160	9 : 8
Sol : *la*	160 : 144	10 : 9
Mi : *fa*	192 : 180	16 : 15

Here we get the sight of all the ratios which the ingenious and unwearied speculations of the Greek mathematicians enlisted into the service of music, without being able to give a good reason why. The ratio 5 : 4, which their fastidious metaphysicians rejected, and which others wished to introduce from motives of mere necessity to fill up a blank, is pointed out to us by one of the finest concords. The interval between the fourth and the fifth is, *very fortunately*, a step of the scale.

The next step *sol la* is more important. For the ear for pera- of the le of sic. for melody would have been very well satisfied with an interval equal to *fa sol*, or 9 : 8; but if the moveable bridge be set at the division 142$\frac{2}{9}$, corresponding to such a step, we should have a very offensive fluttering. It is reasonable therefore to conclude, *from analogy*, that the interval *sol la* does not correspond to the ratio 9 : 8; and that 10 : 9, which is, at least, equally satisfactory to the ear, is the proper step, even in the scale of melody. If we consider what may be called the scale of harmony, there is no room left for doubt. To enjoy the greatest possible pleasure of harmony, we must not only take each note as it is related to the fundamental, but also as it is related to other notes of the scale. It may chance to be convenient to assume, for the fundamental of our occasional scale of modulation, the string of the lyre which is tuned as *fa* to its proper fundamental; or it may increase the harmony (and we know that it does), if we accompany the note *do* with both of the notes *fa* and *la*. To have the fine concord of the major third, it is necessary that the interval *fa la* be equivalent to the ratio 5 : 4. Now *fa* is 180, and 5 : 4 = 180 : 144. Therefore, by making the step *sol la* equal to 9 : 8, we should lose this agreeable concord, and get discord in its place.

o va- on the sol la.

And thus is evinced, in opposition to Aristoxenus, the propriety of having both a major and a minor tone; the first expressed by 9 : 8, and the last by 10 : 9. The difference between these steps is the ratio 81 : 80, called a comma by the Greek theorists.

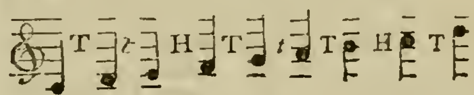
1 mina- f the We still want two steps of the scale, and two sounds or notes corresponding to them, namely *re* and *si*; and we wish to establish them on the same authority with the rest. We see that this cannot be done by a concordance with the fundamental *do*. The ear sufficiently informs us that the steps *do re* and *la si* must be tones, and not semitones, like *mi fa*. The sensible similarity of the two tetrachords *do re mi fa* and *sol la si do*, also teaches us that the step *si do* should be a semitone like *mi fa*. This seems to be all that mere melody can teach us. But we have little information whether we shall make *la si* a major or a minor tone. If we copy the tetrachord *do re mi fa* exactly, we shall make the step *si do* like *mi fa*, and equivalent to the ratio 16 : 15. This requires the moveable bridge to be placed at 128. The sound produced by this division is perfectly satisfactory to the ear as a step of the scale of melody. Moreover, our satisfaction is not confined to the comparison of it with the note *do*, into which we slide by this gentle step. It makes agreeable melody when used as the third to the note *sol*. If we examine it mathematically, we find it a perfect major third to *sol*; for *sol* requires the 160th division. Now 160 : 128 = 5 : 4, which is the ratio of the pulses of a major third. All these reasons seem enough to make us adopt this determination of the note *si*.

2 mina- f the It remains to consider how we shall divide the interval *do—mi*. It is a perfect major third. So is *fa la*, and so is *sol si*. But in the first of these two, we have seen that it must be composed of a major tone with a minor tone above it; and in the second we have a minor tone followed by a major tone above. We are left uncertain therefore whether *do re* shall resemble *fa la* or *sol si* in the position of its two parts. Aristoxenus and his followers declared the ear to be equally pleased with both. Ptolemy's *Systema Diatonicum Intensum* makes *do* *re* a major tone, and other systems make it a minor. Even in modern times it has been considered as uncertain; and the only reason which we have to offer for a preference of the major tone for the first step is, that, so far as we can judge by our own feelings, the sounds in the relation of 9 : 8 are less discordant than sounds in the relation of 10 : 9, and because all the other steps have been determined by means of concords with the key. We refer, for a more particular examination of the principles on which these arrangements are valued, to *Dr Smith's Harmonics*, Prop. I. where he shews how one is preferable to another, in proportion as it affords a greater number of perfect concords among the neighbouring notes, which is the favourite object in all modern music. Upon this principle our arrangement is by far the best, because it admits five more concords in the octave than the other. But we have considered the subject in a different manner, merely to avail ourselves of the phenomenon by which all the steps, except one, seem to be naturally ascertained, and by which the connection between harmony and melody seems to be pointed out to us.

Temperament of the Scale of Music.

It will be convenient to represent the tones major and minor and the hemitone, by the symbols T, *t*, and H. Also to mark the notes by the Roman numerals, or by cyphers, according as they are the extremes of major or minor intervals. By this notation the octave may be represented thus: 63.

C D E F G A B *c* *d* *e*



$\frac{8}{9}$ $\frac{9}{10}$ $\frac{15}{16}$ $\frac{8}{9}$ $\frac{9}{10}$ $\frac{8}{9}$ $\frac{15}{16}$ $\frac{8}{9}$ &c.

K II III 4 V VI VII VIII IX X &c.

The reader will remark, that the primary divisions which we assigned to the representation of an octave in fig. 1. by the circumference of a circle, are in conformity to this Ptolemaic partition of the octave. He will also be sensible, that the division into five equal mean tones and two equal hemitones, which is expressed by the dotted lines, agreeing with the Ptolemaic division only at C and E, is effected by bisecting the arch CE; and therefore the deviation of the sound substituted for the Ptolemaic D is half the difference of CD and DE, that is, half a comma. The deviations therefore at F, G, A, and B, are each a quarter of a comma.

Logarithmic measures of the musical intervals.

It is well known, that if the logarithm of the length of one string be subtracted from that of another, the difference is a measure of the ratio between them. Therefore 30103 is the measure of the musical interval called the octave, and then the measures of the

Comma - -	540 or	54
Hemitone -	2803	280
Minor tone - -	4576	458
Major tone -	5115	512
3d - - -	7918	792
IIId - -	9691	969
4th - - -	12494	1249
Vth - - -	17609	1761
6th - - -	20412	2041
VIth - -	22185	2219
VIIth - - -	27300	2730
VIIIth - -	30103	3010

This

Temperament of the Scale of Music.

This is a very convenient circumstance. If we take only the four first figures as integers, and make the octave consist of 3010 parts, we have a scale more exact than the nicest harmony requires. The circumference of a circle may be so divided into 301 degrees, and the moveable circle have a nonius, subdividing each into 10. Or it may be divided into 55,8 degrees, each of which will be a comma. Either of these divisions will make it a most convenient instrument for expeditiously examining all temperaments of the scale that can be proposed. Or a straight line may be so divided, and repeated thrice. Then a sliding ruler, divided in the same manner, and applied to it, will answer the same purpose. We shall see many useful employments of these instruments by and by.

64. Having thus endeavoured to communicate some plain notion of the formation and singular nature of that gradation of sounds which produces all the pleasures of music, and of the manner of obtaining the steps of this gradation with certainty and precision, we proceed to consider how those musical passages may be performed on such keyed instruments as the organs and harpsichords, as they are now constructed. These instruments have twelve sounds and intervals in every octave, in order that an air may be performed in any pitch; that is, taking any one of the sounds as a key note. It is plain that this cannot be done with accuracy; for we have now seen that the interval *mi fa* is bigger than half of *do re* or *re mi*, &c. and therefore the intercalary sound formerly mentioned to be inserted between C and D, D and E, &c. will not do indiscriminately for the sharp of the sound below and the flat of the sound above it. When the tones are reduced to a mean size, the ear is scarcely sensible of the change in melody, and the harmony of the fifths and fourths is not greatly hurt. But when the half notes are inserted, and employed to make up harmonious intervals, as recommended by Zarlino, the harmony is very coarse indeed.

65 Why temperament necessary.

But we must make the reader sensible of the necessity of some temperament, even independent of those artificial notes. Therefore

Let the scholar tune upwards the four Vths $c\,g$, $g\,\bar{d}$, $\bar{d}\,\bar{a}$, $\bar{a}\,\bar{\bar{e}}$, all perfect, admitting no beating whatever. This is easily done, either with the organ or the wheel monochord already described. Then tune downwards the perfect octaves $\bar{\bar{e}}\,\bar{e}$, $\bar{e}\,e$. Now examine the IIId $c\,e$ which results from this process. If the instrument be of the pitch hitherto supposed (c making 240 pulses in a second), this IIId will be heard beating 15 times in a second, which is a discordance altogether intolerable, the note e being too sharp in the ratio of 81 to 80, which makes a comma. It is easily found, by calculation, that e makes $303\frac{3}{4}$ pulses, instead of 300, required for the IIId to c.

N. B. It may not be amiss to inform our readers, that if any concord, whose perfect ratio is $\frac{m}{n}$ (m being the greatest term of the smallest integers expressing that ratio), be tempered sharp by the fraction $\frac{p}{q}$ of a comma, and if M and N be the pulses made by the acute and grave notes of the concord during any number of seconds, the number b of beats made in the same time by this concord will be $= \frac{2\,q\,m\,N}{161\,p - q}$, or $\frac{2\,q\,n\,M}{161\,p + q}$; and if it be tempered flat, then $b = \frac{2\,q\,m\,N}{161\,p + q}$, or $\frac{2\,q\,n\,M}{161\,p - q}$ (*Smith's Harm.* 2d edit. p. 82, &c.)

66 It is impossible, therefore, to have perfect Vths and perfect IIIds at the same time. And it will be found, that the 3d $\underline{e}\,g$ resulting from this process, and the VIth $c\,a$, are still more discordant, rattling at an intolerable rate. Now the major and minor thirds, alternately succeeding each other, form the greatest part of our harmonies; and the VIth is also a very frequent accompaniment. It is necessary therefore to sacrifice somewhat of the perfect harmony of the Vths, in order that we may not be disgusted with the discord of those other harmonies: and it is this mutual accommodation, and not the changes made necessary by the introduction of intercalary notes, which is properly called TEMPERAMENT. It will greatly assist us in understanding the effects of the temperaments of the different concords, if we examine all the divisions of the circular representation of the octave and musical scale given in fig. 1. by placing the index of the moveable circle on that note of the outer circle for which we want the proper harmonies, or accompaniments, which are either the IIId and Vth, or the 4th and VIth. We shall thus learn, in the *first* place, the deviations of the different perfect notes of the scale from the notes required for this new fundamental; and we must then study what effect the same temperament produces on the agreeableness of the harmony of different concords having the same bass or the same treble, taking it for granted that the hurt to the harmony of any individual concord is proportional to its temperament.

67 How the ... may be ... tained by the beats.

It is in this delicate department of musical science that we think the great merit of Dr Smith's work consists. We see that the deviation from perfect harmony is always accompanied with beats, and increases when they increase in frequency—whether it increases in the same proportion may be a question. We think that Dr Smith's determination of the equality of imperfect harmony in his 13th proposition includes every mathematical or physical circumstance that appears to have any concern in it. What relates immediately to our sensations is, as yet, an impenetrable secret. The theory of beats, as delivered by this author, affords very easy, though sometimes tedious, methods of measuring and of ensuring all the varieties which can obtain in the beating of imperfect consonances. It appears to us therefore very unjust to say, with the late writer in the Philosophical Transactions, that this obscure volume has left the matter where it found it. The author has give us *effective* principles, although he may have been mistaken in the application; which however we are far from affirming. Our limits will not allow us to give any account of that theory; and indeed our chief aim in the present article is to give a method of temperament which requires no scientific knowledge of the subject. But we could not think of losing the opportunity of communicating, by the way, to unlearned persons, some more distinct notions of the scale of musical sounds, and of its foundation in nature, than scholars usually receive from the greater number era- f the of fic. number of mere muſic maſters. The acknowledged connection of the muſical ratios with the pleaſures of harmony and melody, has (we hope) been employed in an eaſy and not obſcure manner; and the phenomena which we have faithfully narrated, ſhew plainly that, by diminiſhing the rattling undulations of tempered concords, we are certain of improving the harmony of our inſtruments. We ſhall proceed therefore on this principle for the uſe of the mere performer, but at the ſame time introducing ſome very ſimple deductions from Smith's theory, for which we expect the thanks of all ſuch readers as wiſh to ſee a little of the reaſons on which they are to proceed.

8 od in ce. The experiment, of which we have juſt now given an account, ſhews that four conſecutive fifths compoſe a greater interval than two octaves and a major third. Yet, in the conſtruction of our muſical inſtruments of fixed ſounds, they muſt be conſidered as of equal extent; ſince we have 7 half intervals in the Vth, and 12 in the octave, and four in the IIId, four Vths contain 28, and two octaves contain 24; and theſe, with the four which compoſe a IIId, make alſo 28. It is plain, therefore, that whatever we do with the IIIds, we muſt leſſen the Vths. If therefore we keep the IIId perfect, we muſt leſſen each of the Vths by $\frac{1}{4}$th of a comma; for we learned, by the beating of the imperfect IIId *c e*, that the whole exceſs of the four Vths was a comma. Therefore the Vth *c g* muſt be flattened $\frac{1}{4}$th of a comma. But how is this to be done with accuracy? Recollect the formula given a little ago, where the number of beats *b* in any number of ſeconds is $= \frac{2qmN}{161 \times p + q}$. In the preſent caſe $q = 1$, $m = 3$, $N = 240$ per ſecond, and $p = 4$. Therefore the formula is $= \frac{2 \times 3 \times 240}{161 \times 4 + 1} = \frac{1440}{645} = 2{,}25$ in a ſecond, or 9 beats in four ſeconds very nearly.

In like manner, the next Vth $g\,\bar{d}$ muſt be flattened $\frac{1}{4}$th of a comma, by making it beat half as faſt again, or $13\frac{1}{2}$ beats in four ſeconds (becauſe in this Vth $N = 360$). But as this beating is rather too quick to be eaſily counted, it will be better to tune downwards the perfect octave *g* G, which will reduce N to 180 for the Vth G *d*. This will give us 1,68 per ſecond, or 10 beats in 6 ſeconds very nearly.

There is another way of avoiding the employment of too quick beats. Inſtead of tuning the octave *g* G, make *c* G beat as often as *c g*. This is even more exactly an octave to *g* than can be eſtimated by a good ear. Dr Smith has demonſtrated, that when a note makes a minor concord with another note below it, and therefore a major concord with the octave to that note, it beats equally with both; but if the major concord be below, it beats twice as faſt with the octave above. Now, in the preſent caſe, *c g* is a Vth, and *c* G a 4th. For the ſame reaſon *c f* would beat twice as faſt as *c* F.

In the next place, the Vth $\bar{d}\,\bar{a}$ muſt be made to beat flat 15 times in 6 ſeconds.

In like manner, inſtead of tuning upward the Vth $\bar{a}\,\bar{\bar{e}}$, tune downward the octave $\bar{a}$ *a*, and then tune upward the Vth *a e*, and flatten it till it beat 15 times in 8 ſeconds.

If we take 15 ſeconds for the common period of all theſe beats, we ſhall have — Temperament of the Scale of Muſic.

The beats of $c\,g = 34$.
G $d = 25$.
$\bar{d}\,\bar{a} = 37\frac{1}{2}$.
$a\,e = 28$.

69. We ſhall now find *c e* to be a fine IIId, without any ſenſible beating; and then we proceed in the ſame way, always tuning upward a perfect Vth; and when this would lead us too high, and therefore produce too quick beating, we ſhould tune downward an octave. Do this till we reach *b*♯, which ſhould be the ſame with $\bar{c}$, or a perfect octave above *c*. This will be a full proof of our accurate performance. But the beſt proceſs of tuning is to ſtop when we get to *g*♯. Then we tune Vths downward from *c*, and octaves upward when the Vths would lead us too low. Thus we get *c* F, F*f*, *f b*♭, *b*♭, $\bar{b}$♭, $\bar{b}$♭ *e*♭, and thus complete the tuning of an octave. We take this method, inſtead of proceeding upwards to $\bar{b}$♯; becauſe thoſe notes marked ſharp or flat are, when tuned in this way, in the beſt relation to thoſe with which they are moſt frequently uſed as IIIds.

70 Uſe of a variable pendulum. The proceſs of temperament will be greatly expedited by employing a little pendulum, made of a ball of about two ounces weight, ſliding on a light deal rod, having at one end a pin hole through it. To prepare this rod, hang it up on a pin ſtuck into the wainſcoting, and ſlide the ball downward, till it makes 20 vibrations in 15″, by comparing it with a houſe clock. In this condition mark the rod at the upper edge of the ball. In like manner, adjuſt it for 24, 28, 32, 36, 40, 44, 48, vibrations, making marks for each, and dividing the ſpaces between them by the eye, noticing their gradual diminution. Then, having calculated the beats of the different Vths, ſet the ball at the mark ſuited to the particular concord, and temper the ſound till the beats keep pace exactly with the pendulum.

71 Abſolute number of pulſes how known. But, previous to all this, we muſt know the number of pulſes made in a ſecond by the C of our inſtrument. For this purpoſe we muſt learn the pulſes of our tuning fork. To learn this, a harpſichord wire muſt be ſtretched by a weight till it be uniſon or octave below our fork: then, by adding $\frac{1}{40}$th of the weight to what is now appended, it will be tempered by a comma, and will beat, when it is ſounded along with the fork; and we muſt multiply the beats by 80: The product is the number of pulſes required. And hence we calculate the pulſes of the C of our inſtrument when it is tuned in perfect concord with the fork.

The uſual concert pitch and the tuning forks are ſo nearly conſonant to 240 pulſes for C, that this proceſs is ſcarcely neceſſary, a quarter of a tone never occaſioning the change of an entire beat in any of our numbers.

72 Syſtem of temperament with perfect IIIds. The intelligent reader cannot but obſerve, that this ſyſtem of tuning with perfect IIIds, which is preferred to all others by many great maſters, is the one repreſented by our circular figure of the octave. The IIId is there perfect, and the Vth C G is deficient by a quarter of a comma. We cannot here omit taking notice of a moſt valuable obſervation of Dr Smith's on this temperament, and, in general, on any diviſion of the octave into mean tones and equal limmas.

The octave being made up of five mean tones and two limmas, it is plain that by enlarging the tones,

we

Temperament of the Scale of Music.

we diminish the limmas, and that the increment of the tone is two-fifths of the contemporaneous diminution of the limma If, therefore, we employ the symbol v to express any minute variation of this temperament, and make the increment of a mean tone $= 2\ v$, the contemporaneous variation which thus induces on a limma will be $= -5 v$; and if the tone be diminished by the same quantity $- 2\ v$, the limma will increase by the quantity $5\ v$. Let us see what are the contemporaneous changes made on all the intervals of the octave when the tone is diminished by $2\ v$.

73 Proportional variations of temperament.

1. A Vth is made up of three tones and a limma. Therefore the variation of its temperament is $= -6 v + 5 v$, or is $= - v$. That is, the Vth is flattened from its former temperament, whatever that may have been, by the quantity $- v$. Consequently the 4th, which is always the complement of the Vth to the octave, has its temperament sharpened by the quantity v.

2. A IId, being a tone distant from the fundamental, has its temperament changed by $- 2\ v$.

Therefore a minor 7th is raised by $2\ v$.

3. A minor 3d is made up of a tone and a limma: therefore its variation is $= - 2\ v + 5\ v$, or $= 3\ v$.

Therefore a major VIth (its complement) loses $- 3\ v$.

4. A maj. IIId, or two tones, has its variation $= -4\ v$.

Therefore a minor 6th has its variation $= 4\ v$.

5. A maj. VIIth, the complement of a limma has $-5\ v$.

6. A tritone, or IVth, must have the variation $= -6\ v$.

Therefore the false 5th must have - - $6\ v$.

74 Geometrical construction founded on this.

From this observation, Dr Smith deduces the following simple mathematical construction: In the strait line CE fig. 2. take the six equal parts C*g*, *g d*, *d a*, *a* E, E *b*, *b t*, and draw through the points of division the six parallel lines *g* G, *d* D, &c. Let these lines represent so many scales of the octave, so placed that the points C, *g*, *d*, &c. may represent the points C, *g*, *d*, &c. of the circular scale in fig. 1. where it is cut by the dotted lines representing the system of mean tones and limmas. Then, 1*st*, take a certain length *d* G on the first line, to the right hand of the line CE, to represent a quarter of a comma. G will mark the place of the perfect Vth, while *g* represents that of the mean or tempered Vth. 2*dly*, Set off *d* D, double of *g* G, in like manner, to the right hand on the second parallel. This will be the place of the perfect IId to the key note C. 3*dly*, Also set off *a* A, on third parallel, to the left hand, equal to *g* G. This will mark the place of A, the VIth to the key note C. 4*thly*, Place E on the point *e*, because, in the system of mean tones represented in fig. 1. the IIIds were kept perfect. 5*thly*, Make *b* B, to the right hand on the fifth line, equal to *g* G, to mark the place of the perfect VIIth to the key note C. And, 6*thly*, make *t* T, to the right hand on the sixth line, equal to twice *g* G. This will serve for shewing the contemporaneous temperament of the tritone, or IVth, contained between F and B, as also of its complement, the false 5th in fig. 1.

It is evident that the temperament of all the notes of the octave, according to the above mentioned system, are properly represented in this figure. The Vth is tempered flat by the quarter comma G*g*; the IId is tempered flat by the half comma D*d*; the VIth is tempered sharp by a quarter comma A *a*; the IIId is perfect; the VIIth is flat by a quarter comma B*b*; and the 4th is sharp b[y a] quarter comma G*g*.

Now, let any other straight line C *t'* be drawn from C across these parallels. This will mark, by the intervals *g'*G, *d'*D, &c. the temperaments of another system of mean tones and limmas. For it is evident, that the contemporaneous variations *g g'*, *d d'*, &c. from the former temperament, are in the just proportions to each other; *g g'* being $= - v$, the variation proper for the Vth, and the opposite temperament for its complement or 4th. In like manner, *a a'* is $= 3\ v$, the variation competent to the VIth; and E *e'* is $= 4\ v$, the proper variation for the IIId.

75 The temperer.

In like manner, *b b'* is $= 5\ v$, the variation of the VIIth and 2d. And, lastly, *t t'* is the variation $6\ v$ of the tritone, and its complement, the false fifth.

For all these reasons, any straight line C*e'* or C*e''*, drawn from C across the parallels, may justly be called the TEMPERER.

76

This is a very useful construction: For it is plain, that the sounds which can be placed in our organs and harpsichords, which have only twelve keys for an octave, must approach to a system of mean tones. The division of the octave into twelve equal intervals is such a system of mean tones exactly. Now, in such systems, when a line is drawn from C across the parallels, we see, at one glance, not only all the temperaments of the notes with the key note, but also the temperaments of those concords which the notes employed in full harmony make with each other. Thus, in the harmony of K — III — V, the III and V make a minor 3d with each other; and in the harmony of K — 4 — VI, the 4 and VI make a major 3d with each other. Now the reader will easily see, that the first of these concords has its interval diminished on both sides, when the III is tempered sharp, but only on one side when it is tempered flat. The mathematical reader will also easily see, that the contemporaneous temperament A *a'* of the VIth is always equal to the sum *g'*G and E*e'*, and that A *a''* is equal to the difference of *g''*G and E*e''*. Therefore the temperament of this subordinate concord, in the full harmony K — III — V, is in all cases, the same with the contemporaneous temperament of the VIth.

In like manner, he will perceive that the temperament of the subordinate IIId, in the harmony of K — 4 — VI, is equal to the contemporaneous temperament of the III.

We also see, in general, that the whole harmony is more hurt when the temperer lies in the angle ECK, with the IIId tempered sharp, than when it is in the angle ACE, when the IIId is flat; and that the sum of all the temperaments of the concords with the key is the smallest when the IIIds are perfect. This system of mean tones, with perfect IIIds, would therefore be the best, if the harmony of different concords were equally hurt by the same temperament.

77 Certain scales of great u[se].

We do not know any thing that has been published on the science of music that gives more general and speedy instruction than this simple figure. If it be drawn of such a size as to allow the comma EK to be divided into a number of equal parts, sufficiently sensible, all trouble of calculation will be saved.

We would therefore propose to accompany this figure with proper scales.

The *first* scale should have G*g* divided into $13\frac{1}{2}$ parts. This will express the logarithmic measures of the temperaments mentioned in n° 63. a comma being $= 54$.

The *second* scale should have *g*G divided into 36 parts. This

This gives the beats made in 16 feconds by the notes c, g, when tempered by any quantity Gg'.

The *third* fcale fhould have gG divided into 60 parts, for the beats made by the notes c, e, or the notes c, $\bar{a}$.

The *fourth* fcale fhould have gG divided into 72 parts. This gives the beats made by the key note C, with its minor third e^{b}.

The *fifth* fcale fhould have gG divided into 48 parts, for the beats made by the notes c, f.

The *fixth* fcale fhould have gG divided into 89 parts, on which Aa' is meafured, to get the beats of the fubordinate concord formed by g and e in the harmony of K — III — V.

And, *laftly*, gG, divided into 80 parts, will give the beats made by f and $\bar{a}$ in the harmony of K — 4 — VI.

We are ignorant of the immediate efficient caufes of the pleafure we receive from certain confonances, and fhould therefore receive, with fatisfaction, any thing that can help us to approximate to a meafure of its degrees. We know that, in fact, the pleafantnefs of any individual concord increafes as the undulations called *beats* diminifh in frequency. It is probable that we fhall not deviate very far from the truth, if we fuppofe the harmonioufnefs of an individual tempered concord to be proportional to the flownefs of thefe undulations. But it by no means follows, that a tempered Vth and a IId are equally pleafant, each in its kind, when they beat equally flow. There is a difference *in kind* in the pleafures of thefe concords: and this muft arife from the peculiar manner in which the component pulfes of each concord divide each other. We are certain that this is all the difference that obtains between them in Nature. But the harmonioufnefs here fpoken of is the arrangement which produces this pleafure. We are intitled to fay, that this is equal in two given inftances, when the arrangements are precifely fimilar; and when the things arranged are the fame, nothing feems to remain in which the inftances can differ.

At any rate, it is of confequence to be able to proportion and diftribute thefe undulations at pleafure. They are unpleafant; and when reinforced by uniting, muft be more fo. The theory puts it in our power to prevent this union: perhaps by making them very unequal; or, if this fhould give a chance of periodical accumulation, we may find it better to make them all equal. Surely to have all this in our power is very defirable; and this is obtained by the theory of the beats of imperfect confonances.

But we are forgetting the procefs of tuning, and have only tuned three or four notes of our octave. We muft tune the reft by confidering their relation to notes already tuned. Thus, if $g\,c$ makes 36 beats in 16 feconds, F c fhould make one third lefs, or about 24 in the fame time; becaufe N in the formula is now 160 inftead of 240. Proceeding in this way, we fhall tune the octave C $\bar{\bar{c}}$ moft accurately as a fyftem of mean tones with perfect IIIds, by making the notes beat as follows. A point is put over the note that is to be tuned from the other, and a +, or a —, means that the concord is to be tempered fharp or flat. Thus g is tuned from c,

Make $c\dot{g}$	beat	—	36 times in 16 feconds
$G\dot{c}$		+	36
$G\dot{d}$		—	27, *i. e.* $\frac{3}{4}$ths of $g\,c$

Make $c\dot{f}$		—	48
$c\dot{\bar{a}}$	beat	+	60 times in 16 feconds
$c\dot{e}$			0, *i. e.* a perfect IIId
$d\dot{f}$♯			0
$e\dot{g}$♯			0
$a\dot{\bar{c}}$♯			0
$\dot{b}^{b}f$ downward		—	24, *i. e.* $\frac{8}{9}$ths of $c\,g$
$b^{b}\dot{\bar{b}}^{b}$			0, *i, e.* a perfect octave
$\bar{b}^{b}\dot{e}^{b}$ downward		—	43, *i. e.* $\frac{6}{5}$ths of $c\,g$
$C\dot{\bar{c}}$			0 an octave.

Other proceffes may be followed, and perhaps fome of them better than the procefs here propofed. Thus, b^{b} and e^{b} may be tuned as perfect IIIds to d and g downwards. Alfo, as we proceed in tuning, we can prove the notes, by comparing them with other notes already tuned, &c. &c. &c.

Temperament of the Scale of Mufic.

We have directed to tune the two notes b^{b} and e^{b} by taking the leading Vth downwards. We fhould have come at the fame pipes in the character of a♯ and d♯ in the procefs of tuning upwards by Vths. But this would not have produced precifely the fame founds, although, in our imperfect inftruments, one key muft ferve for a♯ and b^{b}. By tuning them as here directed, they are better fitted for the places in which they will be moft frequently employed in our ufual modulations. 80

Another fyftem very fit for our inftruments.

It may reafonably be afked, Why fo much is facrificed in order to preferve the IIIds perfect? Were they allowed to retain fome part of the fharp temperament that is neceffary for preferving the Vths perfect, we fhould perhaps improve the harmony. And fince enlarging the fifth makes the tone greater, and therefore the limma *mi fa* much fmaller, it will bring it nearer to the magnitude of a half tone; and this will be better fuited for its double fervice of the fharp of the note below, and the flat of the note above. Accordingly, fuch a temperament is in great repute, and indeed is generally practifed, although the VIth and the fubordinate chords of full harmony are evidently hurt by it. Even Dr Smith recommends it as well fuited to our defective inftruments, and gives an extremely eafy method of executing it by means of the beats. His method is to make the Vth and IIId beat equally faft, along with the key, the Vth flat, and the IIId fharp. He demonftates (on another occafion), that concords beat equally faft with the fame bafs when their temperaments are inverfely as the major terms of their perfect ratios. Therefore draw EG, and divide it in p, fo that Ep may be to pG as 3 to 5. Then draw Cp, cutting gG in g', and EK in e'; and this temperer will produce the temperament we want. It will be found, that Ee' and Gg' are each of them 32 of their refpective fcales. Fig. 2.

Therefore make	$c\,g$	beat 32 times in 16 feconds
	$G\,c$	32
	$G\,d$	24
	$G\,b$	24, and tune $b\,\bar{b}$
	$d\,\bar{a}$	36, and tune $a\,\bar{a}$
	$d\,f$♯	36
	$a\,e$	27
	$a\,\bar{c}$♯	27
	$e\,\bar{b}$	$40\frac{1}{2}$, proving $b\,\bar{b}$
	$e\,g$♯	$40\frac{1}{2}$

Therefore make F c $21\frac{1}{3}$, and tune F f
F a beat $21\frac{1}{3}$, proving a
$b^{\flat} f$ $28\frac{1}{3}$, and tune $b^{\flat}\ \overline{b^{\flat}}$
$e^{\flat}\ \overline{b^{\flat}}$ $38\frac{1}{3}$,
$c\ \overline{c}$ 0.

It may be proper to add to all these inſtructions a caution about the manner of counting the clock while the tuner is counting the beats. If this is to continue for 16 ſeconds, let the perſon who counts the clock ſay *one* at the beat he begins with, and then telling them over *to himſelf*, let him ſay *done* inſtead of 17. Thus 16 intervals will elapſe while the tuner is counting the beats. Were he to begin to count at *one*, and ſtop when he hears ſixteen, he would get the number of beats in 15 ſeconds only.

81. We do not heſitate to ſay, that this method of tuning by beats is incomparably more exact than by the mere judgment of the ear. We cannot miſtake more than one beat. This miſtake in the concord of the Vth amounts to no more than $\frac{1}{108}$th of a comma; and in the IIId it is only $\frac{1}{180}$.

82 Practical instructions. It may be objected that it is fit only for the organ and inſtruments of continued ſounds, but will not do for the quickly periſhing ſounds of the harpſichord. True, it is the only method worthy of that noble inſtrument, and this alone is a title to high regard. But farther; the accuracy attainable by it, renders it the only method fit for the examination of ſyſtems of temperament. Even for the harpſichord it is much more exact, and more certain in its proceſs, than any other. It does not proceed by a random trial of a flattened ſeries of Vths, and a compariſon with the reſulting IIId, and a ſecond trial, if the firſt be unſatisfactory. It ſays at once, let the Vth beat ſo many times in 16 ſeconds. Even in the ſecond method, without counting, and merely by the quality of the beats of the Vth and IIId, the progreſs is eaſy. Both are tuned perfect. The Vth is then flattened a little, and the IIId ſharpened;—if the Vth beat faſter than the IIId, alter it firſt.

All difficulty is obviated by the ſimple contrivance of a variable pendulum, already deſcribed. This may be made exact by any perſon that will take a little pains; and when once made will ſerve for every trial. When the ball is ſet to the proper number, and the pendulum ſet a ſwinging, we can come very near the truth by a very few trials.

N. B. In tuning a piano forte, which has always two ſtrings to a key, we muſt never attempt tuning them both at once; the back uniſon of both notes of the concord muſt be damped, by ſticking in a bit of ſoft paper behind it.

We hope that the inſtructions now given, and the application of them to two very reſpectable ſyſtems of temperament, are ſufficient for enabling the attentive reader to put this method of tuning ſucceſsfully in practice, and that he perceives the efficiency of it for attaining the deſired end. But before we take leave of it, we beg leave to mention another circumſtance, which evinces the juſt value of the general theory of the beats of imperfect conſonances as delivered by Dr Smith.

83 Origin of the Tartinian ſounds. Theſe reinforcements of ſound, which are called *beatings*, are noiſes. If any noiſe whatever be repeated, with ſufficient frequency, at equal intervals, it becomes a muſical note, of a certain determinate pitch. If it recur 60 times in a ſecond, it becomes the note C *fa ut*, or the double octave below the middle C of our harpſichords, or the note of an open pipe eight feet long. Now there is a ſimilar (we may call it the very ſame) reinforcement of ſound in every concord. Where the pulſe of one ſound of the concord biſects the pulſe of the other, the two ſounds are more uniformly ſpread: but where they coincide, or almoſt coincide, the condenſation of one undulation combines with that of the other, and there comes on the ear a ſtronger condenſation, and a louder ſound. This may be called a *noiſe*; and the equable and frequent recurrence of this noiſe ſhould produce a muſical note. If, for inſtance, c and a are ſounded together: There is this noiſe at every third pulſe of c, and every fifth pulſe of a; that is, 80 times in a ſecond. This ſhould produce a note which is a 12th below c, and a 17th major below a; that is, the double octave below f, which makes 320 vibrations in a ſecond. That is to ſay, along with the two notes c and a of the concord, and the compound ſound, which we call the *concord of the VIth*, we ſhould hear a third note FF in the baſs. Now this is known to be a fact, and it is the grave harmonic obſerved by Romieu and Tartini about the year 1754, and verified by all muſicians ſince that time. Tartini prized this obſervation as a moſt important diſcovery, and conſidered it as affording a foundation for the whole ſcience of muſic. We ſee that it is all included in the theory of beats publiſhed five years before, namely, in 1749; and every one of theſe grave harmonics, or Tartinian ſounds, as they have been called, are immediate conſequences of this theory. The ſyſtem of harmonious compoſition which Tartini has, with wonderful labour and addreſs, founded on it, has therefore no ſolidity. It is, however, preferable to Rameau's, becauſe it proceeds on a fact founded on the nature of muſical ſounds; whereas Rameau's is a mere whim, proceeding on a falſe aſſumption; namely, "that a muſical ſound is eſſentially accompanied by its octave, 12th, and 17th *in alto*."—This is not true, though ſuch accompaniment be very frequent, and it be very difficult to prevent it. Mr Rameau ought to have ſeen this. Are theſe acute harmonics muſical ſounds or not? He ſurely will not deny this. Therefore they, too, are eſſentially accompanied by *their* harmonics, and this abſolutely and neceſſarily *ad infinitum*; which is certainly abſurd. We ſhall have a better occaſion for conſidering this point when we deſcribe the *Trumpet Marigni* in a future article.

We have taken notice of only two ſyſtems of temperament; both of them are ſyſtems of mean tones, and are in good repute as practicable methods. It would be almoſt an endleſs taſk to mention all the ſyſtems of temperament which have been propoſed. Dr Smith, after having, with great ingenuity, appreciated the changes of harmoniouſneſs that are induced on the different concords by the ſame temperament, and having aſſigned that proportion of temperament which renders them equally harmonious, each in its kind, gives a ſyſtem of temperament, which he calls EQUAL HARMONY. Each concord (excepting the octave) is tempered in the inverſe proportion of the product of the terms of its perfect ratio. It is very nearly equivalent to a diviſion of the octave into 50 equal parts. We do not give any farther account of it here, although we think its harmony 84 Dr Smith's ſyſtem of EQUAL HARMONY.

[Tempera-ment of the Scale of Music.] harmony preferable to any thing that we have ever heard. We heard it, as executed for him, and under his inspection, by the celebrated harpsichord-maker Kirkmann, both when the instrument was yet in the hands of the maker, and afterwards by the ingenious author. We have also heard some excellent musicians declare, that the organ of Trinity college chapel at Cambridge was greatly improved in its harmony by the change made on its temperament under the inspection of Dr Smith. When we name Stanley, we presume that the authority will not be disputed. We mention this, because the writer in the Philosophical Transactions speaks of this system, with flattened major thirds, as of no value. But we do not give any farther account of it, because it is not suited to our instruments, which have but twelve sounds in the octave.

85 The reader will please to recollect, that the great object of temperament is twofold. First, to enable us to transpose music from one pitch to another, so that we may make any note of the organ the fundamental of the piece. This undoubtedly requires a system approaching to one of mean tones, because the harmony must be the same in every key. This requires temperament, because a sound must be occasionally considered, either as the sharp of the note below it, or the flat of the one above. This cannot produce perfect harmony, because the limma of the perfect diatonic scale is greater than a half tone. Thus a temperament is necessary merely for the sake of the melody. But, *secondly*, the nature of modern music requires every note to be accompanied, or considered as accompanied, with full harmony. This is, in fact, the same thing with modulating on every different note as a fundamental; but it requires a much closer attention to the perfection of the intervals, because a defect or excess in an interval that would scarcely offend the ear, if the notes were heard in succession, is quite intolerable when they are sounded together. Here the difference between the major and minor tone is of almost as great moment as the difference of the limma from a semitone. The second object, therefore, is to obtain, in the compass of three octaves, as many good concords of full harmony; that is, consisting of a fundamental with its major third and its fifth, erect or inverted, as possible. There is no other harmony, although our notes have frequently a different situation and appearance.

86 [Maxims of temperament very gratuitous.] It is no wonder that, in a subject where we are yet to seek for a principle, the attempts to attain this object have been very various, and very gratuitous. The mathematicians, even in modern times, have allowed themselves to be led away by fancies about the simplicity and consequent perfection of ratios; and having no clear principle, it is no wonder that some of their deductions are contrary to experience. According to Euler, those ratios which are most perfect, that is, most simple, admit of least temperament. The octave is therefore infinitely perfect; for it is allowed by all, that it must not have the smallest temperament. A Vth must be less tempered than a IIId. Even the practical musician thinks that he has tempered these two concords equally, when the offensive quality of each is made equally so; but in this case it is demonstrable, that the Vth has been much more tempered than the IIId. But this could not be discovered till we got the theory of beats.

Most of the mathematical musicians adhered to systems of mean tones; or, which are equivalent to such systems, giving similar harmonies on every key of the harpsichord. This is surely the most natural, and is peculiarly suggested by the transposing of music from one pitch to another: but they differ exceedingly, and without giving any convincing arguments, in their estimation of the effects of the same temperament on different concords. Much of this, we apprehend, arises from disposition. Persons of a gay disposition relish the harmony of the IIId, and prefer a sharp to a flat temperament of this concord. Persons of a more pensive disposition, prefer such temperaments as allow the minor thirds to be more perfect. [Tempera-ment of the Scale of Music.]

But there are many, eminent both as performers and as theorists, who reject any system which gives the same harmonies on every note of the octave. They observe, that in the progress of the cultivation of music in Europe, the melodies of all nations have gradually approached to a certain uniformity. Certain cadences, closes, strains, and phrases, are becoming every day more common; and even in the conduct of a considerable piece of music, and the gradual but slow passage of the modulation from one key into another, there is a certain regularity. Nay, they add, that this cannot be greatly deviated from without becoming very offensive. We may remain ignorant of the cause of this uniformity; but its existence seems to prove that it arises from some natural principle; and therefore it ought to be complied with, and our temperaments should be accommodated to it. The result of this uniformity in the music of our times is, that the modulation on some keys is much less frequent than on others, and this frequency decreases in a certain order. Supposing that we begin on C. A piece of plain music seldom goes farther than G and F. A little more fancy and refinement leads the composer into D, or into B^b, &c. &c. It would therefore be desirable to adjust our temperaments so, that the harmonies in C shall be the best possible, and gradually less perfect in the order of modulation. Thus we shall, in our general practice, have finer harmony than if it were made equal throughout the octave; because the unavoidable imperfections are thrown into the least frequented places of the scale. The practical musicians add to this, that by such a temperament the different keys acquire characters, which fit each of them more particularly for the expression of different sentiments, and for exciting different emotions. This is very perceptible in our harpsichords as they are generally tuned. The major key of A is remarkably brilliant; that of F is as remarkably simple, &c. 87 [Equal harmony rejected]

We cannot say that we are altogether convinced by these arguments. The violin is unquestionably the instrument of the greatest powers. A concert of instruments of this kind, unembarrassed by the harpsichord, or any instruments incapable of occasional temperament, is the finest music we have. The performers make no such degradations of harmony, but keep it as perfect as possible throughout; and a violin performer is sensible of violence and constraint when he accompanies a keyed instrument into these unfrequented paths. Let him play the same music alone, and he will play it quite differently, and much more to his own satisfaction. We imagine, too, that much of the uniformity spoken of is the result of imitation and fashion, and even of the tem-

 peraments

peraments that we have preferred. There is an evident distinction in the native music of different nations. An experienced musician will know, from a few bars, whether an air is Irish, Scotch, or Polish. This distinction is in the modulation; which, in those nations, follows different courses, and should therefore, on the same principle, lead to different temperaments.

With respect to the variety of characters given to the different keys, we must acknowledge the fact. We have tuned a piano forte in the usual manner; but instead of beginning the process with C, we began it with D. An excellent performer of voluntaries sat down to the instrument, and began to indulge his rich fancy; but he was confounded at every step; he thought the instrument quite out of tune. But when he was informed how it had been tuned, and then tried a known plain air on it, he declared it to be perfectly in tune. It is still very doubtful, however, whether we should not have much finer music, by equalising the harmony in the different keys, and trusting for the different expression so much spoken of to a judicious mixture of other notes called *discords*.

88 Cause of this uncertainty now removed by Dr Smith's theory.

After all, the great uncertainty about the most proper temperament has remained so long undetermined, because we had no method of executing with certainty any temperament that was offered to the public. What signifies it on what principle it may be proper to flatten a Vth one-fifth of a comma, and sharpen a VIth one-seventh of a comma, unless we are able to do both the one and the other? Till Dr Smith published the theory of beats, the monochord was the only assistance we had: but however nicely it may be divided, it is scarcely possible to make the moveable bridge so steady and so accurate in its motion, that it will not sensibly derange the tension of the string. We have seen some very nice and costly monochords; but not one of them could be depended on to one-eighth of a comma. Even if perfect, they give but momentary sounds by pinching. The bow cannot be trusted, because its pressure changes the tension. Mr Watt's experiments with his monochord of continued sound shewed this evidently. A pitch-pipe with a sliding piston promises the greatest accuracy; but we are sadly disappointed, because the gradation of the piston cannot be performed by any mathematical rule. It must be pushed more than half way down to produce, the octave more than one-third to produce the Vth, &c. and this without any rule yet discovered. Thanks to Dr Smith we can now produce an instrument tuned exactly, according to any proposed system, and then submit it to the fair examination of musicians. Even the speculatist may now form a pretty just opinion of the merits of a system, by calculating, or measuring by such scales as we have proposed, the beats produced by the tempered concords in all parts of the octave. No one who has listened with attention to the rattling beats of a full organ, with its twelfth and sesquialter stops all sounding, will deny that they are hostile to all harmony or good music. We cannot be much mistaken in preferring any temperament in proportion as it diminishes the number of those beats. We should therefore examine them on this principle alone; attending more particularly to the beats of the third major, because these are in fact the loudest and most disagreeable; and we must not content ourselves with the beats of each concord with the fundamental of the full harmony, whether K—III—V, or K—4—VI, or K—3—V, or K—4—6, which sometimes occurs. We must attend equally to the beats of the two notes of accompaniment with each other: these are generally the most faulty.

This examination is neither difficult nor tedious. 89.
1. Write down, in one column, the lengths of the strings or divisions of the monochord; in another write their logarithms; in a third the remainders, after subtracting each from the logarithm of the fundamental. 3. Have at hand a similar table for the perfect diatonic scale. 4. Compare these, one by one, and note the difference, + or —, in a 4th column. These are the temperaments of each note of the scale. 5. Compare every couple of notes which will compose a major or minor third, or a fifth, by subtracting the logarithm of the one note from that of the other. The differences are the intervals tempered. 6. Compare these with the perfect intervals of the diatonic scale, and note the differences, + or —, and set them down in a fifth column. These are all the temperaments in the system. 7. If we have used logarithms consisting of five decimal places, which is even more than sufficient, consider these numeral temperaments as the q of the formula given in n° 65. for calculating the beats, and then p is always $= 540$. Or we may make another column, in which the temperaments are reduced to some easy fraction of a comma.

90 System of Dr Young.

We shall content ourselves with giving one example; the temperament proposed by Mr Young in the Philosophical Transactions for 1800. It is contained in the following table.

1.	2.	3.	4.	5.		
				IIIds upward on		
C	100000	5.00000		C	135	Sharp.
C♯	94723	4.97645	2355	G. F.	190	
D	89304	4.95087	4913	D. B♭	245	
E♭	83810	4.92330	7670	A. E♭	346	
E	79752	4.90174	9826	E. A♭	448	
F	74921	4.87461	12539	B. C♯	494	
F♯	71041	4.85151	14849	F♯	540	
G	66822	4.82492	17508	3ds upward on		
G♯	63148	4.80036	19964	A. E.	236	Flat.
A	59676	4.77580	22420	D. B.	291	
B♭	56131	4.74921	25079	G. F♯	346	
B	53224	4.72610	27390	C. C♯	448	
C	50000	4.69897	30103	F. G♯	494	
				B♭. E♭	540	

Vths upward on		
E♭. G♯. C♯. F♯	perfect	Flat.
F. B♭ E. B	46	
C. G. D. A	116	

Interval of a comma	540
minor third	7918
major third	9691
fifth	17609

The first column of the above table contains the ordinary designations of the notes. The second contains the corresponding lengths of the monochord. The third contains the logarithms of column second. The fourth contains the difference of each logarithm from the first. The next column contains, first, the temperaments of all the mpera- t of the ale of Iusic, || mplars.

the major thirds, having for their lowest note the sound corresponding to the letter. Thus 494, or $\frac{494}{540}$ of a comma, is the temperament of the IIId, B — D♯, and C♯ — F. Secondly, it contains all the minor thirds formed on the notes represented by the letters. The column below contains the temperaments of the Vths. *N. B.* These temperaments are calculated by the author. We have found some of them a little different. Thus we make the temperament of C — G only 108. Below this we have set down the measures of the perfect intervals, which are to be compared with the differences of the logarithms in column third.

91 em of iber-

We presume not to decide on the merits of this temperament: Only we think that the temperaments of several thirds, which occur very frequently, are much too great; and many instances of the 6th, which is frequent in the flat key, are still more strongly tempered. A temperament, however, which very nearly coincides with Dr Young's, has great reputation on the continent. This is the temperament by Mr Kirnbergher, published at Berlin in 1771, in his book called *Die Kunst des reinen Satzes in der Musik*. The eminent mathematician Major Templehoff has made some important observations on this temperament, and on the subject in general, in an essay published in 1775, Berlin. Dr Young's is certainly preferable.

The monochord is thus divided by Kirnbergher:

C =	1,0000	F =	7500	B♭ =	5625
C♯	9492	F♯	7111	B	5313
D	8889	G	6667	c	5000
E♭	8437	G♯	6328		
E	8000	A	5963		

We conclude this article (perhaps too long) by earnestly recommending to persons who are not mathematically disposed, the sliding scales, either circular or rectilineal, containing the octave divided into 301 parts; and a drawing of fig. 2. on card paper, of proper size, having the quarter comma about two inches, and a series of scales corresponding to it. This will save almost the whole of the calculation that is required for calculating the beats, and for examining temperaments by this test. To readers of more information, we earnestly recommend a careful perusal of Smith's Harmonics, second edition. We acknowledge a great partiality for this work, having got more information from it than from all our patient study of the most celebrated writings of Ptolemy, Huyghens, Euler, &c. It is our duty also to say, that we have got more information concerning the music of the Greeks from Dr Wallis's appendix to his edition of Porphyrius's Commentary on Ptolemy's Harmonics, than from any other work.

TEMPIE, a place in New Galicia, 200 leagues N. W. of the city of Mexico.—*Morse.*

TEMPLARS. In the account of this order, which is published in the *Encyclopædia*, we have, with many others, supposed that the guilt of which they were accused at the suppression of the order was less enormous than their enemies alleged. For the honour of human nature, we are still unwilling to believe that this was not the case. Justice, however, compels us to admit, that the Abbé Barruel has brought together such a cloud of witnesses against the Templars, that we know not how to resist their evidence; and that he has completely proved, that *Philip le Bel* was not influenced by avarice when he suppressed that order in France. "It has been said, that he and Clement V. had concerted between them the dissolution of the Templars. The falsity of such an assertion is evident on the inspection of their letters. Clement V. at first will give no credit to the accusations against the Templars; and even when he receives incontestable proofs from Philip le Bel, he had still so little concerted the plan with that Prince, that every step taken by the one or the other occasions disputes on the rights of the church or of the throne.

Templars.

"It was also said, that the king wished to seize on the great riches of these knights: but at the very commencement of his proceedings against the order, he solemnly renounced all share in their riches; and perhaps no Prince in Christendom was truer to his engagement. Not a single estate was annexed to his domain; and all history bears testimony to the fact.

"We next hear of a spirit of revenge which actuated this Prince; and during the whole course of this long trial, we do not hear of a single personal offence that he had to revenge on the Templars. In their defence, not the most distant hint, either at the revengeful spirit, or at any personal offence against the king, is given; so far from it, until the period of this great catastrophe, the grand master of the order had been a particular friend of the king's, who had made him godfather to one of his children.

"In fine, the rack and torture is supposed to have forced confessions from them which otherwise they never would have made; and in the minutes, we find the avowal of at least 200 knights all made with the greatest freedom, and without any coercion. Compulsion is mentioned but in the case of one person, and he makes exactly the same avowal as 12 other knights, his companions, freely made (A). Many of these avowals were made in councils where the bishops begin by declaring, that all who had confessed through fear of the torture should be looked upon as innocent, and that no Knight Templar should be subjected to it (B). The Pope Clement V. was so far from favouring the king's prosecutions, that he began by declaring them all to be void and null. He suspended the archbishops, bishops, and prelates, who had acted as inquisitors in France. The king accuses the Pope in vain of favouring the Templars; and Clement is only convinced after having been present at the interrogatories of 72 knights at Poictiers, in presence of many bishops, cardinals, and legates. He interrogated them, not like a judge who sought for criminals, but like one who wished to find innocent men, and thus exculpate himself from the charge of having favoured them. He hears them repeat the same avowals, and they are freely confirmed. He desired that these avowals should be read to them after an interval of some days, to see if they would still freely persevere in their depositions. He hears them all confirmed. *Qui perseverantes in illis, eas expresse et sponte prout recitatæ fuerant approbârunt.* He wished still further to interrogate

(A) *Layette*, N° 20. *Interrog. made at Caen.*
(B) See the *Council of Ravenna. Rubeus Hist. Raven.* lib. vi.

Templars.

gate the grand master and the principal superiors, *præceptores majores*, of the divers provinces of France, Normandy, Poitou, and of the Transmarine countries. He sent the most venerable persons to interrogate those of the superiors, whose age or infirmities hindered them from appearing before him. He ordered the depositions of their brethren to be read to them, to know if they acknowledged the truth of them. He required no other oath from them than to answer freely and without compulsion; and both the grand master and the superiors of these divers provinces depose and confess the same things, confirm them some days after, and approve of the minutes of their depositions taken down by public notaries. Nothing less than such precautions could convince him of his error: it was then only that he revoked his menaces and his suspension of the French bishops, and that he allows the king to proceed in the trials of the Templars.

"Let such pretexts be forgotten, and let us only dwell on the avowals which truth alone forced from these criminal knights.

"Their depositions declare, that the Knights Templars, on their reception, denied Christ, trampled on the cross, and spit upon it; that Good Friday was a day which was particularly consecrated to such outrages; that they promised to prostitute themselves to each other for the most unnatural crimes; that every child begotten by a Templar was cast into the fire; that they bound themselves by oath to obey, without exception, every order coming from the grand master; to spare neither sacred nor prophane; to look upon every thing as lawful when the good of the order was in question; and, above all, never to violate the horrible secrets of their nocturnal mysteries, under pain of the most terrible chastisements (c).

"In making their depositions, many of them declared they had only been forced into these horrors by imprisonment and the most cruel usage; that they wished, after the example of many of their brethren, to pass into other orders, but that they did not dare, fearing the power and vengeance of their order; that they had secretly confessed their crimes, and had craved absolution. In this public declaration, they testified, by their tears, the most ardent desire of being reconciled to the church.

"All repeat the same deposition, except three, who declare they have no knowledge of the crimes imputed to their order. The Pope, not content with this information taken by men of religious orders and by French noblemen, requires that a new trial should take place in Poitou before cardinals and others whom he himself nominates: Again, with the same freedom, and for the third time, the grand master and other chiefs, in presence of Clement V. repeat their depositions. Molay even requested, that one of the lay brothers, who was about his person, should be heard, and this brother confirms the declaration. During many years these informations were continued and renewed at Paris, in Champagne, in Normandy, in Quercy, in Languedoc, in Provence. In France alone, above 200 avowals of the same nature are to be found: nor did they vary in England, where, at the synod of London held in 1311, 78 English knights were heard, and two whole months were spent in taking informations and in verifying their declarations. Fifty-four Irish were also heard, and many Scotch, in their respective countries. It was in consequence of these declarations that the order of the Templars was abolished in those kingdoms, and that the parliament disposed of their goods (d). The same declarations were taken and proved in Italy, at Ravenna, at Bologna, at Pisa, and at Fiorence, though in all these councils the prelates were very ready to absolve all those knights who could succeed in their justifications.

Templars ‖ Templeman.

"I would willingly assert (continues the Abbé), that it was the smaller part of the Templars who suffered themselves to be carried away by such abominations. Some even at Paris were declared innocent. In Italy a still greater number were absolved; of all those who were judged at the councils of Mayence and Salamanca none were condemned: and hence we may conclude, that of the 9000 houses belonging to the order, many had not been tainted, and that whole provinces were to be excepted from the general stain of infamy. But the condemnations, the juridical depositions, the method of initiating the knights, almost became general; the secrecy of their receptions, where neither prince, nor king, nor any person whatever, could be present during the last half century, are so many testimonies which corroborate the divers accusations contained in the articles sent to the judges; that is to say, that at least two thirds of the order knew of the abominations practised without taking any steps to extirpate them. *Quod omnes, vel quasi duæ partes ordinis scientes dictos errores corrigere neglexerint.*

"This certainly cannot mean that two thirds of the knights had equally partaken of these abominations. It is evident, on the contrary, that many detested them as soon as they were acquainted with them; and that others only submitted to them, though initiated, after the harshest treatment and most terrible threats. Nevertheless, this proves, that the greatest part of these knights were criminal, some through corruption, others through weakness or connivance; and hence the dissolution of the order became necessary."

TEMPLE, a township of New-Hampshire, Hillsborough county, N. of New-Ipswich, and 70 miles westerly of Portsmouth. It was incorporated in 1768, and contains 520 inhabitants.—*Morse.*

Temple *Bay*, on the Labrador coast, opposite Belle Isle. A British settlement of this name was destroyed by the French, in October, 1796.—*ib.*

TEMPLEMAN (Peter), M. D. the son of an eminent attorney at Dorchester in the county of Dorset, by Mary daughter of Robert Haynes, was born March 17, 1711, and was educated at the Charter-house (not on the foundation), whence he proceeded to Trinity-college, Cambridge, and there took his degree of B. A. with distinguished reputation. During his residence at Cambridge, by his own inclination, in conformity with that of his parents, he applied himself to the study of divinity, with a design to enter into holy orders; but after some time, from what cause we know not, he altered

Biog. Dict.

(d) Vide *Valsinger in Edvardum* II. *et Ypodigma Neustriæ apud Dupuy.—Essai de Fred. Nicolai.*

tered his plan, and applied himself to the study of physic. In the year 1736, he went to Leyden, where he attended the lectures of Boerhaave, and the professors of the other branches of medicine in that celebrated university, for the space of two years or more. About the beginning of 1739, he returned to London, with a view to enter on the practice of his profession, supported by a handsome allowance from his father. Why he did not succeed in that line was easy to be accounted for by those who knew him. He was a man of a very liberal turn of mind, of general erudition, with a large acquaintance among the learned of different professions, but of an indolent, inactive disposition; he could not enter into juntos with people that were not to his liking; nor cultivate the acquaintance to be met with at tea-tables; but rather chose to employ his time at home in the perusal of an ingenious author, or to spend an attic evening in a select company of men of sense and learning. In this he resembled Dr Armstrong, whose limited practice in his profession was owing to the same cause. In the latter end of the year 1750 he was introduced to Dr Fothergill by Dr Cumming, with a view of instituting a Medical Society, in order to procure the earliest intelligence of every improvement in physic from every part of Europe. At the same period he tells his friend, " Dr Mead has very generously offered to assist me with all his interest for succeeding Dr Hall at the Charter-house, whose death has been for some time expected. Inspired with gratitude, I have ventured out of my element (as you will plainly perceive), and sent him an ode." Dr Templeman's epitaph on Lady Lucy Meyrick (the only English copy of verses of his writing that we know of), is printed in the eighth volume of the " Select Collection of Miscellany Poems, 1781." In 1753 he published the first volume of " Curious Remarks and Observations in Physic Anatomy, Chirurgery, Chemistry, Botany, and Medicine; extracted from the History and Memoirs of the Royal Academy of Sciences at Paris;" and the second volume in the succeeding year. A third was promised, but we believe never printed. It appears, indeed, that if he had met with proper encouragement from the public, it was his intention to have extended the work to twelve volumes, with an additional one of index, and that he was prepared to publish two such volumes every year. His translation of " Norden's Travels" appeared in the beginning of the year 1757; and in that year he was editor of " Select Cases and Consultations in Physic, by Dr Woodward," 8vo. On the establishment of the British Museum, in 1753, he was appointed to the office of keeper of the reading room, which he resigned on being chosen, in 1760, secretary to the then newly instituted Society of Arts, Manufactures, and Commerce. In 1762, he was elected a corresponding member of the Royal Academy of Science of Paris, and also of the Œconomical Society at Berne. Very early in life Dr Templeman was afflicted with severe paroxysms of an asthma, which eluded the force of all that either his own skill, or that of the most eminent physicians then living, could suggest to him; and it continued to harass him till his death, which happened September 23, 1769. He was esteemed a man of great learning, particularly with respect to languages; spoke French with great fluency, and left the character of a humane, generous, and polite member of society.

TEMPLETON, a township in the N. W. part of Worcester county Massachusetts, containing 950 inhabitants. It was granted as a bounty to the soldiers in king Philip's war, and was called Narraganset N° 6, until its incorporation in 1762. It is 63 miles W. by N. W. of Boston, and 28 N. by W. of Worcester.—*Morse.*

TENCH'S *Island*, in the South Pacific Ocean, was discovered in 1790, by Lieut. Ball, and lies in lat. 1 39 S. and long. 151 31 W. It is low, and only about 2 miles in circuit, but is entirely covered with trees, including many of the cocoa-nut kind. It abounds with inhabitants, and the men appear to be remarkably stout and healthy.—*ib.*

TENERIFFE, a town of Santa Martha and Terra Firma, in S. America, situated on the eastern bank of the great river Santa Martha, below its confluence with Madalena, about 135 miles from the city of Santa Martha, towards the south, the road from which capital to Teneriffe is very difficult by land, but one may go very easily and agreeably from one to the other partly by sea, and partly by the above mentioned river.—*ib.*

TENNANT'S *Harbour*, on the coast of the District of Maine, lies about three leagues from George's Islands.—*ib.*

TENNESSEE, a large, beautiful, and navigable river of the State of Tennessee, called by the French *Cherokee*, and absurdly by others, Hogohegee river, is the largest branch of the Ohio. It rises in the mountains of S. Carolina, in about lat. 37, and pursues a course of about 1000 miles, south and south-west nearly to lat. 34, receiving from both sides a number of large tributary streams. It then wheels about to the north in a circuitous course, and mingles with the Ohio, nearly 60 miles from its mouth. It is navigable for vessels of great burden to the *Muscle Shoals*, 250 miles from its mouth. It is there about three miles broad, full of small isles, and only passable in small boats or batteaux. From these shoals to the *Whirl*, or *Suck*, the place where the river is contracted to the breadth of 70 yards, and breaks through the Great Ridge, or Cumberland Mountain, is 250 miles, and the navigation for large boats all the way excellent. The highest point of navigation upon this river is Tellico Block-House, 900 miles from its mouth according to its meanders. It receives Holston river 22 miles below Knoxville, and then running west 15 miles receives the Clinch. The other waters which empty into Tennessee, are Duck and Elk rivers, and Cow Creek on the one side; and the Occachappo, Chickamauga and Hiwassee rivers on the south and south-eastern sides. In the Tennessee and its upper branches are great numbers of fish, some of which are very large and of an excellent flavour. The river to which the name Tennessee was formerly confined, is that part of it which runs northerly, and receives Holston river 20 miles below Knoxville. The Coyeta, Chota, and Chilhawee Indian towns are on the west side of the river; and the Talassee town on the east side.—*ib.*

TENNESSEE, one of the United States of America, and, until 1796, called the *Tennessee Government*, or *Territory of the United States South of the Ohio*. It is in length 400 miles, and in breadth 104; between lat. 35 and 36 30 N. and long. 81 28 and 91 38 W. It is bounded N. by Kentucky and parts of Virginia; E. by North-Carolina; S. by Georgia; W. by the Mississippi. It is divided

Tenneffee. divided into 3 diftricts, viz. Wafhington, Hamilton, and Mero, which are fubdivided into 13 counties, viz. Wafhington, Sullivan, Greene, Carter, Hawkins, Knox, Jefferfon, Sevier, Blount, Grainger, Davidfon, Sumner, Robertfon, and Montgomery. The firft four belonging to Wafhington diftrict, the next five to that of Hamilton, and the four latter to Mero diftrict. The two former diftricts are divided from the latter, by an uninhabited country of 91 miles in extent; that is from the block-houfes, at the point formed by the junction of the river Clinch with the Tenneffee, called South-Weft Point, to Fort Blount upon Cumberland river, through which there is a waggon road, opened in the fummer of 1795. There are few countries fo well watered with rivers and creeks. The principal rivers are the Miffiffippi, Tenneffee, Cumberland, Holfton, and Clinch. The tract called the Broken Ground, fends immediately into the Miffiffippi, the Wolf, Hatchee, Forked-Deer, Obian or Obean, and Reelfoot; which are from 30 to 80 yards wide at their mouths; moft of the rivers have exceedingly rich low grounds, at the extremity of which is a fecond bank, as on moft of the lands of the Miffiffippi. Befides thefe rivers, there are feveral fmaller ones, and innumerable creeks, fome of which are navigable. In fhort, there is hardly a fpot in this country, which is upwards of 20 miles diftant from a navigable ftream. The chief mountains are Stone, Yellow, Iron, Bald, and Unaka, adjoining to one another, from the eaftern boundary of the State, and feparate it from N. Carolina; their direction is nearly from N. E. to S. W. The other mountains are Clinch and Cumberland. It would require a volume to defcribe the mountains of this ftate, above half of which is covered with thofe that are uninhabitable. Some of thefe mountains, particularly the Cumberland or Great Laurel Ridge, are the moft ftupendous piles in the United States. They abound with ginfeng and coal. The caverns and cafcades in thefe mountains are innumerable. The *Enchanted Mountain*, about two miles fouth of Brafs-Town, is famed for the curiofities on its rocks. There are on feveral rocks a number of impreffions refembling the tracks of turkies, bears, horfes, and human beings, as vifible and perfect as they could be made on fnow or fand. The latter were remarkable for having uniformly fix toes each; one only excepted, which appeared to be the print of a negro's foot. By this we muft fuppofe the originals to have been the progeny of Titan or Anak. One of thefe tracks was very large, the length of the foot 16 inches, the diftance of the extremes of the outer toes 13 inches, the proximate breadth behind the toes 7 inches, the diameter of the heel-ball 5. One of the horfe tracks was likewife of an uncommon fize, the tranfverfe and conjugate diameters, were 8 by 10 inches; perhaps the horfe which the Great Warrior rode. What appears the moft in favour of their being the real tracks of the animals they reprefent, is the circumftance of a horfe's foot having apparently flipped feveral inches, and recovered again, and the figures having all the fame direction, like the trail of a company on a journey. If it be a *lufus naturæ*, the old dame never fported more ferioufly. If the operation of chance, perhaps there was never more apparent defign. If it were done by art, it might be to perpetuate the remembrance of fome remarkable event of war, or engagement fought on the ground. The vaft heaps of ftones near the place, faid to be tombs of warriors flain in battle, feem to favour the fuppofition. The texture of the rocks is foft. The part on which the fun had the greateft influence, and which was the moft indurated, could eafily be cut with a knife, and appeared to be of the nature of the pipe ftone. Some of the Cherokees entertain an opinion that it always rains when any perfon vifits the place, as if fympathetic nature wept at the recollection of the dreadful cataftrophe which thofe figures were intended to commemorate. The principal towns are Knoxville, the feat of government, Nafhville, and Jonefborough, befides 8 other towns, which are as yet of little importance. In 1791, the number of inhabitants was eftimated at 35,691. In November, 1795, the number had increafed to 77,262 perfons. The foil is luxuriant, and will afford every production, the growth of any of the United States. The ufual crop of cotton is 800lbs. to the acre, of a long and fine ftaple; and of corn, from 60 to 80 bufhels. It is afferted, however, that the lands on the fmall rivers, that empty into the Miffiffippi, have a decided preference to thofe on Cumberland river, for the production of cotton, rice, and indigo. Of trees, the general growth is poplar, hickory, black and white walnut, all kind of oaks, buck-eye, beech, fycamore, black and honey locuft, afh, horn-beam, elm, mulberry, cherry, dogwood, faffafras, poppaw, cucumber-tree, and the fugar-tree. The undergrowth, efpecially on low lands, is cane; fome of which are upwards of 20 feet high, and fo thick as to prevent any other plant from growing. Of herbs, roots, and fhrubs, there are Virginia and Seneca fnakeroot, ginfeng, and angelica, fpice-wood, wild plum, crab-apple, fweet annife, red-bud, ginger, fpikenard, wild hop and grape vines. The glades are covered with wild rye, wild oats, clover, buffaloe grafs, ftrawberries and pea-vines. On the hills, at the head of rivers, and in fome high cliffs of Cumberland, are found majeftic red cedars; many of thefe are four feet in diameter, and 40 feet clear of limbs. The animals are fuch as are found in the neighbouring States. The rivers are well ftocked with all kinds of frefh water fifh; among which are trout, perch, cat-fifh, buffaloe-fifh, red-horfe, eels, &c. Some cat-fifh have been caught which weighed upwards of 100 pounds: the weftern waters being more clear and pure than the eaftern rivers, the fifh are in the fame degree more firm and favory to the tafte. The climate is temperate and healthful; the fummers are very cool and pleafant in that part which is contiguous to the mountains that divide this ftate from N. Carolina; but on the weftern fide of the Cumberland Mountain the heat is more intenfe, which renders that part better calculated for the production of tobacco, cotton and indigo. Lime-ftone is common on both fides of the Cumberland Mountain. There are no ftagnant waters; and this is certainly one of the reafons why the inhabitants are not afflicted with thofe bilious and intermitting fevers, which are fo frequent, and often fatal, near the fame latitude on the coaft of the fouthern States. Whatever may be the caufes, the inhabitants have been remarkable healthy fince they fettled on the waters of Cumberland river. The country abounds with mineral fprings. Salt licks are found in many parts of the country. Iron ore abounds in the diftricts of Wafhington and Hamilton, and fine ftreams to put iron-works in operation. Iron ore was lately difcovered upon the fouth of Cumberland

berland river, about 30 miles below Nafhville, and a furnace is now erecting. Several lead mines have been difcovered, and one on French Broad has been worked; the ore produced 75 per cent. in pure lead. The Indians fay that there are rich filver mines in Cumberland Mountain, but cannot be tempted to difcover any of them to the white people. It is faid that gold has been found here; but the mine from which that metal was extracted is now unknown to the white people. Ores and fprings ftrongly impregnated with fulphur are found in various parts. Saltpetre caves are numerous; and in the courfe of the year 1796, feveral tons of faltpetre were fent to the Atlantic markets. This country furnifhes all the valuable articles of the fouthern States. Fine waggon and faddle horfes, beef cattle, ginfeng, deer-fkins, and furs, cotton, hemp, and flax, may be tranfported by land; alfo iron, lumber, pork and flour may be exported in great quantities, now that the navigation of the Miffiffippi is opened to the citizens of the United States. But few of the inhabitants underftand commerce, or are poffeffed of proper capitals; of courfe it is as yet but badly managed. However, being now an independent State, it is to be hoped that the eyes of the people will foon be opened to their true intereft, and agriculture, commerce, and manufactures will each receive proper attention. The Prefbyterians are the prevailing denomination of Chriftians; in 1788, they had 23 large congregations, who were then fupplied by only 6 minifters. There are alfo fome Baptifts and Methodifts. The inhabitants have paid great attention to the interefts of fcience; befides private fchools, there are 3 colleges eftablifhed by law; Greenville in Green's county, Blount at Knoxville, and Wafhington in the county of that name. Here is likewife a "Society for promoting Ufeful Knowledge." A tafte for literature is daily increafing. The inhabitants chiefly emigrated from Pennfylvania, and that part of Virginia that lies weft of the Blue Ridge. The anceftors of thefe people were generally of the Scotch nation; fome of whom emigrated firft to Ireland, and from thence to America. A few Germans and Englifh are intermixed. In 1788, it was thought there were 20 white perfons to one negro; and the difproportion is thought to be far greater now. This country was included in the 2d charter of king Charles II. to the proprietors of Carolina. In a fubfequent divifion, it made a part of N. Carolina. It was explored about the year 1745, and fettled by about 50 families in 1754; who were foon after driven off or deftroyed by the Indians. Its fettlement re-commenced in 1765. The firft permanent fettlement took place near Long-Ifland of Holfton, and upon Watauga, about 1774; and the firft appearance of any perfons from it, in the public councils of N. Carolina, was in the convention of that State in 1776. In the year 1780, a party of about 40 families, under the guidance and direction of James Robertfon, (fince Brig. Gen. Robertfon of Mero diftrict) paffed through a wildernefs of at leaft 300 miles to the French Lick, and there founded Nafhville. Their neareft neighbours were the fettlers of the infant State of Kentucky, between whom and them, was a wildernefs of 200 miles. From the year 1784, to 1788, the government of N. Carolina over this country was interrupted by the affumed State of Frankland; but in the year 1789, the people returned to their allegiance. In 1789, N. Carolina ceded this territory to the United States, on certain conditions, and Congrefs provided for its government. A convention was held at Knoxville, in 1796, and on the 6th of February the conftitution of the State of Tenneffee was figned by every member of it. Its principles promife to enfure the happinefs and profperity of the people. The following are the diftances on the new road from Nafhville in Davidfon county, to Fort Campbell, near the junction of Holfton with the Tenneffee.

	Miles.
From Nafhville to Stoney river	9
Big Spring	6
Cedar Lick	4
Little Spring	6
Barton's Creek	4
Spring Creek	5
Martin's Spring	5
Blair's Spring	5
Buck Spring	12
Fountaines	8
Smith's Creek	6
Coney River	11
Mine Lick	9
Falling Creek	9
War Path	7
Bear Creek	18
Camp Creek	8
King's Spring	16
Grovet's Creek	7
The foot of Cumberland Mountain	2
Through the mountain to Emmery's river, a branch of the Pelefon	11
To the Pappa Ford of the Pelefon or Clinch river	12
To Campbell's Station, near Holftein	10
To the Great Ifland	100
To Abingdon in Wafhington county	35
To Richmond in Virginia	310
Total	635

By this new road, a pleafant paffage may be had to the weftern country with carriages, as there will be only the Cumberland mountain to pafs, and that is eafy of afcent; and beyond it, the road is generally level and firm, abounding with fine fprings of water. The Indian tribes within and in the vicinity of this State are the Cherokees and Chickafaws.—*ib.*

TENSAW, a fettlement near Mobile Bay, inhabited by 90 American families, that have been Spanifh fubjects fince 1783.—*ib.*

TEOWENISTA *Creek*, runs foutherly about 28 miles, then wefterly 6 miles, and empties into Alleghany river about 18 miles from its mouth, and nearly 5 below the Hickory town.—*ib.*

TEQUAJO, or *Tiquas*, a province of Mexico; according to fome Spanifh travellers, being about lat. 37, where they found 16 villages.—*ib.*

TEQUEPA, a part of the coaft of New Mexico, about 18 leagues N. W. of Acapulco.—*ib.*

TEQUERY *Bay*, on the fouth-eaft part of the coaft of the ifland of Cuba, between Cape Cruiz, and Cape Maizi, at the eaft end. It affords good anchorage and fhelter for fhips, but is not much frequented.—*ib.*

TERANE', a town in Egypt, fituated on what Mr Browne

Browne calls the *left* of the moſt weſtern mouth of the Nile, at a very ſmall diſtance from the river. Its latitude is 30° 24'. The buildings are chiefly unburned brick, though there are alſo ſome of ſtone. The town and diſtrict containing ſeveral villages, belonged, before the French invaſion, to Murad Bey, who uſually entruſted its government, and the collection of its revenue, to one of his Caſhefs. That revenue ariſes principally from natrôn (See Natrum, *Encycl.*), found in great quantities in certain lakes about thirty-five miles from Terané; and it is on account of theſe lakes only that the town is worthy of notice in this work; for though there are many columns in its neighbourhood, which indicate the ſcite of ancient ſtructures, none of them have inſcriptions aſcertaining their antiquity.

The eaſtern extremity of the moſt weſtern lake Mr Browne found to be 30° 31' North. No vegetation appears, except reeds, on the margin of the lake, which is very irregular in its form; ſo that it is not eaſy to ſay what may be the quantity of ground covered with water. It is higher in winter than in ſummer; and when it was viſited by our author, its breadth did not exceed a mile, though its length was nearly four. Towards the end of the ſummer, it is ſaid, theſe lakes are almoſt dry; and the ſpace that the water has retired from is then occupied by a thick depoſition of ſalt. Not far removed from the eaſtern extremity, a ſpring riſes with ſome force, which much agitates the reſt of the water. Cloſe to that ſpring the depth was far greater than Mr Browne's height; in other parts it was obſervable that it did not generally exceed three feet. The thermometer near this ſpring ſtood at 76, while in the open air it was 87. The more weſtern lake differs not materially from the eaſtern in ſize, form, or productions. The colour of the water in both is an imperfect red; and where the bottom is viſible, it appears almoſt as if covered with blood. Salt, to the thickneſs of five or ſix inches, lies conſtantly in the more ſhallow parts. The ſurface of the earth, near the lake, partakes more or leſs generally of the character of natrôn, and, in the parts fartheſt removed, offers to the foot the ſlight reſiſtance of ploughed ground after a ſlight froſt. The ſoil is coarſe ſand. The water of the lake, on the ſlighteſt evaporation, immediately depoſits ſalt. There is a mountain not far from the lakes, where natrôn is found in inſulated bodies, near the ſurface, of a much lighter colour than that produced in the lake, and containing a greater portion of alkali. How thick the ſubſtance of natrôn commonly is in the lake, our author did not accurately determine; but thoſe employed to collect it report, that it never exceeds a cubit, or common pike; but it appears to be regenerated as it is carried away. If ever it ſhould be brought to ſuperſede the uſe of barilla, the quantity obtainable ſeems likely to anſwer every poſſible demand.

TEREBRATULÆ (Anomiæ, *Lin.* ſee that article *Encycl.*) have been ſuppoſed not to exiſt now but as petrified ſhells. This, however is a miſtake. The anomia is an inhabitant of every region, and has exiſted in every age. As many terebratulæ were caught by Perouſe's people during his voyage of diſcovery, and as Lamanon the naturaliſt thought they ſhould be conſidered as a genus by themſelves, he has given us the following deſcription of the *anomia*, or, as he calls it, *terebratula*, on the coaſt of Tartary:

The length of the ſhell varies from ſix to twenty lines, and its breadth from five to eighteen; there are, however, conſiderable varieties of proportion between different individuals, beſides thoſe ariſing from the different ages of the animal. It would be improper, therefore, to diſtinguiſh the various ſpecies of anomiæ by the proportion of their ſhells. The waving lines on the edges of the ſhell are equally defective, as diſtinctive characters; for our author obſerved in the ſame ſpecies the ſhell approaching or receding indifferently from the circular form, and in ſome the edges of the valves are on the ſame plane; whereas in others, one of the valves forms a ſalient angle in the middle of its curve, and the other a re entering angle.

The ſhell is of a moderate thickneſs, about that of a common muſcle; it is ſomewhat tranſparent, convex like the cockle: neither of the ſhells is more ſenſibly arched than the other; that, however, which has the ſpur, is rather the moſt ſo, eſpecially in the ſuperior part.

On the ſurface of the ſhell are ſeen a number of ſlight tranſverſe depreſſions, of a ſemicircular waved form, which reach the part where the ſhell ceaſes to be circular, in order to form the angle which ſupports the ſummit.

Theſe ſtriæ are covered with a very thin and ſlightly-adhering perioſteum; in ſome ſpecimens there are from one to three ſhallow broad depreſſions, radiating inſenſibly from the centre of the ſhell, and becoming more marked as they approach the edges, where they form, with the correſponding parts of the other ſhell, thoſe ſalient and re-entering angles which have been mentioned. The perioſteum is rather more firmly fixed on the latter angles than on the former.

The ſhells are equal in the rounded part of their edge, and cloſe very exactly; however, towards the ſummit, the ſpur of one of the ſhells reaches conſiderably beyond the other ſhell, conſequently they are unequal, as in oyſters.

The ſpur, or ſummit, is formed by the folding from within of the edge of the ſhell, and the elongation of its upper part. The folded edges form an oval aperture of a moderate ſize, through which the animal extends the muſcle, by means of which it attaches itſelf to other ſubſtances. This ſhell is not, therefore, perforated, as its name of terebratula would ſeem to imply, the opening not being worked in one of the ſhells, but formed by the elongation of one ſhell, the folding in of its edges, and the approach of the other ſhell. The ſummit is not pointed, but round.

The ligament, as in the oyſter, is placed between the ſummits, and does not appear on the outſide; it adapts itſelf to the pedicle of the animal. As the ſummit takes up a conſiderable part of the ſhell, the valves are only capable of opening a very little without running the riſk of being broken. It is very firm, though ſlender, and not eaſily to be diſcovered, being fixed in a ſmall groove, which is filled up when the ſhell is ſhut by the correſponding part of the oppoſite ſhell. This ligament preſerves its texture, even for a conſiderable time after the ſhell is emptied and become dry.

Oyſters are without a hinge, the teeth which form it it in many other ſhells not exiſting in them. The anomia has been conſidered as an oyſter, becauſe its hinge or teeth have not been examined: they are not viſible indeed in the foſſile ſpecimens; but in opening them when alive, the teeth compoſing the hinge are ſufficiently viſible, being even much larger than in the greater part of bivalve ſhells. The foſſil terebratulæ are almoſt always found with their ſhells cloſed; whereas the other bivalves have uſually theirs either open or ſeparated: the reaſon of this ſeems to ariſe from the nature of the hinge, that of the anomia not allowing it to ſeparate, and the ligament, which is very tight, contributing to keep the two ſhells united. The teeth which form the hinge of the anomia approach very near to thoſe of the *ſpondyle*, deſcribed by M. Adanſon. In this laſt they are formed by two rounded projections, and in the anomia by the ſame a little elongated. It is above theſe teeth that the ligament is placed in the larger ſhell: there are between it and the teeth two cavities, one on each ſide which ſerve to receive the teeth of the other valve. The teeth of the larger ſhell have, beſides, a ſlight projection, which fits into a longitudinal furrow in the other ſhell in front of the teeth.

The ſubſtance which covers the inſide of the ſhell holds, as in oyſters, a middle place between *nacre* and the interior ſubſtance of ſhells, which are deſtitute of it. The degree of its luſtre, poliſh and thickneſs, varies with the age and circumſtances of individuals.

The colour of the teeth is always white; that of the outer ſurface of the ſhell verges more or leſs to the ochry red, eſpecially on the border. The inſide has alſo a very ſlight tint of this colour, on a varying greyiſh-white ground.

There is viſible on each ſide of the ſhell the impreſſion of two very diſtinct tendons; a circumſtance which forms a very eſſential difference between this genus and that of the oyſter: this latter having only one tendon ariſing from the middle of the body. The impreſſions of the tendon in the largeſt ſhell are oblong, ſituate near the ſummit, and hollowed; each of them has curved tranſverſe ridges, divided into two parts by a longitudinal furrow, repreſenting the wings of certain inſects. In the other valve the inſertions have a different form; their ſituation is the ſame, but they are very irregularly rounded and encompaſſed by two ſulcations, which are ſeparated from each other by an intervening ridge, and then are continued in a right line towards the opening of the ſhell as far as about two thirds of its length. That part of the ſummit of the ſhell along which the pedicle of the animal paſſes, is longitudinally ſtriated in the larger ſhell, of which the middle ſtria is the deepeſt: the longitudinal ſtriæ are divided into equal parts by a tranſverſe depreſſion. There are no ſimilar marks on the other ſhell.

Our author diſſected the animal itſelf, and found what he calls the *manteau* of the anomia, formed of a very fine membrane, lining the inſide of both ſhells, and containing the body of the animal. Its origin is of the ſame breadth as the hinge of the ſhell, whence it divides into two lobes, lining both the ſhells: it forms, therefore, only a ſingle aperture, terminating at each end of the hinge, and of the ſame breadth with the interior ſurface of the ſhell: it appears to have only one trachea, which is formed by the two lobes of the manteau.

Our naturaliſt having opened the ſhell, divided the ligament as delicately as poſſible, unfixed the hinge, and detaching from the larger ſhell the lobe of the manteau, turned over the body of the animal. This operation expoſed to view the large muſcles which adhered to the ſhell; they are ſoft, membranous, and, as it were, fleſhy on the inſide, being covered with ſmall ſanguiferous glands. From the lower part of each muſcle there proceeds a pretty ſtrong tendon, which reaches to the extremity of the manteau; they run parallel to the edge of the ſhell, and at a conſiderable diſtance from each other; and are each encloſed in a ſort of flatted ſac, of the ſhape of a ribbon, which is filled with a red viſcid matter. It appears that the place of inſertion of the muſcles, as well as the muſcles themſelves, which extend along the lobe of the manteau, furniſh real blood, which is contained in three ſmall fleſhy red glandular bodies of unequal ſize, which are viſible after having taken off the muſcles; perhaps theſe conſtitute the heart of the animal.

The muſcles which are inſerted into the other ſhell are alſo divided into ſeveral parts: ſome are ſeen extending along the correſponding lobe of the manteau; many others riſe up in a kind of tuft, which is fixed into the ſhell above: ſome again ſubdivide into ſuch minute ramifications as not to allow of tracing their courſe, even with the aſſiſtance of a microſcope; but others, more apparent, contribute to the formation of the pedicle which paſſes through the opening left between the two ſhells, is connected to each of them by ſeveral fibres, and fixes itſelf to ſome external body, principally to other bivalves. The muſcles of the anomia have therefore three attachments, namely, to the inner ſurface of each ſhell, and to ſome external body.

The form of the pedicle is cylindrical, being encloſed in a muſcular ſubſtance, which contain ſeveral fibres; it is from a line to a line and a half long, and two thirds in diameter. It adheres ſo forcibly to different ſubſtances, as that the animal, and all the muſcles which contribute to the formation of the pedicle, may more eaſily be torn through than the pedicle detached from the place of its adheſion. The glutinous ſubſtance which connects them to each other, reſiſts even the heat of boiling water. It is by means of this pedicle that the animal raiſes its ſhell ſo as to be, while in the water, in a poſition inclined to the horizon. The ſmalleſt valve is always the loweſt, being that upon which the animal reſts; the ſuperior one being the larger, and ſerving as a covering. Our author thinks the animal has the power of loco-motion.

After raiſing the lobe of the manteau he obſerved the ears. They are large, compoſed of two membranaceous laminæ on each ſide, of which the ſuperior is the narrower. Theſe laminæ are connected to each other by a thin membrane, ſo as to form only a ſingle pouch. They have on their edges long fringes, which hang looſe upon the manteau; but a very remarkable circumſtance is, that their ears are ſupported by little bones like thoſe of fiſh. The form of the ears is that of an arch; they are ſeparated from each other on their lower part, where the fringes are the longeſt; ſo that the two ears on one ſide are perfectly diſtinct from thoſe on the other ſide. The commencement of the ears is at the teeth of the hinge.

Between the ears are ſituate the ſtomach, œſophagus, and mouth; the whole forming a triangle, of which the mouth

Terebratulæ.

mouth is the base. It is placed at the side of the hinge, and consists of a large transverse opening without lips or jaw-bone. The œsophagus is very short, but is capable of elongation when the animal opens its mouth. The stomach, which is of the shape of a pointed sac, is connected by a membrane to the bones of the ear. On opening the stomach, he found a small shrimp half digested.

At the bottom of the stomach is seen the intestine, of which it is, as it were, a continuation. It is extremely short, not exceeding half a line in a shell fifteen lines across, and is composed of a very slender membrane. The excrements are discharged upon the lobes of the manteau, but they are easily thrown out by the motions of the two lobes.

The little bones of the ears, already mentioned, had not formerly been observed in any of the testaceous animals; whence the terebratulæ approach nearer to fish than the inhabitants of any other shell. In the anomiæ which are preserved in cabinets, there is found only a very small portion of these bones, whence they have obtained the improper appellation of *tongue* or *fork*, which indicate only the form of the fragments, and not their use.

The small bones of the ears are composed of several pieces, the principal of which is of an oval form; it springs from the side of the hinge, of which it appears to be a continuation; thence it extends about two-thirds of the breadth of the shell, where it is reflected, and rests against the upper part of the fork, to the branches of which it is united by a simple superposition; a kind of articulation very common among the numerous small bones that compose the heads of fish. The fork extends from the the summit a little more than one-third of the breadth of the shell: it is formed by a pivot which divides into two long and pointed branches; these are remarkably brittle, and support the extremities of the bones of the larger ears. The lamina, which composes a second set of ears, rests upon a curved bone, which on one side is attached to the inferior internal part of the bone of the larger ears, and on the other reaches to the side of the mouth of the animal, where it is united to another flat little bone, which is applied to a similar bone on the other side. These last little bones are exactly below the membrane which forms the mouth. All these bones are flat, very brittle, and surrounded with fibres and membranes. By their articulations the ears are enabled to move; they also support the body of the animal, which touches neither of the shells, but remains between them as upon tressels. The space between the branches of the bones of the ears is filled up with a transparent firm membrane; at the base of the fork is a similar one, and a perpendicular partition dividing the space occupied by the body of the animal from the rest of the shell. There are two orifices in this membrane communicating with the space between the two lobes of the manteau, and which serves as a trachea; for we have remarked, in the description of the manteau, that the two lobes are entirely separated from each other, and therefore do not form a real trachea.

From this description, it follows that the anomia ought to be separated from the genus oyster, since it has a toothed hinge, several ligaments, and an interior organization wholly different; neither ought it to be confounded with the cockle, the shells of which are both equal, and are destitute of any sensible periosteum, without reckoning other differences. It has still less analogy with the other bivalves, and therefore ought to constitute a peculiar genus; the species of which, both fossil and living, are very numerous.

See Plate XLIII. where fig. 1. is a front view of a terebratula of middle size. Fig. 2. is a view of the internal structure.—A A, laminæ of the superior ears—B B, laminæ of the inferior—C, the stomach—D, the anus—E E, the manteau—F, the œsophagus.

Terebratulæ ‖ Termina.

TERMINA, *Laguna*, or *Lake of Tides*, lies at the bottom of the Gulf of Campeachy, in the south-west part of the Gulf of Mexico. It is within Trieste and Beef Island, and Port Royal Island. The tide runs very hard in, at most of the channels between the islands; hence the name.—*Morse*.

TERNAI, the name given by Perouse to a very fine bay which he discovered on the coast of Tartary, in Lat. 45° 13′ North, and in Long. 135° 9′ East from Paris. The bottom is sandy, and diminishes gradually to six fathoms within a cable's length of the shore. The tide rises five feet; it is high water at $8^h\ 15^m$ at full and change; and the flux and reflux do not alter the direction of the current at half a league from the shore.

"Five small creeks (says La Perouse,) similar to the sides of a regular polygon, from the outline of this roadstead; these are separated from each other by hills, which are covered to the summit with trees. Never did France, in the freshest spring, offer gradations of colour of so varied and strong a green; and though we had not seen, since we began to run along the coast, either a single fire or canoe, we could not imagine that a country so near to China, and which appeared so fertile, should be entirely uninhabited. Before our boats had landed, our glasses were turned towards the shore, but we saw only bears and stags, which passed very quietly along the sea side. The same plants which grow in our climates carpeted the whole soil, but they were stronger, and of a deeper green; the greater part were in flower. Roses, red and yellow lilies, lilies of the valley, and all our meadow flowers in general, were met with at every step. Pine trees covered the tops of the mountains; oaks began only half way down, and diminished in strength and size in proportion as they came nearer the sea; the banks of the rivers and rivulets were bordered with willow, birch, and maple trees, and on the skirts of the forests we saw apple and medlar trees in flower, with clumps of hazle nut trees, the fruit of which already made its appearance. Our surprise was redoubled, when we reflected on the population which overburdens the extensive empire of China, so that the laws do not punish fathers barbarous enough to drown and destroy their children, and that this people, whose polity is so highly boasted of, dares not extend itself beyond its wall, to draw its subsistence from a land, the vegetation of which it would be necessary rather to check than to encourage. At every step after we had landed, we perceived traces of men by the destruction they had made; several trees, cut with sharp edged instruments; the remains of ravages by fire were to be seen in several places, and we observed some sheds, which had been erected by hunters in a corner of the woods. We also found some small baskets, made of the bark of birch trees, sewed with thread, and similar to those of the Canadian Indians;

rackets

rackets for walking on the ſnow; in a word, every thing induced us to think that the Tartars approach the borders of the ſea in the ſeaſon for hunting and fiſhing; that they aſſemble in colonies at that period along the rivers; and that the bulk of the nation live in the interior of the country on a ſoil perhaps better calculated for the multiplication of their immenſe flocks and herds."

Our navigators caught in the bay vaſt quantities of fine fiſh, ſuch as cod, harp-fiſh, trout, ſalmon, herrings, and plaice; but though game was plenty on ſhore, they had no ſucceſs in hunting. The meadows, ſo delightful to the ſight, could ſcarce be croſſed; the thick graſs was three or four feet high, ſo that they found themſelves in a manner buried in it, and they were under the perpetual dread of being bitten by ſerpents, of which they ſaw a great number on the banks of the rivulets. They found, however, immenſe quantities of ſmall onions, ſorrel, and celery; which, together with the freſh fiſh, ſerved as antidotes againſt the ſcurvy.

TERRA *de Latraton*, that is, the *Ploughman* or *Labourer's Land*, the name given by the Spaniards to Labrador or New-Britain, inhabited by the Eſquimaux.—*Morse.*

TERRA *del Fuego Iſland*, or *Land of Fire*, at the ſouth extremity of S. America, is ſeparated from the main on the N. by the Straits of Magellan, and contains about 42,000 ſquare miles. This is the largeſt of the iſlands ſouth of the Straits, and they receive this name on account of the vaſt fires and ſmoke which the firſt diſcoverers of them perceived. The iſland of Staten Land lies on the eaſt. They are all barren and mountainous; but there have been found ſeveral ſorts of trees and plants, and a variety of birds on the lower grounds and iſlands that are ſheltered by the hills. Here are found Winter's bark, and a ſpecies of arbutus which has a very well taſted red fruit of the ſize of ſmall cherries. Plenty of celery is found in ſome places, and the rocks are covered with very fine muſcles. A ſpecies of duck as large as a gooſe, and called the loggerhead duck at the Falkland Iſlands, is here met with, which beats the water with its wings and feet, and runs along the ſea with inconceivable velocity; and there are alſo geeſe and falcons.—*ib.*

TERRA FIRMA, or *Caſtile del Oro*, the moſt northern province of S. America, 1,400 miles in length, and 700 in breadth; ſituated between the equator and 12 N. lat. and between 60 and 82 W. long. bounded N. by the N. Atlantic Ocean, here called the North Sea, E. by the ſame ocean and Surinam, S. by Amazonia and Peru, and W. by the N. Pacific Ocean. It is called Terra Firma from being the firſt part of the continent diſcovered by the Spaniards, and is divided into Terra Firma Proper, or Darien, Carthagena, St Martha, Venezuela, Comana, Paria, New Granada, and Popayan. The chief towns are Porto Bello, Panama, Carthagena, and Popayan. The principal bays of this province in the Pacific Ocean, are thoſe of Panama and St Michael, in the North Sea, Porto Bello, Sino, Guiara, &c. The chief rivers are the Darien, Chagre, Santa Maria, Conception, and Oronoko. The climate here, eſpecially in the northern parts, is extremely hot and ſultry during the whole year. From the month of May, to the end of November, the ſeaſon called winter by the inhabitants, is almoſt a continual ſucceſſion of thunder, rain and tempeſts, the clouds precipitating the rain with ſuch impetuoſity, that the low lands exhibit the appearance of an ocean. Great part of the country is conſequently flooded; and this, together with the exceſſive heat, ſo impregnates the earth with vapours, that in many provinces, particularly about Popayan and Porto Bello, the air is extremely unwholeſome. The ſoil of this country is very different, the inland parts being very rich and fertile, and the coaſts ſandy and barren. It is impoſſible to view without admiration, the perpetual verdure of the woods, the luxuriancy of the plains, and the towering height of the mountains. This country produces corn, ſugar, tobacco, &c. and fruits of all kinds. This part of S. America was diſcovered by Columbus in his third voyage to America. It was ſubdued and ſettled by the Spaniards about the year 1514, after deſtroying, with great inhumanity, ſeveral millions of the natives. —*ib.*

TERRA FIRMA *Proper*, or *Darien*, a ſubdiviſion of Terra Firma. Chief towns, Porto Bello, and Panama.—*ib.*

TERRA *Nueva*, near Hudſon's Straits, is in lat. 62 4 N. and long. 67 W. high water, at full and change, a little before 10 o'clock.—*ib.*

TERRE PLEIN, or TERRE-PLAIN, in fortification, the top, platform, or horizontal ſurface of the rampart, upon which the cannon are placed, and where the defenders perform their office. It is ſo called becauſe it lies level, having only a little ſlope outwardly to counteract the recoil of the cannon. Its breadth is from 24 to 30 feet; being terminated by the parapet on the outer ſide, and inwardly by the inner talus.

TERRELLA, or little earth, is a magnet turned of a ſpherical figure, and placed ſo as that its poles, equator, &c. do exactly correſpond with thoſe of the world. It was ſo firſt called by Gilbert, as being a juſt repreſentation of the great magnetic globe we inhabit. Such a terrella, it was ſuppoſed, if nicely poiſed, and hung in a meridian like a globe, would be turned round like the earth in 24 hours by the magnetic particles pervading it; but experience has ſhewn that this is a miſtake.

TERRITORY *North-Weſt of the Ohio*, or *North-Weſtern Territory*, a large part of the United States, is ſituated between 37 and 50 N. lat. and between 81 8 and 98 8 W. long. Its greateſt length is about 900 miles, and its breadth 700. This extenſive tract of country is bounded north by part of the northern boundary line of the United States; eaſt by the lakes and Pennſylvania; ſouth by the Ohio river; weſt by the Miſſiſſippi. Mr Hutchins, the late geographer of the United States, eſtimates that this tract contains 263,040,000 acres, of which 43,040,000 are water; this deducted, there will remain 220,000,000 of acres, belonging to the Federal Government, to be ſold for the diſcharge of the national debt; except a narrow ſtrip of land bordering on the ſouth of Lake Erie, and ſtretching 120 miles weſt of the weſtern limit of Pennſylvania, which belongs to Connecticut. But a ſmall portion of theſe lands is yet purchaſed of the natives, and to be diſpoſed of by Congreſs. Beginning on the meridian line, which forms the weſtern boundary of Pennſylvania, ſeven ranges of townſhips have been ſurveyed and laid off by order of Congreſs. As a north and

Territory. and south line strikes the Ohio in an oblique direction, the termination of the 7th range falls upon that river, 9 miles above the Muskingum, which is the first large river that falls into the Ohio. It forms this junction 172 miles below Fort Pitt, including the windings of the Ohio, though, in a direct line, it is but 90 miles. That part of this territory in which the Indian title is extinguished, and which is settling under the government of the United States, is divided into five counties as follows:

Counties.	When erected.
Washington, - -	1788 July 26th.
Hamilton, - - -	1790 Jan. 2d.
St Clair, - - -	1790 April 27th.
Knox, - - -	1790 June 20th.
Wayne, - - -	1796.

These counties have been organized with the proper civil and military officers. The county of St Clair is divided into three districts, viz. the district of Cahokia, the district of Prairie-du-rochers, and the district of Kaskaskias. Courts of general quarter sessions of the peace, county courts of common pleas, and courts of probate, to be held in each of these districts, as if each was a distinct county; the officers of the county to act by deputy, except in the district where they reside. The principal rivers in this territory are Muskingum, Hockhocking, Sciota, Great and Little Miami, Blue and Wabash, which empty into the Ohio; Au Vase, Illinois, Ouisconsing, and Chippeway, which pay tribute to the Mississippi, besides a number of smaller ones. St Lewis, Kennotnic, St Joseph's, Barbue, Grand, Miami of the Lakes, Sandusky, Cayahoga, and many others which pass to the lakes. Between the Kaskaskias and Illinois rivers, which are 84 miles apart, is an extensive tract of level, rich land, which terminates in a high ridge, about 15 miles before you reach the Illinois river. In this delightful vale are a number of French villages, which, together with those of St Genevieve, and St Louis, on the western side of the Mississippi, contained, in 1771, 1273 fencible men. The number of souls in this large tract of country, has not been ascertained. From the best data the author has received, the population may be estimated, five years ago, as follows:

Indians, (suppose) - -	65,000	1792.
Ohio Company purchase, -	2,500	do.
Col. Symmes' settlements, -	2,000	do.
Galliopolis, (French settlements) opposite the Kanhaway river,	1,000	do.
Vincennes and its vicinity, on the Wabash,	1,500	do.
Kaskaskias and Cahokia, -	680	1790.
At Grand Ruisseau, village of St Philip, and Prairie-du-rochers,	240	do.
Total	72,820	

In 1790, there were in the town of Vincennes, about 40 American families and 31 slaves, and on the Mississippi, 40 American families and 73 slaves, all included in the above estimate. On the Spanish or western side of the Mississippi, there were, in 1790, about 1800 souls, principally at Genevieve, and St Louis. The lands on the various rivers which water this territory, are interspersed with all the variety of soil which conduces to pleasantness of situation, and lays the foundation for the wealth of an agricultural and manufacturing people. Large level bottoms, or natural meadows, from 20 to 50 miles in circuit, are found bordering the rivers, and variegating the country in the interior parts. These afford as rich a soil as can be imagined, and may be reduced to proper cultivation with very little labour. The prevailing growth of timber, and the more useful trees, are maple or sugar-tree, sycamore, black and white mulberry, black and white walnut, butternut, chesnut; white, black, Spanish, and chesnut oaks, hickory, cherry, buckwood or horse chesnut, honey-locust, elm, cucumber tree, lynn tree, gum tree, iron wood, ash, aspin, sassafras, crab-apple tree, paupaw or custard apple, a variety of plum trees, nine bark spice, and leather wood bushes. White and black oak, and chesnut, with most of the above-mentioned timbers, grow large and plenty upon the high grounds. Both the high and low lands produce great quantities of natural grapes of various kinds, of which the settlers universally make a sufficiency for their own consumption, of rich red wine. It is asserted in the old settlement of St Vincent, where they have had opportunity to try it, that age will render this wine preferable to most of the European wines. Cotton is said to be the natural production of this country, and to grow in great perfection. The sugar maple is the most valuable tree, for an inland country. Any number of inhabitants may be forever supplied with a sufficiency of sugar, by preserving a few trees for the use of each family. A tree will yield about ten pounds of sugar a year, and the labour is very trifling. Springs of excellent water abound in this territory; and small and large streams, for mills and other purposes, are actually interspersed, as if by art, that there be no deficiency in any of the conveniencies of life. Very little waste land is to be found in any part of this tract of country. There are no swamps but such as may be readily drained, and made into arable and meadow land; and though the hills are frequent, they are gentle, and swelling no where high or incapable of tillage. They are of a deep rich soil, covered with a heavy growth of timber, and well adapted to the production of wheat, rye, indigo, tobacco, &c. The communication between this country and the sea, will be principally in the 4 following directions: 1. The route through the Scioto and Muskingum to Lake Erie, and so to the river Hudson. 2. The passage up the Ohio and Monongahela to the portage above mentioned, which leads to the navigable waters of the Patowmack. This portage is 30 miles, and will probably be rendered much less by the execution of the plans now on foot for opening the navigation of those waters. 3. The Great Kanhaway, which falls into the Ohio from the Virginia shore, between the Hockhocking and the Scioto, opens an extensive navigation from the south-east, and leaves but 18 miles portage from the navigable waters of James' river, in Virginia. This communication, for the country between Muskingum and Scioto, will probably be more used than any other for the exportation of manufactures, and other light and valuable articles, and especially, for the importation of foreign commodities, which may be brought from the Chesapeak to the Ohio much cheaper than they are now carried from Philadelphia to Carlisle, and the other thick settled back counties of Pennsyl-

Pennfylvania (A). 4. But the current down the Ohio and Miffiffippi, for heavy articles that fuit the Florida and Weft-India markets, fuch as corn, flour, beef, lumber, &c. will be more frequently loaded than any ftreams on earth. The diftance from the Scioto to the Miffiffippi, is 800 miles; from thence to the fea, is 900. This whole courfe is eafily run in 15 days; and the paffage up thofe rivers is not fo difficult as has ufually been reprefented. It is found, by late experiments, that fails are ufed to great advantage againft the current of the Ohio; and it is worthy of obfervation, that in all probability fteam boats will be found to do infinite fervice in all our extenfive river navigation. No country is better ftocked with wild game of every kind. The rivers are well ftored with fifh of various kinds, and many of them are of an excellent quality. They are generally large, though of different fizes; the catfifh, which is the largeft, and of a delicious flavour, weighs from 6 to 80 pounds. The number of old forts, found in this weftern country, are the admiration of the curious, and a matter of much fpeculation. They are moftly of an oblong form, fituated on ftrong, well chofen ground, and contiguous to water. When, by whom, and for what purpofe, thefe were thrown up, is uncertain. They are undoubtedly very ancient, as there is not the leaft vifible difference in the age or fize of the timber growing on or within thefe forts, and that which grows without; and the oldeft natives have loft all tradition refpecting them. The pofts eftablifhed for the protection of the frontiers, and their fituation, may be feen on the map. By an ordinance of Congrefs, paffed on the 13th of July, 1787, this country, for the purpofes of temporary government, was erected into one diftrict, fubject, however, to a divifion, when circumftances fhall make it expedient. The ordinance of Congrefs, of July 13th, 1787, article 5th, provides that there fhall be formed in this territory, not lefs than three, nor more than five States; and the boundaries of the States fhall become fixed and eftablifhed as follows, viz. the weftern State in the faid territory fhall be bounded on the Miffiffippi, the Ohio and Wabafh rivers; a direct line drawn from the Wabafh and Poft Vincents due north to the territorial line between the United States and Canada, and by the faid territorial line to the Lake of the Woods and Miffiffippi. The middle State fhall be bounded by the faid direct line, the Wabafh from Poft Vincents to the Ohio; by the Ohio by a direct line drawn due north from the mouth of the Great Miami to the faid territorial line, and by the faid territorial line. The eaftern State fhall be bounded by the laft mentioned direct line, the Ohio, Pennfylvania, and the faid territorial line: Provided however, and it is further underftood and declared, that the boundaries of thefe 3 States fhall be fubject fo far to be altered, that if Congrefs hereafter fhall find it expedient, they fhall have authority to form 1 or 2 States, in that part of the faid territory which lies N. of an E. and W. line drawn through the foutherly bend or extreme of Lake Michigan; and when any of the faid States fhall have 60,000 free inhabitants therein, fuch State fhall be admitted by its delegates into the Congrefs of the United States, on an equal footing with the original States in all refpects whatever; and fhall be at liberty to form a permanent conftitution and State government; provided the conftitution and government fo to be formed fhall be republican, and in conformity to the principles contained in thefe articles, and fo far as it can be confiftent with the general intereft of the confederacy, fuch admiffion fhall be allowed at an earlier period, and when there may be a lefs number of free inhabitants in the State, than 60,000. The fettlement of this country has been checked, for feveral years paft, by the unhappy Indian war, an amicable termination of which took place on the 3d of Auguft, 1795, when a treaty was formed at Grenville, between Major Gen. Anthony Wayne, on the part of the United States, and the Chiefs of the following tribes of Indians, viz. Wyandots, Delawares, Shawanoes, Ottawas, Chippewas, Putawatimes, Miamis, Eel river, Weeas, Kickapoos, Pian-Kafhaws and Kafkafkias. By the third article of this treaty, the Indians cede to the United States, for a valuable confideration, all lands lying eaftward and fouthward of a line "beginning at the mouth of Cayahoga river, and running thence up the fame to the portage between that and the Tufcarawas branch of the Mufkingum; thence down that branch to the croffing place above Fort Lawrence; thence wefterly to a fork of that branch of the Great Miami river, running into the Ohio, where commences the portage between the Miami of the Ohio, and St Mary's river, which is a branch of the Miami of the lake; thence a wefterly courfe to Fort Recovery, which ftands on a branch of the Wabafh, then fouth-wefterly in a direct line to the Ohio, fo as to interfect that river oppofite the mouth of Kentucky or Catawa river." Sixteen tracts of land of 6 and 12 miles fquare, interfperfed at convenient diftances in the Indian country, were, by the fame treaty, ceded to the United States, for the convenience of keeping up a friendly and beneficial intercourfe between the parties. The United States, on their part, "relinquifh their claims to all other Indians lands northward of the river Ohio, eaftward of the Miffiffippi, and weftward and fouthward of the Great Lakes and the waters uniting them, according to the boundary line agreed on by the United States and the king of Great Britain, in the treaty of peace made between them in the year 1783. But from this relinquifhment, by the United States, the following tracts of land are explicitly excepted. 1ft. The tract of 150,000 acres near the rapids of the Ohio river, which has been affigned to Gen. Clark, for the ufe of himfelf and his warriors. 2d. The poft of St Vincents on the river Wabafh, and the lands adjacent; of which the Indian title has been extinguifhed. 3d. The land at all other places in poffeffion of the French people and other white fettlers among them, of which the Indian title has been extinguifhed, as mentioned in the third article; and 4th. The poft of Fort Maffac, towards the mouth of the Ohio. To which feveral parcels of land fo excepted, the faid tribes relinquifh all the title and claim which they or any of them may have." Goods to the value of 20,000 dolls. were delivered

(A) A gentleman of much obfervation, and a great traveller in this country, is of opinion that this communication, or route, is chimerical.

delivered the Indians at the time this treaty was made; and goods to the amount of 9,500 dollars, at firft coft in the United States, are to be delivered annually to the Indians at fome convenient place northward of the Ohio. A trade has been opened, fince this treaty, by a law of Congrefs, with the forementioned tribes of Indians, on a liberal footing, which promifes to give permanency to this treaty, and fecurity to the frontier inhabitants.—*Morse.*

TESTIGOS, iflands near the coaft of New Andalufia, in Terra Firma, on the fouth coaft of the Caribbean Sea, in the Weft-Indies. Several fmall iflands at the eaft end of the ifland of Margarita lie between that ifland, and thofe called Teftigos. N. lat. 11 6, W. long. 61 48.—*ib.*

TETEROA *Harbour*, on the W. fide of the ifland of Ulietea, one of the Society Iflands. S. lat. 16 51, W. long. 151 27.—*ib.*

TETHUROA, an ifland in the S. Pacific Ocean, about 24 miles from Point Venus in the ifland of Otaheite. S. lat. 17 4, W. long. 149 30.—*ib.*

TETRAEDRON, or TETRAHEDRON, in geometry, is one of the five Platonic or regular bodies or folids, comprehended under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

TETRAGON, in geometry, a quadrangle, or a figure having four angles. Such as a fquare, a parallelogram, a rhombus, and a trapezium. It fometimes alfo means peculiarly a fquare.

TETRAGON, in aftrology, denotes an afpect of two planets with regard to the earth, when they are diftant from each other a fourth part of a circle, or 90 degrees. The tetragon is expreffed by the character □, and is otherwife called a fquare or quartile afpect.

TETZEUCO, a brackifh lake in Mexico.—*Morse.*

TEUSHANUSHSONG-GOGHTA, an Indian village on the northern bank of Alleghany river, in Pennfylvania, 5 miles north of the fouth line of the ftate, and 14 E. S. E. of Chatoughque Lake.—*ib.*

TEWKSBURY, called by the Indians, *Wamefit* or *Pawtuket*, a townfhip of Maffachufetts, Middlefex county, on Concord river, near its junction with Merrimack river, 24 miles northerly of Bofton. It was incorporated in 1734, and contains 958 inhabitants.—*ib.*

TEWKSBURY, a townfhip of New Jerfey, Hunterdon county. The townfhip of Lebanon, Readington, and Tewkfbury contain 4,370 inhabitants, including 268 flaves.—*ib.*

THAMES *River*, in Connecticut, is formed by the union of Shetucket and Little, or Norwich rivers, at Norwich Landing, to which place it is navigable for veffels of confiderable burden; and thus far the tide flows. From this place the Thames purfues a foutherly courfe 14 miles, paffing by New-London on its weft bank, and empties into Long-Ifland Sound; forming the fine harbour of New-London.—*ib.*

THATCHER's *Ifland*, lies about a mile eaft of the fouth-eaft point of Cape Ann, on the coaft of Maffachufetts, and forms the northern limit of Maffachufetts Bay; and has two light-houfes. Cape Ann light-houfe lies in lat. 43 36 north, and long. 70 47 weft. —*ib.*

THEAKIKI, the eaftern head water of Illinois river, rifes about 8 miles S. of Fort St Jofeph. After running through rich and level lands, about 112 miles, it receives Plein river in lat. 41 48 N. and from thence the confluent ftream affumes the name of Illinois. In fome maps it is called *Huakiki*.—*ib.*

THEBES, in Egypt. Having in the *Encyclopædia* given Mr Bruce's account of this ancient city, which reprefents it as having been a paltry place, fo contrary to the defcription of Homer, juftice to the father of poetry requires that we here notice what has been faid of it by a fubfequent traveller, who remained three days among its ruins. According to Mr Browne, "the maffy and magnificent forms of the ruins that remain of ancient Thebes, the capital of Egypt, the city of Jove, the city with 100 gates, muft infpire every intelligent fpectator with awe and admiration. Diffufed on both fides of the Nile, their extent confirms the claffical obfervations, and Homer's animated defcription rufhes into the memory:

'Egyptian Thebes, in whofe palaces vaft wealth is ftored; from each of whofe hundred gates iffue two hundred warriors, with their horfes and chariots.'

"These venerable ruins, probably the moft ancient in the world, extend for about three leagues in length along the Nile. Eaft and weft they reach to the mountains, a breadth of about two leagues and a half. The river is here about three hundred yards broad. The circumference of the ancient city muft therefore have been about twenty-feven miles.

"In failing up the Nile, the firft village you come to within the precincts is Kourna, on the weft, where there are few houfes, the people living moftly in the caverns. Next is Abuhadjadj, a village, and Karnac, a fmall diftrict, both on the eaft. Far the largeft portion of the city ftood on the eaftern fide of the river. On the fouth-weft Medinet-Abu marks the extremity of the ruins; for Arment, which is about two leagues to the fouth, cannot be confidered as a part.

"In defcribing the ruins, we fhall begin with the moft confiderable, which are on the eaft of the Nile. The chief is the Great Temple, an oblong fquare building of vaft extent, with a double colonnade, one at each extremity. The maffy columns and walls are covered with hieroglyphics; a labour truly ftupendous. 1. The Great Temple ftands in the diftrict called *Karnac*. 2. Next in importance is the temple at *Abuhadjadj*. 3. Numerous ruins, avenues marked with remains of fphinxes, &c. On the weft fide of the Nile appear, 1. Two coloffal figures, apparently of a man and woman, formed of a calcareous ftone like the reft of the ruins. 2. Remains of a large temple, with caverns excavated in the rock. 3. The magnificent edifice ftyled the *palace of Memnon*. Some of the columns are about forty feet high, and about nine and a half in diameter. The columns and walls are covered with hieroglyphics. This ftands at *Kourna*. 4. Behind the palace is the paffage ftyled *Bibân-el-Meluk*, leading up the mountain. At the extremity of this paffage, in the fides of the rock, are the celebrated caverns known as the fepulchres of the ancient kings."

Though Mr Browne agrees with Pococke and Bruce, that the paffage in Homer refers not to the gates of the city, he is yet of opinion, contrary to them, that Thebes had been a walled town. He fays, indeed, that fome faint remains of its furrounding wall are vifible at this day; and he thinks that he difcovered the ruins of three

three of its gates, though he does not affirm this with absolute confidence.

THEODOSIUS, a celebrated mathematician, flourished in the times of Cicero and Pompey; but the time and place of his death are unknown. This Theodosius, the Tripolite, as mentioned by Suidas, is probably the same with Theodosius the philosopher of Bythinia, who, Strabo says, excelled in the mathematical sciences, as also his sons; for the same person might have travelled from the one of those places to the other, and spent part of his life in each of them; like as Hipparchus was called by Strabo the Bythinian, but by Ptolemy and others the Rhodian.

Theodosius chiefly cultivated that part of geometry which relates to the doctrine of the sphere, concerning which he published three books. The first of these contains 22 propositions; the second, 23; and the third, 14; all demonstrated in the pure geometrical manner of the ancients. Ptolemy made great use of these propositions, as well as all succeeding writers. These books were translated by the Arabians, out of the original Greek, into their own language. From the Arabic the work was again translated into Latin, and printed at Venice. But the Arabic version being very defective, a more complete edition was published, in Greek and Latin, at Paris 1558, by John Pena, Regius Professor of astronomy. And Vitello acquired reputation by translating Theodosius into Latin. This author's works were also commented on and illustrated by Clavius, Heleganius, and Guarinus, and lastly by De Chales, in his Cursus Mathematicus. But that edition of Theodosius's Spherics, which is now most in use, was translated and published by our countryman the learned Dr Barrow, in the year 1675, illustrated and demonstrated in a new and concise method. By this author's account, Theodosius appears, not only to be a great master in this more difficult part of geometry, but the first considerable author of antiquity who has written on that subject.

Theodosius, too, wrote concerning the Celestial Houses; also of Days and Nights; copies of which, in Greek, were in the King's library at Paris. Of which there was a Latin edition, published by Peter Dasypody, in the year 1572.

THEON, of Alexandria, a celebrated Greek philosopher and mathematician, who flourished in the 4th century, about the year 380, in the time of Theodosius the Great; but the time and manner of his death are unknown. His genius and disposition for the study of philosophy were very early improved by close application to all its branches; so that he acquired such a proficiency in the sciences as to render his name venerable in history, and to procure him the honour of being president of the famous Alexandrian school. One of his pupils was the admirable Hypatia, his daughter, who succeeded him in the presidency of the school; a trust which, like himself, she discharged with the greatest honour and usefulness. See her life, *Encycl.*

The study of Nature led Theon to many just conceptions concerning God, and to many useful reflections in the science of moral philosophy. Hence, it is said, he wrote with great accuracy on Divine Providence. And he seems to have made it his standing rule, to judge the truth of certain principles, or sentiments, from their natural or necessary tendency. Thus, he says, that a

full persuasion that the Deity sees every thing we do, is the strongest incentive to virtue; for he insists, that the most profligate have power to refrain their hands, and hold their tongues, when they think they are observed, or overheard, by some person whom they fear or respect. With how much more reason then, says he, should the apprehension and belief, that God sees all things, restrain men from sin, and constantly excite them to their duty? He also represents this belief concerning the Deity as productive of the greatest pleasure imaginable, especially to the virtuous, who might depend with greater confidence on the favour and protection of Providence. For this reason, he recommends nothing so much as meditation on the presence of God: and he recommended it to the civil magistrate as a restraint on such as were profane and wicked, to have the following inscription written, in large characters, at the corner of every street—God sees thee, O Sinner.

Theon wrote notes and commentaries on some of the ancient mathematicians. He composed also a book, intitled *Progymnosmata*, a rhetorical work, written with great judgment and elegance; in which he criticised on the writings of some illustrious orators and historians; pointing out, with great propriety and judgment, their beauties and imperfections; and laying down proper rules for propriety of style. He recommends conciseness of expression, and perspicuity, as the principal ornaments. This book was printed at Basle in the year 1541; but the best edition is that of Leyden, in 1626, in 8vo.

THEOPHILANTHROPISTS, a sect of deists, who, in September 1796, published at Paris a sort of catechism or directory for social worship, under the title of *Manuel des Theanthrophiles*. This religious breviary found favour: the congregation became numerous; and in the second edition of their manual they assumed the less harsh denomination of *Theophilanthropes*, *i. e.* lovers of God and man. A book of hymns, a liturgy for every decade of the French year, and an homiletical selection of moral lessons, are announced, or published, by their unknown synod. Thus they possess a system of pious services adapted to all occasions, which some one of the individuals who attend reads aloud; for they object to the employment of a regular lecturer, in consequence of their hostility to priests.—This novel sect was countenanced by Lareveillere Lepaux, one of the Directory, and, soon after its formation, opened temples of its own in Dijon, and in other provincial towns. They had declamations, in the spirit of sermons, which abounded with such phrases as *l'eternal geometre*, and the like, and which have long since been familiar to those who frequent the lodges of free masonry. Whether the sect now exists, or fell at the last revolution which annihilated the directory, we have not learned; but a translation of its *Manuel* into English, for the use, we suppose, of our Jacobins, was made so early as the year 1797. From this contemptible performance, we learn that the creed of the Theophilanthropists is comprised in the four following propositions:

The Theophilanthropists believe in the existence of God, and the immortality of the soul.

The spectacle of the universe attests the existence of the First Being.

The faculty which we possess of thinking, assures us, that

that we have, within ourselves, a principle which is superior to matter, and which survives the dissolution of the body.

The existence of God, and the immortality of the soul, do not need long demonstrations; they are sentimental truths, which every one may find written in his heart, if he consult it with sincerity.

Thus a sort of religious instinct is set up as the sole foundation of piety, which every one has as much right to disavow as another to assert; and the obligations of which, therefore, can in no way be shewn to be incumbent on those to whom this novel illumination is not vouchsafed. Society, under such a system, gains no means of influencing the conduct of refractory members.

The morality of the Theophilanthropists is founded on one single precept: *Worship God, cherish your kind, render yourselves useful to your country!*

Among the duties comprehended under the denomination of cherishing our kind, we find that of *not lending for usury:* the others are chiefly extracted from the gospels, and do not interfere with the province of the civil magistrate. The question of monogamy is not discussed.

Among the duties to our country are placed those of fighting in its defence, and of paying the taxes. It was certainly prudent in the statesman to slide these duties into the catalogue of his established maxims of morality; and he ran thereby little risk of provoking heretical animadversions on his creed in France.

The following inscriptions are ordered to be placed above the altars in the several temples or synagogues of the Theophilanthropists; but for what reason altars are admitted into such synagogues we are not informed:

First inscription, "We believe in the Existence of God, in the immortality of the soul."

Second inscription, "Worship God, cherish your kind, render yourselves useful to the country."

Third inscription, "Good is every thing which tends to the preservation or the perfection of man.—Evil is every thing which tends to destroy or to deteriorate him."

Fourth inscription, "Children, honour your fathers and mothers. Obey them with affection. Comfort their old age.—Fathers and mothers, instruct your children.

Fifth inscription, "Wives, regard in your husbands the chiefs of your houses.—Husbands, love your wives, and render yourselves reciprocally happy."

This pentalogue is chiefly objectionable on account of the vague drift of the fifth commandment: the whole has too general a turn for obvious practical application. The introduction of ceremonies of sculpture, of painting, and of engraving, is forbidden. If poetry and music may concur to render the worship impressive, why not the other fine arts? The fine arts have never illustrated a country which excluded them from the public temples. Are they to be extinguished in France by Theophilanthropic iconoclasts?

At p. 28. of the Manuel, this surprising maxim occurs: *Avoid innovations!* A sect fifteen months old grown as testy as the church of Rome! They acknowledge, that perhaps better inscriptions may be found: yet they forbid the exchange? They prefer *mumpsimus* to the *sumpsimus* of genuine Christianity!

THEOPHILUS, a writer and bishop of the primitive church, was educated a Heathen, and afterwards converted to Christianity. Some have imagined that he is the person to whom St Luke dedicates the Acts of the Apostles; but they are grossly mistaken; for this Theophilus was so far from being contemporary with St Luke and the apostles, that he was not ordained bishop of Antioch till *anno* 170; and he governed this church twelve or thirteen years. He was a vigorous opposer of certain heretics of his time, and composed a great number of works; all of which are lost, except three books to Autolycus, a learned Heathen of his acquaintance, who had undertaken to vindicate his own religion against that of the Christians. The first book is properly a discourse between him and Autolycus, in answer to what this Heathen had said against Christianity. The second is to convince him of the falsehood of his own, and the truth of the Christian religion. In the third, after having proved that the writings of the Heathens are full of absurdities and contradictions, he vindicates the doctrine and the lives of the Christians from those false and scandalous imputations which were then brought against them. Lastly, at the end of his work, he adds an historical chronology from the beginning of the world to his own time, to prove that the history of Moses is at once the most ancient and the truest; and it appears from this little epitome, how well this author was acquainted with profane history. These three books are filled with a great variety of curious disquisitions concerning the opinions of the poets and philosophers, and there are but few things in them relating immediately to the doctrines of the Christian religion. Not that Theophilus was ignorant of these doctrines, but, having composed his works for the conversion of a Pagan, he insisted rather on the external evidence or proofs from without, as better adapted, in his opinion, to the purpose. His style is elegant, and the turn of his thoughts very agreeable; and this little specimen is sufficient to shew that he was indeed a very eloquent man.

Biog. Dict.

The piece is entitled, in the Greek manuscripts, "The books of Theophilus to Autolycus, concerning the Faith of the Christians, against the malicious detractors of their religion." They were published, with a Latin version, by Conradus Gesner, at Zurich, in 1546. They were afterwards subjoined to Justin Martyr's works, printed at Paris in 1615 and 1636; then published at Oxford, 1684, in 12mo. under the inspection of Dr Fell; and, lastly, by Jo. Christ. Wolfius, at Hamburgh, 1723, in 8vo.

It is remarkable, that this patriarch of Antioch was the first who applied the term *Trinity* to express the Three Persons in the Godhead.

THERAPEUTÆ, so called from the extraordinary purity of their religious worship, were a Jewish sect, who, with a kind of religious phrenzy, placed their whole felicity in the contemplation of the Divine nature. Detaching themselves wholly from secular affairs, they transferred their property to their relations or friends, and withdrew into solitary places, where they devoted themselves to a holy life. The principal society of this kind was formed near Alexandria, where they lived, not far from each other, in separate cottages, each of which had its own sacred apartment, to which the inhabitant retired for the purposes of devotion. After their morning prayers, they spent the day in

Therapeutæ. ‖ Thermometric.

in ſtudying the law and the prophets, endeavouring by the help of the commentaries of their anceſtors, to diſcover ſome allegorical meaning in every part. Beſides this, they entertained themſelves with compoſing ſacred hymns in various kinds of metre. Six days of the week were, in this manner, paſſed in ſolitude. On the ſeventh day they met, clothed in a decent habit, in a public aſſembly; where, taking their places according to their age, they ſat, with the right hand between the breaſt and the chin, and the left at the ſide. Then ſome one of the elders, ſtepping forth into the middle of the aſſembly, diſcourſed, with a grave countenance and a calm tone of voice, on the doctrines of the ſect; the audience in the mean time, remaining in perfect ſilence, and occaſionally expreſſing their attention and approbation by a nod. The chapel where they met was divided into two apartments; one for the men, the other for the women. So ſtrict a regard was paid to ſilence in theſe aſſemblies, that no one was permitted to whiſper, or even to breathe aloud; but when the diſcourſe was finiſhed, if the queſtion which had been propoſed for ſolution had been treated to the ſatisfaction of the audience, they expreſſed their approbation by a murmur of applauſe. Then the ſpeaker, riſing, ſung a hymn of praiſe to God, in the laſt verſe of which the whole aſſembly joined. On great feſtivals, the meeting was cloſed with a vigil, in which ſacred muſic was performed, accompanied with ſolemn dancing; and theſe vigils were continued till morning, when the aſſembly, after a morning prayer, in which their faces were directed towards the riſing ſun, was broken up. So abſtemious were theſe aſcetics, that they commonly ate nothing before the ſetting ſun, and often faſted two or three days. They abſtained from wine, and their ordinary food was bread and herbs.

Much diſpute has ariſen among the learned concerning this ſect. Some have imagined them to have been Judaizing Gentiles, but Philo ſuppoſes them to be Jews, by ſpeaking of them as a branch of the ſect of Eſſenes, and expreſsly claſſes them among the followers of Moſes. Others have maintained, that the Therapeutæ were an Alexandrian ſect of Jewiſh converts to the Chriſtian faith, who devoted themſelves to a monaſtic life. But this is impoſſible; for Philo, who wrote before Chriſtianity appeared in Egypt, ſpeaks of this as an eſtabliſhed ſect. From comparing Philo's account of this ſect with the ſtate of philoſophy in the country where it flouriſhed, we conclude, that the Therapeutæ were a body of Jewiſh fanatics, who ſuffered themſelves to be drawn aſide from the ſimplicity of their ancient religion by the example of the Egyptians and Pythagoreans. How long this ſect continued is uncertain: But it is not improbable that, after the appearance of Chriſtianity in Egypt, it ſoon became extinct.

THERMOMETRIC SPECTRUM, is a name given to the ſpace in which a thermometer may be placed, ſo that it ſhall be affected by the ſun's rays refracted by a priſm. It is, in part, the ſame with the PRISMATIC SPECTRUM, which exhibits the different colours produced by the ſolar light.

The philoſophical inſtrument now called a *thermometer*, was firſt named THERMOSCOPE; and was prized by the naturaliſt, becauſe it gave him indications of the preſence and agency of fire in many caſes where our ſenſation of warmth or heat was unable to diſcover it. It was not long before it was obſerved that it alſo affords us meaſures of the changes which take place either in the quantity or the activity of the cauſe of heat, and of many other important phenomena uſually accompanied by heat. They were then called *thermometers*. But in both of theſe offices, it is ſtill a doubt whether it indicates and meaſures any real ſubſtance, a being *ſui generis*, to which we may give the name *fire*, *phlogiſton*, *caloric*, *heat*, or any other; or only indicates and meaſures certain ſtates or conditions, in which all bodies may be found, without the addition or abſtraction of any material ſubſtance.

We think that this queſtion has a greater chance now of being decided than in any former time, in conſequence of a recent and very important diſcovery made by that unwearied obſerver of the works of God, the celebrated Dr Herſchel. Being greatly incommoded when looking at the ſun, by the great heats produced in the eye-pieces of his teleſcopes, he thought that the laws of refraction enabled him to diminiſh them by a proper conſtruction of his eye-pieces. He began his attempts like a philoſopher, by examining the heat produced in the various parts of the priſmatic ſpectrum. Comparing the gradations of heat with that of illumination, he found that they did not, by any means, follow the ſame law. The illumination increaſed gradually from the violet end of the ſpectrum, where it was exceedingly faint, to the boundary of the green and yellow, where it was the moſt remarkable; and after this, it decreaſed as the illuminated object approached the red extremity of the ſpectrum. But the calorific power of the refracted light increaſed all the way from the extreme violet to the extreme red; and its laſt augmentations were conſiderable, and therefore unlike the uſual approaches of a quantity to its maximum ſtate. This made him think of placing the thermometer a little way beyond the extremity of the viſible ſpectrum. To his great aſtoniſhment, he found that the thermometer was more affected there than in the hotteſt part of the *illuminated* ſpectrum. Expoſing the thermometer at various diſtances beyond the extreme red, but in the plane of refraction, he found that it was moſt ſtrongly affected when placed beyond that extremity, about one-fifth of the whole length of the ſpectrum; from thence the calorific influence of the ſun gradually diminiſhed, but was ſtill very conſiderable at a diſtance from the extreme red equal to three-fifths of the length of the luminous ſpectrum. Theſe firſt ſuggeſted modes of trial appeared to Dr Herſchel to be too rude to intitle him to ſay that the warming influence did not extend ſtill farther. Indeed the inſtrument ſcarcely performed the part of a thermometer, but merely that of an indicator of heat, or a thermoſcope.

Here is a very new, and wonderful, and important, piece of information. We apprehend that all the philoſophers of Europe, as well as the unlearned of all nations, believe that the *warming* influence of the ſun, and of other luminous bodies, is conjoined with their power of *illumination*. Moſt of the philoſophers admitted the emiſſion of a matter called *light*, projected from the ſhining body, and moving with aſtoniſhing velocity, in thoſe lines which the mathematicians called *rays*, becauſe they diverged from the ſhining point, as the *radii* or ſpokes of a wheel diverge from the nave. This notion ſeems to be the ſimple ſuggeſtion of Nature; and it alſo ſeems to be the opinion entertained by Sir Iſaac Newton. His demonſtration of the laws of reflection and refraction proceeds on this ſuppoſition alone, and the particles of light are held by him to be affected by accelerating and deflecting forces, in the ſame way as a ſtone thrown from the hand is affected by gravity. Huyghens, indeed, Dr Hooke, and Euler, imagined that viſion and illumination were effected in the ſame way that hearing, and reſonance, and echo, are effected—that there is no matter projected from the ſhining body; but that we are ſurrounded by an elaſtic fluid, which is thrown into vibrations by certain tremors of the viſible object—and that thoſe vibrations of this fluid affect our eye in the ſame way as the undulation of elaſtic air, produced by the tremors of a ſtring or a bell, affect our ear. According to theſe philoſophers, a ray of viſion is merely the line which paſſes through all theſe undulations at right angles.

Theſe two opinions ſtill divide the mathematical philoſophers of Europe; but the majority, and particularly the moſt eminent for mathematical and mechanical ſcience, are (with the exception of Huyghens and Euler) on the ſide of the vulgar. This opinion has been greatly ſtrengthened of late years by the diſcoveries in chemiſtry. The influence of light on the growth of plants, the total want of aromatic oils in ſuch as grow in the dark, and their formation and appearance in the very ſame plant, along with the green colour, as ſoon as the plant is placed in the light (even that of open day without ſunſhine, or in the light of a candle,) is a ſtrong indication of ſome ſubſtance being obtained from the light, abſorbed by the plant, and combined with its other ingredients. The ſame concluſion is drawn from the effects of the ſun's light on vegetable colours, on the nitric and nitrous acids, on manganeſe, on the calces or oxyds of metals, and numberleſs other inſtances, which all concur in rendering it almoſt unqueſtionable that the ſun's rays, and thoſe of other ſhining bodies, may be, and daily are, combined with the other ſubſtances of which bodies are compoſed, and may be again ſeparated from them. And, ſhould any doubts remain, it would ſeem that the theory of combuſtion, firſt conceived and imperfectly publiſhed by Dr Hooke in his *Micrography*, p. 103. and in his *Lampas*, p. 1. &c. adopted by Mayow (ſee Hooke and Mayow in this *Suppl.*), forgotten, and lately revived and confirmed by Mr Lavoiſier, remove them entirely. In the beautiful and well-contrived experiments of the laſt gentleman, the light, accompanied by its heat, which had been abſorbed in the proceſs of growth or other natural operations, re-appeared in their primitive form, and might again be abſorbed and made to undergo the ſame round of changes.

Scheele, not inferior to Newton in caution, patience, and accuracy, and attentive to every thing that occurred in his experiments, diſcovered the ſeparability of the illuminating and the warming influences of ſhining bodies. He remarked, that a plate of glaſs, the moſt colourleſs and pellucid that can be procured, when ſuddenly interpoſed between a glowing fire and the face, inſtantly cuts off the warming power of the fire, without cauſing any ſenſible diminution of its brilliancy. He followed this diſcovery into many obvious conſequences, and found them all fully confirmed by obſervation and experiment. The writer of this article, immediately on hearing of Scheele's experiments, repeated them with complete ſucceſs: but he found, that when the glaſs plate had acquired the higheſt temperature which it could acquire in that ſituation, it did not any longer intercept the heat, or at leaſt in a very ſmall and almoſt inſenſible degree. It ſeemed to abſorb the heat, till ſaturated, without abſorbing any conſiderable portion of the light.

This ſeparability of heat from light does not ſeem to have met with the attention it deſerved. Dr Scheele's untenable theories on theſe ſubjects turned away the attention of the chemiſts from this diſcovery, and the mathematical philoſophers ſeem not to have heard of it at all. The late Dr Hutton of Edinburgh was more ſenſible of its importance; and in his laſt endeavours to ſupport the falling cauſe of phlogiſton, makes frequent alluſions to it. But in his attempts to explain the curious obſervations of Meſſrs Sauſſure and Pictet, in which there are unqueſtionable appearances of radiated heat, he reaſons ſo unconſequentially, that few readers proceed farther, ſo as to notice ſeveral obſervations of facts where the illuminating and warming influences are plainly ſeparated. In all theſe inſtances, however, Dr Hutton conſiders the inviſible rays as light, but not as heat; maintaining that they are inviſible, or do not render bodies viſible, only becauſe our eyes are inſenſible to their feeble action.

It was reſerved for Dr Herſchel to put this matter beyond diſpute by theſe valuable experiments. For did the inviſibility of any of the light beyond the extreme red of the priſmatic ſpectrum ariſe from the inſenſibility of our organs, the ſpectrum would gradually fade away beyond the red; but it ceaſes abruptly. Theſe thoughts could not eſcape this attentive obſerver. He therefore examined more particularly thoſe inviſible rays, cauſing them to be reflected by mirrors, and refracted through lenſes; and, in ſhort, he ſubjected them to all the ſubſequent treatments which Newton applied to the colouring rays. He found them retain their ſpecific refrangibilities and reflexibilities with as much uniformity and obſtinacy as Newton had obſerved in the colour-making rays. They were made to paſs through lenſes while the illuminating rays were intercepted by an opaque body, and the inviſible rays were then collected into a focus. They were reflected, both by the anterior and poſterior ſurfaces of tranſparent bodies. In all theſe trials they retained their power of expanding the liquor of a thermometer, and exciting the ſenſation of heat.

Theſe trials were not confined to the ſolar light or the ſolar rays: They were alſo made on the emanations from a candle, from an open fire, and from red hot iron; then they were made with bodies not hot enough to ſhine; with the heat of a common ſtove, and the heat from iron which was not viſible in the dark. The event was the ſame in all; and it was clearly proved that heat, or the cauſe of heat, is as ſuſceptible of radiation as light is; and that this radiation is performed in both according to the ſame laws.

We look with impatience for the ſubſequent experiments of this celebrated philoſopher on this ſubject; for we conſider them as of the greateſt and moſt extenſive importance for explaining the operations of Nature. We ſee, with indiſputable evidence, that there are rays from the ſun, and other bodies, which do not illuminate. It does not follow, however, that there are rays

rays which do not warm; for the thermometer was affected in every part of the coloured ſpectrum. Dr Herſchel ſeems to think that the power of affecting the organ of ſight depends on the particular degrees of mechanical momentum which are indicated by the different degrees of refrangibility. We confeſs that we think it unlikely that ſuch a power ſhould terminate abruptly. We do not obſerve this in analogous phenomena: the evaneſcence of our ſenſations of ſound, of muſical pitch, of heat, &c. are all gradual. We think it more likely that illuminating and warming are ſpecific effects of different things. We ſhould have entertained this opinion independent of all other experience; and we think it ſtrongly confirmed by the experiments of Dr Scheele already mentioned. We are diſpoſed therefore to believe that there are rays which illuminate, but which do not warm; and rays which warm without illuminating. We have experiments in proſpect, by which we hope to put this to the teſt.

Theſe experiments of Dr Herſchel afford another good argument for the common opinion concerning light, namely, that *it is a matter emitted from the ſhining body*, and not merely the undulations of an elaſtic medium; for if it were undulation, then, ſince there is heat in the yellow light, it would follow that a certain frequency of undulation produces, both the ſenſation of heat and the ſenſation of a yellow colour. In this caſe they ſhould be inſeparable.

This follows, in the ſtricteſt manner, from the principles or aſſumptions adopted by Euler in his mechanical theory of undulations. The chromatic differences in the rays of light are affirmed to ariſe entirely from the different frequencies of the aethereal undulations; and he endeavours to ſhew that theſe differences in frequency produces a difference in refrangibility. It is evident that this reaſoning is equally concluſive with reſpect to the calorific or heating power of the rays. The light and the heat are both undulations: theſe differ only in frequency; and this freqnency is indicated (according to Euler) by the refrangibility. There is a certain frequency therefore which excites the ſenſation of yellow. The ſame frequency, indicated by the ſame refrangibility, produces heat; therefore the frequency which produces this degree of heat alſo produces the ſenſation of yellow. We muſt not ſay that the momentum of the undulation may produce heat, but is inſufficient for the production of light, as a ſtring may vibrate too feebly for being heard; for we ſee, by Dr Herſchel's experiments, that, with a momentum ſufficient for making the moſt brilliant ſpectrum, there are rays (and thoſe which have the greateſt momentum) which produce heat, and yet are inviſible.

It does not follow, from any of Dr Herſchel's experiments, that the rays emitted by iron, which is not hot enough to ſhine in a dark room, have *all* the different degrees of refrangibility obſerved by him. Perhaps none of them would fall on the chromatic ſpectrum. We think, however, that this is not probable. It may be tried by collecting them to a focus by a lenſe, intercepting, however, all thoſe which are leſs refrangible than the red-making rays. We truſt that the thermometer in the focus will ſtill be affected.

This is but a very imperfect account of this important diſcovery; but we thought that it would be highly intereſting to our readers. The preſs was employed on this very ſheet when we received the information from a friend, who had ſeen Dr Herſchel's Diſſertation, which will appear in the firſt volume publiſhed by the Royal Society. We truſt that the ingenious author will ſoon follow it up with the inveſtigation of the ſubject in all its conſequences.

We hope that he will examine what will reſult from mixing ſome of the inviſible rays with ſome of the coloured ones. We know that the yellow and the blue, when mixed, produce the ſenſation of green. Perhaps the inviſible rays may alſo change the appearance. We do not, however, expect this.

We alſo hope that Dr Herſchel will examine whether the inviſible rays of the ſun produce any effect on vegetable colours; whether they blacken the calces of ſilver and biſmuth, luna cornea, and decompoſe the nitrous and the oxygenated muriatic acid, &c. &c. We ſhould thus get more inſight into the nature of caloric and of combuſtion. Combuſtion may perhaps be reſtored to its rank in the phenomena of Nature, and no longer be ſunk in the general gulph of oxygenation, and thus obliterated from the memory of chemiſts. It is perhaps the moſt remarkable phenomenon of material Nature; and *fire* and burning will never go out of the language of plain men. Fire, and all its concomitants, have, in all times, been conſidered as even the *chief* objects of chemical attention; and an unlearned perſon will ſtare, when a chemiſt tells him that there is no ſuch thing, and that what he calls the burning of a piece of coal is only the making it ſour. He will perhaps ſmile; but it will not be a ſmile of aſſent.

It was one darling object of the Revolutionary Committee of Chemiſts, aſſembled at Paris in 1787, to baniſh from our minds, *by means of a new language*, all remembrance of any thing which we did not derive from the philoſophers of France. We think ourſelves in a condition to prove this by letters to this country from the ſcene of action; in which the expected victory is ſpoken of in terms of exultation, and with ſo little reſtraint, that the writer forgets that it is Dr Black whom he is informing that *l'air fixe* and *le pauvre phlogiſtique* will ſoon be forgotten; and yet the writer was a gentleman of uncommon modeſty and worth, and ſincerely attached to Dr Black. We give this as a remarkable inſtance of the *eſprit de corps*, and of the nature and towering ambition of that nation. From this they have not ſwerved; and they hope to gain this ſummit of ſcientific dominion in the ſame way as *the ſame philoſophers* hope to baniſh Chriſtianity by means of their new kalendar. It may, however, turn out that both Dr Hooke and Mr Lavoiſier are miſtaken, when they make the oxygen gas the ſole ſource of both the light and the heat which accompany combuſtion. One of them may perhaps be furniſhed by the body which all, except the new philoſophers, call combuſtible.

The objections which may be made to the theory of Huyghens and Euler, on the acknowledged principles of mechanics, appear to us unanſwerable. Euler has never attempted to anſwer thoſe taken from the different diſperſing powers of different ſubſtances. The objections made to the Newtonian, or vulgar theory of emiſſion, are not ſuch as imply abſurdity; they are only difficulties. The chief of them, *viz.* the ſameneſs of velocity in all lights whatever, is of this kind. It is merely an improbability. But the objections to the theory

Thermometric.

theory of undulation, deduced from the chemical effects of light, are not less strong than those deduced from mechanical principles. It is quite inconceivable that the undulation of a medium, which pervades all bodies, shall produce aromatic oils in some, a green fæcula in others, shall change sulphuric acid into sulphur, &c. &c. No effects are produced by the undulations of air, or the tremors of elastic bodies, which have the most distant analogy or resemblance to these.

That the sun and other shining bodies emit the matter of light and heat, seems therefore to merit the general reception which it meets with from the philosophers. But even of this class there are differences in opinion. Some imagine that light only is emitted, and that the heat which we feel is occasioned by the action of the luminous rays on our atmosphere, or on the ground. Were the sun's calorific rays as dense at the surface of the sun as his luminous rays are, the heat there must exceed (say they) all that we can form any conception of. Yet we see, that when the nucleus of the sun is laid bare by some natural operation, which, like a volcanic explosion, throws aside the luminous ocean which covers it to a prodigious depth, the naked parts of this nucleus are black. Therefore the intense heat in that place is not able to make it shining hot, as it does in all our experiments with intense heats, giving a dazzling glare. This is thought highly improbable; and it is therefore supposed that there is, primitively, no heat in the sun's rays, but that they act on our air, or other terrestrial matter, combining with it, and disengaging heat from it, or producing that particular state and condition which we call *heat*.

We think that Dr Herschel's discovery militates strongly and irresistibly against this opinion; and shews, that whatever reason we have for saying that the sun's rays bring light from the sun we have the same authority for saying, that they bring heat, fire, caloric, phlogiston, or by whatever other name we choose to distinguish the cause of warmth, expansion, liquefaction, ebullition, &c.

We must either say that light and heat are not substances of a peculiar kind, susceptible of union with the other ingredients of bodies, but merely a state of undulation of an elastic medium, as sound is the undulation of air; or we must say that the sun's rays contain light and heat, in a detached state, fit for appearing in their simplest form, producing illumination and expansion, and for uniting chemically with other matter. Whichever of these opinions we adopt, it is pretty clear that all attempts to discover a difference in the weight of hot and cold bodies may be given over. In the first case, it is self-evident; in the second, we have abundant evidence, that if light and heat, being gravitating matter like all other bodies, were added to, or abstracted from bodies, in sufficient quantity to be sensibly heavy, the rays of the sun, or even the light of a candle, would occasion instant destruction by its mere momentum; since every particle of radiated light and heat moves at the rate of 200,000 miles in a second.

This discovery of Dr Herschel's adds greatly to the probability of the opinion which we expressed on another occasion, that the forces of powers of natural substances, which are the immediate causes of the chemical phenomena, are no way different from the mechanical forces which render bodies heavy, coherent, elastic, expansive, &c.; in short, that they are what we call *accelerating forces*. We deduced this from the fact, that mechanical force can be opposed to them, so as to prevent their action in circumstances where it would otherwise certainly take place. Thus, by external pressure, we can prevent that union of water and caloric which would convert it into elastic steam. We can even disunite them again, when steam is already produced, by forcibly condensing it into a smaller space. Now, the refraction and reflection of heat are performed according to the same precise laws which we observe in the refraction and reflection of light; and Sir Isaac Newton has demonstrated that those phenomena arise from the action of accelerating forces, whose direction is perpendicular to the acting surfaces. The matter of heat, therefore, is like other matter in its mechanical properties; and, in the motion of refraction, it is acted on and deflected, just as a projectile is acted on and deflected by gravity. It continues in motion till its velocity and direction are changed by deflecting forces, exerted by the particles of the transparent medium or the reflecting surface. It would take up too much room, but it is a very easy process, to demonstrate that this regular refraction of heat is altogether incompatible with the usually supposed notion of caloric; namely, that it is an expansive fluid like air, but incomparably more elastic; from which property very plausible explanations have been given of the elasticity of gases, steams, and such like fluids. Every intelligent mechanician will be sensible that all this sort of chemical science falls to the ground, when it is proved, by exhibition of the fact, that radiated heat is refracted in the same way with radiated light. We must look for the explanation of the immense explosive force of fulminating silver, gold, &c. in some very different principles from those which are now in vogue. We apprehend, too, that the very phenomenon of this refraction gives indication of forces which are sufficiently powerful for this explanation: For when we reflect on the astonishing velocity of the ray of heat; on the minute space along which it is deflected, and consequently the time of this action, minute beyond all imagination; and when we compare those circumstances with a deflection produced by gravity in the motion of a projectile—it is evident that the deflecting force of refraction must exceed the greatest force that we have any knowledge of, in a greater proportion than the weight of Mount Ætna exceeds that of a particle of sand. We would desire Mr de la Place to suspend his hopes of establishing universal fatalism, till he can reconcile these phenomena with his fundamental principle, "*that all forces which are diffused from a single point, necessarily and essentially diminish in the inverse duplicate ratio of the distances*." Till he can do this, he had better still allow, with Newton, that the selection of the duplicate ratio for the action of gravity (by which alone the solar system can be rendered permanent and orderly) is a mark of wisdom and benevolence. We would advise him to reconcile his mind to this; and perhaps, like the modest and admiring Newton, he may, in good time, find comfort in the thought.

It is also highly worthy of remark, that this refracting force, almost immense, which is so plainly exerted between the particles of bodies and light, when considered as of the same kind with those that produce chemical union, appears abundantly sufficient for explaining some

some of the most wonderful phenomena of chemistry; such as the prodigious elasticity of steam, of gunpowder, and the still more astonishing explosion of fulminating gold and silver. Some of the phenomena of deflected light are produced by these optical forces acting at distances sufficiently great to admit of measurement; as in the Newtonian observations on the passage of light near the edges of opaque bodies. These deflections enable us to compare the deflecting forces with gravity. The *refracting* force, however, is vastly greater than even this, as may be seen by the greater deflection which is produced by it; and, being exerted along a space incomparably smaller, it must be greater still. Here, then, are forces fully adequate to the phenomena of fulmination. And we would again desire Mr de la Place to remark that, although these exploding forces are irresistible, their action seems to vanish entirely beyond the limits of mathematical contact. This is plain from the fact, that those explosions do not project the fragments to great distances. This is remarkably the case in all the most eminent of them. Common or nitric gunpowder is perhaps the only great exception. This particular circumstance will surely suggest to this eminent analyst the *inverse triplicate* ratio of the distance as more likely to explain the phenomena than his favourite law.

We trust that our readers will not be displeased with this short sketch of Dr Herschel's discovery, and the few reflections which it naturally suggested to our minds. We shall not be greatly surprised, although it should produce a sort of counter-revolution in chemical science, in consequence of new conceptions which it may give us of the union of bodies with light and heat. The phenomena of the vegetable and animal economy shew that they are susceptible of combination with other substances besides the basis of vital air. Whatever changes this may produce in the great revolution which has already taken place in chemical science, they will (in our opinion) be favourable to true philosophy; because Dr Herschel's discovery co-operates with other arguments of sound mathematical reasoning, to overturn that principle on which De la Place hopes to found his atheistical doctrine of fate and necessity. It contributes therefore to restore to the face of Nature that smiling feature of providential WISDOM which Newton had the honour of exhibiting to the view of rational men. The sun is the source of light and genial warmth to a vast system, which is held together, in almost eternal order and beauty, by a law of attraction selected by Infinite Wisdom, as the only one adequate to this magnificent purpose.

THEVENOT (Melchisedec), librarian to the king of France, and a celebrated writer of travels, was born at Paris in 1621, and had scarcely gone through his academical studies, when he discovered a strong passion for visiting foreign countries. At first he saw only part of Europe; but then he took great care to procure very particular informations and memoirs from those who had travelled over other parts of the globe, and out of those composed his "Voyages and Travels."—He laid down among other things, some rules, together with the invention of an instrument, for the better finding out of the longitude, and the declination of the needle; and some have thought that these are the best things in his works, since travels, related at second hand, can never be thought of any great authority or moment; not but Thevenot travelled enough to relate some things upon his own knowledge. Another passion in him, equally strong with that for travelling, was to collect scarce books in all sciences, especially in philosophy, mathematics, and history; and in this he may be said to have spent his whole life. When he had the care of the King's library, though it was one of the best furnished in Europe, he found 2000 volumes wanting in it which he had in his own. Besides printed books, he bought a great many manuscripts in French, English, Spanish, Italian, Latin, Greek, Hebrew, Syriac, Arabic, Turkish, and Persic. The marbles presented to him by Mr Nointel, at his return from his embassy to Constantinople, upon which there are bass-reliefs and inscriptions almost 2000 years old, may be reckoned among the curiosities of his library. He spent most of his time among his books, without aiming at any post of figure or profit: he had, however, two honourable employments; for he assisted at a conclave held after the death of Pope Innocent X. and was the French king's envoy at Genoa. He was attacked with what is called a slow fever in 1692, and died October the same year, at the age of 71. According to the account given, he managed himself very improperly in this illness; for he diminished his strength by abstinence, while he should have increased it with hearty food and generous wines, which were yet the more necessary on account of his great age.—Thevenot's Travels into the Levant, &c. were published in English in the year 1687, folio; they had been published in French at Paris 1663, folio. He wrote also "L'Art de Nager," the Art of Swimming, 12mo, 1696.

THOMAS (Christian) was born at Leipsic 1655, and was well educated, first under his father, and afterwards in the Leipsic university. At first he acquiesced in the established doctrines of the schools; but upon reading Puffendorf's "Apology for rejecting the Scholastic Principles of Morals and Law," light suddenly burst upon his mind, and he determined to renounce all implicit deference to ancient dogmas. He read lectures upon the subject of Natural Law, first from the text of Grotius, and afterwards from that of Puffendorf, freely exercising his own judgment, and, where he saw reason, advancing new opinions. Whilst his father was living, paternal prudence and moderation restrained the natural vehemence and acrimony of the young man's temper, which was too apt to break out, even in his public lectures. But when he was left to himself, the boldness with which he advanced unpopular tenets, and the severity with which he dealt out his satirical censures, soon brought upon him the violent resentment of theologians and professors.

An "Introduction to Puffendorf," which Thomas published in the year 1687, wherein he deduced the obligation of morality from natural principles, occasioned great offence. The following year he became still more unpopular, by opening a monthly literary journal, which he intitled "Free Thoughts, or Monthly Dialogues on various Books, chiefly new;" in which he attacked many of his contemporaries with great severity. The raillery of this satirical work was too provoking to be endured: complaints were lodged before the ecclesiastical court of Dresden; the bookseller was called upon to give up the author; and it was only through the interest

tereſt of the Mareſchal that Thomas eſcaped puniſhment. The title of the work was now changed; but its ſpirit remained. A humours and ſatirical life of Ariſtotle, and ſeveral other ſarcaſtic papers, kept alive the flame of reſentment, till at length it again burſt forth, on a charge brought againſt him before the ſame court by the clergy of Leipſic, for contempt of religion; but he defended himſelf with ſuch ability, that none of his adverſaries choſe to reply, and the matter was dropped.

A ſatirical review, which he wrote, of a treatiſe "On the Divine Right of Kings," publiſhed by a Daniſh divine; "A Defence of the Sect of the Pictiſts," and other eccentric and ſatirical publications, at laſt inflamed the reſentment of the clergy againſt Thomas to ſuch a degree, that he was threatened with impriſonment. To eſcape the ſtorm which thickened about him, he entreated permiſſion from the Elector of Brandenburg, in whoſe court he had ſeveral friends, that he might read private lectures in the city of Hall. This indulgence being obtained. Thomas became a voluntary exile from Leipſic. After a ſhort interval, he was appointed public profeſſor of juriſprudence, firſt in Berlin, and afterwards at Hall. In theſe ſituations, he found himſelf at full liberty to indulge his ſatirical humour, and to engage in the controverſies of the times: and as long as he lived, he continued to make uſe of this liberty in a manner which ſubjected him to much odium. At the ſame time, he perſevered in his endeavours to correct and ſubdue the prejudices of mankind, and to improve the ſtate of philoſophy. He died at Hall in the year 1728.

Beſides the ſatirical journal already mentioned, Thomas wrote ſeveral treatiſes on logic, morals, and juriſprudence; in which he advanced many dogmas contrary to received opinions. In his writings on phyſics, he leaves the ground of experiment and rational inveſtigation, and appears among the myſtics. His later pieces are in many particulars inconſiſtent with the former.—His principal philoſophical works are, "An Introduction to Aulic Philoſophy, or Outlines of the Art of Thinking and Reaſoning;" "Introduction to Rational Philoſophy;" "A Logical Praxis;" "Introduction to Moral Philoſophy;" "A Cure for Irregular Paſſions, and the Doctrine of Self-Knowledge;" "The new Art of diſcovering the ſecret Thoughts of Men;" "Divine Juriſprudence;" "Foundations of the Law of Nature and Nations;" "Diſſertation on the Crime of Magic;" "Eſſay on the Nature and Eſſence of Spirit, or Principles of Natural and Moral Science;" "Hiſtory of Wiſdom and Folly."

From the ſpecimen given by Dr Enfield of his more peculiar tenets (for we have read none of his books), Thomas appears to have been a man of wonderful inconſiſtency in his opinions; teaching on one ſubject rational piety and true ſcience, and on another abſurdity and atheiſm. "No other rule (he ſays) is neceſſary in reaſoning, than that of following the natural order of inveſtigation; beginning with thoſe things which are beſt known, and proceeding, by eaſy ſteps, to thoſe which are more difficult." This is perfectly conſiſtent with the foundation of the Baconian logic; and is indeed the only foundation upon which a ſyſtem of ſcience can poſſibly be built. Yet could the man, who profeſſes to proceed from a principle ſo well eſtabliſhed, gravely advance, as concluſions of ſcience, the following abſurdities: "Perception is a paſſive affection, produced by ſome external object, either in the intellectual ſenſe, or the inclination of the will. God is not perceived by the intellectual ſenſe, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God: nothing is exterior to him. Creation is extenſion produced from nothing by the divine power. Creatures are of two kinds, paſſive and active; the former is matter, the latter ſpirit. Matter is dark and cold, and capable of being acted upon by ſpirit, which is light, warm, and active. Spirit may ſubſiſt without matter, but deſires a union with it. All bodies conſiſt of matter and ſpirit, and have therefore ſome kind of life. Spirit attracts ſpirit, and thus ſenſibly operates upon matter united to ſpirit. This attraction in man is called *love;* in other bodies *ſympathy*. A finite ſpirit may be conſidered as a limited ſphere, in which rays, luminous, warm, and active flow from a centre. Spirit is the region of the body to which it is united. The region of finite ſpirits is God. The human ſoul is a ray from the divine nature; whence it deſires union with God, who is love. Since the eſſence of ſpirit conſiſts in action, and of body in paſſion, ſpirit may exiſt without thought; of this kind are light, ether, and other active principles in nature." Fortunately, this jargon is as unintelligible as the categories of Kant, and the blaſphemies of Spinoza; for an account of which the reader is referred to *Critical* PHILOSOPHY in this *Suppl.* and to SPINOZA in the *Encycl.*

THORNTON (Bonnel), a modern poet, the intimate friend of Lloyd and Colman, and juſtly claſſed with them in point of talents, was born in Maiden-lane, London, in the year 1724. He was the ſon of an apothecary; and being educated at Weſtminſter ſchool, was elected to Chriſt-Church, Oxford, in the year 1743. He was thus eight years ſenior to Colman, who was elected off in 1751. The firſt publication in which he was concerned was, "The Student, or Oxford and Cambridge Miſcellany," which appeared in monthly numbers; and was collected in two volumes 8vo, in 1748. Smart was the chief conductor of the work; but Thornton, and other wits of both univerſities, aſſiſted in it. He took his degree of maſter of arts in 1750; and as his father wiſhed him to make phyſic his profeſſion, he took the degree of bachelor of that faculty in 1754. In the ſame year he undertook the periodical paper called *The Connoiſſeur*, in conjunction with Colman, which they continued weekly to the 30th of September 1756. In the concluding paper, the different ages and purſuits of the two authors are thus jocularly pointed out, in the deſcription of the double author, Mr Town. "Mr Town is a fair, black, middle ſized, very ſhort man. He wears his own hair and a periwig. He is about thirty years of age (literally thirty-two), and not more than four-and-twenty. He is a ſtudent of the law and a bachelor of phyſic. He was bred at the univerſity of Oxford, where, having taken no leſs than three degrees, he looks down on many learned profeſſors as his inferiors; yet having been there but little longer than to take the firſt degree of bachelor of arts, it has more than once happened that the cenſor-general of all England has been reprimanded by the cenſor of his college, for neglecting to furniſh the uſual eſſay, or, in the collegiate phraſe, the theme of

Biograph. Dictionary.

of the week." Engaged in purfuits of this kind, Bonnel Thornton did not very clofely follow the profeffion to which his father deftined him, but lived rather a literary life, employing his pen on various fubjects. To the daily paper called the *Public Advertifer*, then in high reputation, he was a frequent contributor; and he once had it in contemplation to treat with Mr Ritch for the patent of Covent Garden theatre. In 1764, Mr Thornton married Mifs Sylvia Brathwaite, youngeft daughter of Colonel Brathwaite, who had been governor of a fort in Africa. In 1766, encouraged, as he fays himfelf, by the fuccefs of his friend Colman's Terence, he publifhed two volumes of a tranflation of Plautus in blank verfe; propofing to complete the whole if that fpecimen fhould be approved. Thefe volumes contained feven plays, of which the *Captive* was tranflated by Mr Warner, who afterwards completed all that Thornton had left unfinifhed; and the *Mercator* by Mr Colman. The remaining five are, the *Amphitryon*, *Miles Gloriofus*, *Trinummus*, *Aulularia*, *Rudens*. Some parts of the remaining plays which Thornton had tranflated are preferved by his continuator. There can be no doubt that this is the beft way of tranflating the old comedies, and that Thornton was well qualified for the tafk; but the work has never been in high favour with the public. Yet Warburton faid of it, that "he never read fo juft a tranflation, in fo pure and elegant a ftyle." Thornton publifhed in 1767, *The Battle of the Wigs*, as an additional canto to Garth's Difpenfary; the fubject of which was the difputes then fubfifting between the fellows and licentiates.

The life of Thornton was not deftined to attain any great extenfion: in the prime of his days, while he was furrounded by domeftic felicity, the comforts of fortune, and the refpect of fociety, ill health came upon him; and medical aid proving inefficient, he died, of the gout in his ftomach, May 9, 1768, at only 44 years of age. His wife, a daughter, and two fons, furvived him. Befides the productions already mentioned, he wrote the papers in the Adventurer marked A; "An Ode to St Cecilia's day, adapted to the ancient Britifh Mufic," a burlefque performance; "The Oxford Barber;" with many detached effays in the public papers. A few letters addreffed to his Sylvia before they were married, difplay great tendernefs, expreffed with franknefs and eafe. A fmall edition of his works might, with much propriety, be prefented to the public, before it fhall be too late to afcertain them all. His character may be taken from his epitaph, written in Latin by his friend Dr Warton, and placed on his monument in Weftminfter Abbey. It is to this effect: "His genius, cultivated moft happily by every kind of polite literature, was accompanied and recommended by manners open, fincere, and candid. In his writings and converfation he had a wonderful livelinefs, with a vein of pleafantry peculiarly his own. In ridiculing the failings of men, without bitternefs, and with much humour, he was fingularly happy; as a companion, he was delightful."

THETFORD, a townfhip in the fouth-eaft corner of Orange county, Vermont, on the weftern bank of Connecticut river, about 10 miles north of Dartmouth College, and contains 862 inhabitants.—*Morse*.

THOMAS's *Bay*, on the W. coaft of the ifland of Antigua. It affords fome fhelter from the S. and S. E. winds.—*ib.*

Thomas *Ifland, St*, or the *Danes Ifland*, is the largeft and moft northerly of the Virgin Iflands, in the Weft-Indies, and is about 9 miles long and 3 broad. It has a fandy foil and is badly watered, but enjoys a confiderable trade, efpecially in time of peace, in the contraband way; and privateers in time of war fell their prizes here. A large battery has been erected for its defence, mounted with twenty pieces of cannon, N. lat. 18 22, W. long. 64 51. It has a fafe and commodious harbour, and lies about 30 miles eaft of the ifland of Porto Rico.—*ib.*

Thomas *Ifland, St*, on the weft coaft of New-Mexico. N. lat. 20 10, weft long. 113 5.—*ib.*

Thomas, *St*, a town of Guiana in S. America, fituated on the banks of the Oroonoko. N. lat. 75, weft long. 62 36.—*ib.*

Thomas, *Port St*, a harbour in the bay of Honduras, on the Spanifh Main; from which goods are fhipped to Europe.—*ib.*

Thomas, *St*, the chief town of New-Andalufia, or Paria, in the northern divifion of Terra Firma.—*ib.*

Thomas, *St*, a parifh of Charlefton diftrict, in S. Carolina. It contains 3,836 inhabitants; of whom 397 are whites, and 3,405 flaves.—*ib.*

THOMASTOWN, a poft-town of the Diftrict of Maine, Lincoln county, on the weft fide of Penobfcot Bay, and about 4 leagues from Franklin Ifland, at the mouth of the river St George, which divides this town from Warren and Cufhing, to the weftward. A confiderable river in the fouth-eaft part of the townfhip is called Weffoweffgeeg. From the hill of Madambettocks may be feen iflands and lands to a great diftance; and near it there is thought to be plenty of iron ore; but no attempts have been made to afcertain its quality. The grand ftaples of Thomaftown are lime and lumber. Lime-ftone is very common, and fpots of land, or rather rock, of fix rods fquare, are frequently fold for 100 dollars. There are now about 35 kilns erected, each of which, on an average, will produce 200 fifty gallon cafks. Thefe kilns, if burned only three times a year, (though many are 5 or 6 times) will furnifh about 21,000 cafks; which neat, after all expenfes, about fix fhillings a cafk. Too much attention being paid to this bufinefs, prevents a due cultivation of the lands. There are now owned on the river 12 brigs, fchooners, and floops, equal to about 1,100 tons, employed in foreign and coafting voyages. On the river, and its feveral ftreams, are a number of tide and other grift and faw mills, which afford great profit to their owners. A fort with a number of cannon, and a regular garrifon of provincials, was formerly ftationed about five miles below the head of the tide. Few veftiges of the fort now remain; but in place of it an elegant building was erected in 1794, by the Hon. Henry Knox, Efq. The fettlement of Thomaftown began about 1720, in 1777 it was incorporated, in 1790 it contained 801 inhabitants; and it was computed to contain in 1796 above 1,200. There are here no public fchools conftantly kept, though there are feveral private ones throughout the year. There are two churches, the one for Baptifts, who are the moft numerous, and the other for Congregationalifts. Here is alfo a focial library. The compact

pact part of the town is 7 miles southerly of Camden, 7 east of Warren, 39 N. E. by E. of Wiscasset, 215 N. E. of Boston, and 564 N. E. of Philadelphia.—*ib.*

THOME, *St*, or *St Thomas*, a plain in the centre of the island of St Domingo, in the West Indies, on the south side of the first chain of the mountains of Cibao, near which Artibonite river takes its rise. It is contiguous to the north of that of St John of Maguana. The fort of St Thomas was erected here, near the head of the Artibonite, by Christopher Columbus to protect the mines against the Indians. There is now no vestige of the fort remaining.—*ib.*

THOMPSON, a township of Windham county, in the north east corner of Connecticut; having the town of Killingly on the south, the state of Rhode-Island east, and that of Massachusetts on the north; from which last it receives Quinabaug and Five-mile rivers. —*ib.*

THOPICANOS, a small river of the N. W. Territory, which runs southward to Wabash river, into which it enters a few miles eastward of Ouixtanon. —*ib.*

THORNTON, a township of New-Hampshire, in Grafton county, at the head of Merrimack river, which contains 385 inhabitants. It was incorporated in 1781. —*ib.*

THOULOUSE, *Port*, on the south coast of the island of Cape Breton, near the entrance of the Strait of Fronsac or Canso, lies between the gulf called Little St Peter and the islands of St Peter. It was formerly called Port St Peter, and is 60 miles west of Gabaron Bay. —*ib.*

THOUSAND *Isles* are situated in St Lawrence, or Iroquois river, a little north of Lake Ontario.—*ib.*

THOUSAND *Lakes*, a name given to a great number of small lakes near the Mississippi, a little to the N. E. of St Francis river, which is about 60 miles above St Anthony's Falls. The country about these lakes, though but little frequented, is the best within many miles for hunting; as the hunter seldom fails returning loaded beyond his expectation. Here the river Mississippi is not above 90 yards wide.—*ib.*

THREE *Brothers*, 3 islands within the river Essequibo on the east coast of S. America.—*ib.*

THREE *Islands Bay*, or *Harbour*, on the east coast of the Island of St Lucia, in the West Indies.—*ib.*

THREE *Points*, *Cape*, on the coast of Guiana, in S. America. N. lat. 10 38, W. long. 61 57.—*ib.*

THREE *Sisters*, three small isles on the west shore of Chesapeak Bay, which lie between West river and Parker's Island.—*ib.*

THRUM *Cap*, in the S. Pacific Ocean, a small circular isle, not more than a mile in circumference, seven leagues N. 62° W. from Lagoon Island. High water, at full and change, between 11 and 12 o'clock. S. lat. 18 35, W. long. 139 48.—*ib.*

THULE, *Southern*, an island in the S. Atlantic Ocean, the most southerly land ever discovered; hence the name. S. lat. 59 34, W. long. 27 45.—*ib.*

THUNDER. There is not one of the appearances of nature which has so much engaged the attention of mankind as thunder. The savage, the citizen, and the philosopher, have observed it with dread, with anxiety, and with curiosity; and the philosopher of our times treats the others with a smile of condescension, while he here enjoys the fullest triumph of his superiority:

Felix qui potuit rerum cognoscere causas,
Atque metus omnes et inevitabile fulmen
Subjecit pedibus.

But though this grand phenomenon has long engaged the curious attention of philosophers, it is but very lately that they have been able to explain it; that is, to point out the more general law of nature of which it is a particular instance. Inflammable vapours had long furnished them with a sort of explanation. The discovery of gunpowder, and still more that of inflammable air, gave some probability to the existence of extensive strata of inflammable vapours in the upper regions of the atmosphere, which, being set on fire at one end, might burn away in rapid succession, like a train of gunpowder. But the smallest investigation would shew such a dissimilarity in the phenomena, and in the general effects, that this explanation can have no value in the eyes of a true naturalist. Horrid explosion, and a blast which would sweep every thing from the surface of the earth, must be the effects of such inflammation. The very limited and capricious nature of the ravages made by thunder, render them altogether unlike explosions of elastic fluids.

2 Thunder resembles the electrical shock.

No sooner were the wonderful effects of the charged electrical phial observed, than naturalists began to think of this as exhibiting some resemblance to a thunder-stroke (see ELECTRICITY, *Encycl.* n° 12.); but it was not till toward the year 1750 that this resemblance was viewed in a proper light by the celebrated Franklin. In a dissertation written that year, he delivers his opinion at large, and notices particularly the following circumstances of similarity.

In several remarkable particulars.

1. The colour and crooked form of lightning, perfectly similar to that of a vivid electrical spark between distant bodies, and unlike every other appearance of light. This angular, desultory, capricious form of an electrical spark, and of forked lightning, is very singular. No two successive sparks have the same form. Their sharp angles are unlike every appearance of motion through unresisting air. Such motions are always curvilineal. The spark is like the simultaneous existence of the light in all its parts; and the fact is, that no person can positively say in which direction it moves.

2. Lightning, like electricity, always strikes the most advanced objects—hills, trees, steeples.

3. Lightning affects to take the best conductors of electricity. Bell wires are very frequently destroyed by it. At Leven house in Fifeshire, in 1733, it ran along a gilded moulding from one end of the house to the other, exploding it all the way, as also the tinfoil on the backs of several mirrors, and the gilding of screens and leather hangings.

4. It burns, explodes, and destroys these conductors precisely as electricity does. It dissolves metals; melts wires; it explodes and tears to pieces bodies which contain moisture. When a person is killed by lightning, his shoes are commonly burst. When it falls on a wet surface, it spreads along it. The Royal William, in Louisburgh harbour, in 1758, received a thunder-stroke, which dissipated the maintop-gallant mast in dust, and came down on the wet decks in one spark, which

which ſpread over the whole deck as a ſpout of water would have done. This is quite according to electrical laws.

5. It has ſometimes ſtruck a perſon blind. Electricity has done the ſame to a chicken which it did not kill.

6. It affects the nervous ſyſtem in a way reſembling ſome of the known effects of electricity. The following is a moſt remarkable inſtance: —— Campbell, Eſq. of Succoth, in Dunbartonſhire, has been blind, for ſeveral years. The diſorder was a gutta ſerena. He was led one evening along the ſtreets of Glaſgow by his ſervant Alexander Dick, during a terrible thunder ſtorm. The lightning ſometimes fluttered along the ſtreets for a quarter of a minute without ceaſing. While this fluttering laſted, Mr Campbell ſaw the ſtreet diſtinctly, and the changes which had been made in that part by taking down one of the city gates. When the ſtorm was over, his entire blindneſs returned.—We have from a friend another inſtance, no leſs remarkable. One evening in autumn he was ſitting with a gentleman who had the ſame diſorder, and he obſerved ſeveral lambent flaſhes of lightning. Their faces were turned to the parlour window; and immediately after a flaſh, the gentleman ſaid to his wife "Go, my dear, make them ſhut the white gate; it is open, you ſee." The lady did ſo, and returned; and, after a little, ſaid, "But how did you know that the gate was open?" He exclaimed, "My God! I ſaw it open, and two men look in, and go away again," (which our friend alſo had obſerved). The gentleman on being cloſe queſtioned, could not recollect having had another glance, nor why it had not ſurpriſed him; but of the glimpſe itſelf he was certain, and deſcribed the appearance very exactly.

7. Lightning kills; and the appearances perfectly reſemble thoſe of a mortal ſtroke of electricity. The muſcles are all in a ſtate of perfect relaxation, even in thoſe ſituations where it is uſually otherwiſe.

8. Lightning is well known to deſtroy and to change the polarity of the mariner's needle.

3
[F]rank-[lin's d]iſco-[very an]d that [h]as the [...].

Dr Franklin was not contented with the bare obſervation of theſe important reſemblances. He availed himſelf of many curious diſcoveries which he had made of electrical laws. In particular, having obſerved that electricity was drawn off at a great diſtance, and without the leaſt violence of action, by a ſharp metallic point, he propoſed to philoſophers to erect a tall maſt or pole on the higheſt part of a building, and to furniſh the top of it with a fine metalline point, properly inſulated, with a wire leading to an inſulated apparatus for exhibiting the common electrical appearances. To the whole of this contrivance he gave the name of *thunder-rod*, which it ſtill retains. He had not a proper opportunity of doing this himſelf at the time of writing his diſſertation in a letter from Philadelphia to the Royal Society of London; but the contents were ſo ſcientific, and ſo intereſting, that in a few weeks time they were known over all Europe. His directions were followed in many places. In particular, the French academicians, encouraged by the preſence of their monarch, and the great ſatisfaction which he expreſſed at the repetition of Dr Franklin's moſt inſtructive experiments, which diſcovered and eſtabliſhed the theory of poſitive and negative electricity, as it is ſtill received, were eager to execute his orders, making his grand experiment, which promiſed ſo fairly to bring this tremendous operation of nature not only within the pale of ſcience, but within the management of human power.

But, in the mean time, Dr Franklin, impatient of delay, and perhaps incited by the honourable deſire of well-deſerved fame, put his own ſcheme in practice. His inventive mind ſuggeſted to him a moſt ingenious method of preſenting a point to a thunder cloud at a very great diſtance from the ground. This was by fixing his point on the head of a paper kite, which the wind ſhould raiſe to the clouds, while the wet ſtring that held it ſhould ſerve for a conductor of the electricity. We preſume that it was with a palpitating heart that Dr Franklin, unknown to the neighbours, and accompanied only by his ſon, went into the fields, and ſent up his meſſenger that was to bring him ſuch news from the heavens. He told a perſon, who repeated it in the hearing of the preſent writer, that when he ſaw the fibres of the cord raiſe themſelves up like hogs briſtles, he uttered a deep ſigh, and would have wiſhed that moment of joy to have been his laſt. He obtained but a few faint ſparks from his apparatus that day; but returned to his houſe in a ſtate of perfect happineſs, now feeling that his name was never to die. Thus did the ſoap bubble, and the paper kite, from being the playthings of children, become, in the hands of Newton, and of Franklin, the means of acquiring immortal honour, and of doing the moſt important ſervice to ſociety.

We may juſtly conſider this as one of the greateſt of philoſophical diſcoveries, and as doing the higheſt honour to the inventor; for it was not a ſuggeſtion from an accidental obſervation, but aroſe from a ſcientific compariſon of facts, and a ſagacious application of the doctrine of poſitive and negative electricity: a doctrine wholly Dr Franklin's, and the reſult of the moſt acute and diſcriminating obſervation. It was this alone that ſuggeſted the whole; and by explaining to his ſatisfaction the curious property of ſharp points, gave him the courage to handle the thunderbolt of Jove.

It is then a point fully aſcertained, that thunder and lightning are the electric ſnap and ſpark, as much ſuperior to our puny imitations as we can conceive from the immenſe extent of the inſtruments in the hands of Nature. If, ſays Dr Franklin, a conductor one foot thick and five feet long will produce ſuch ſnaps as agitate the whole human frame, what may we not expect from a ſurface of 10,000 acres of electrified clouds? How loud muſt be the exploſion? how terrible the effects?

This diſcovery immediately directed the attention of philoſophers to the ſtate of the atmoſphere with reſpect to electricity; and in this alſo Dr Franklin led the way. He immediately erected his thunder rods; and they have been imitated all over the world, with many alterations or improvements, according to the different views and ſkill of their authors. It is needleſs to inſiſt here on their conſtruction. They have been deſcribed in the article Electricity (*Encycl.*); and any perſon well acquainted with its theory, as laid down in the *Supplementary* article Electricity, will be at no loſs to accommodate his own conſtruction to his ſituation and purpoſes.

4
Electrical ſtates of the atmoſphere.

Dr Franklin took the lead, as we have already obſerved,

Thunder.

ferved, in this examination of the electrical ftate of the atmofphere. He feldom found it without giving figns of electricity, and this was generally negative. See *Phil. Tranf.* Vol. XLVIII. p. 358. and 785.

Mr Canton repeated thofe experiments, and found the fame refults; both, however, found that the electricity would frequently change from pofitive to negative, and from negative to pofitive, in very fhort fpaces of time, as different portions of clouds or air paffed the thunder-rod.

5 Cautions to be obferved in this examination by a thunder rod.

We muft here remark, that our acquaintance with the laws of electricity fufficiently informs us, that the electricity of our thunder-rod may frequently be of a different kind from that of the cloud which excites the appearances at our apparatus. We know that air, like glafs, is a non-conductor; and that when it is brought into any ftate of electricity, either by communication, or by mere induction, it will remain in that ftate for fome time, and that it always changes its electricity *per ftratum*. A pofitive cloud, in the higher regions of the atmofphere, will render the air immediately below it negative, and a ftratum below that pofitive. If the thunder rod be in this pofitive ftratum, it will exhibit pofitive electricity; but if the cloud be confiderably nearer, the rod, by being in the adjoining negative ftratum, may fhow a negative electricity which will exceed the pofitive electricity which the diftant pofitive cloud would have induced on its lower end by mere pofition, had the intervening air been away. This excefs of negative electricity muft depend on the degree in which the furrounding ftratum of air has been rendered negative. If this has been the almoft inftantaneous effect of the prefence of the pofitive cloud, it cannot be rendered fo negative as to produce negative electricity in the lower end of the thunder rod. But if the ftratum of air has for fome confiderable time accompanied the pofitive cloud, its negative electricity has been increafing, and fome would remain, even if the cloud were removed. We muft, at all times, confider the thunder rod as affected by *all* the electricity in its neighbourhood. The diftant pofitive cloud would at any rate render the lower end of the rod pofitive, without communication, by merely difplacing the electricity in the rod itfelf, juft as the north pole of a loadftone would make the remote end of a foft iron rod a north pole. In like manner, the negative ftratum of air immediately adjoining to the pofitive cloud would make the lower end of the rod negative, without communication. A pofitive ftratum of air below this would have the contrary effect. The appearances, then, at the end of the rod, muft be the refult of the prevalence of one of thefe above the others; and many intervening circumftances muft be underftood, before we can infer with certainty the ftate of a cloud from the appearances at the lower end of the apparatus. It would, therefore, be a moft inftructive addition to a thunder rod to have an electrofcope at both ends. If they fhew the fame kind of electricity, we may be affured that it is by communication, and is the fame with that of the furrounding ftratum of air: But if they fhew oppofite electricities (which is generally the cafe), then we learn that it is by pofition or induction. We recommend this to the careful attention of the philofopher.

In this way we perfectly explain an appearance which puzzled both of the above-mentioned obfervers. When a fingle low cloud approached the rod, the electrofcope would fhew pofitive electricity, but negative when the cloud was in the zenith, and pofitive again when it had paffed by. We alfo learn from this the caufe of Dr Franklin's difappointment in his expectations of very remarkable phenomena by means of his kite. He imagined that it would be vaftly fuperior to the apparatus which he had recommended to the philofophers of Europe. But the ftring of the kite, traverfing feveral ftrata in different ftates of electricity, ferved as a conductor between them, and he could only obtain the fuperplus; which might be nothing, even when the clouds were ftrongly electrified.

The moft copious and curious obfervations on the electrical ftate of the atmofphere are thofe by Profeffor Beccaria of Turin. He had connected the tops of feveral fteeples of the city by infulated wires. He did the fame thing at a monaftery on a high hill in the neighbourhood. Each of thefe collected the electricity of a feparate ftratum of confiderable extent. He frequently found thefe two ftrata in oppofite ftates of ftrong electricity.

6 Beccaria's general laws of atmofpheric electricity.

The following general obfervations are made out from a comparifon of a vaft variety of more particular ones made in different places:

1. The air is almoft always electrical, efpecially in the day time and dry weather; and the electricity is generally pofitive. It does not become negative, unlefs by winds from places where it rains, fnows, or is foggy.

2. The moifture of the air is the conftant conductor of its electricity in clear weather.

3. When dark or wet weather clears up, the electricity is always negative. If it has been very moift, and dries very faft, the electricity is very intenfe, and diminifhes when the air attains its greateft drynefs; and may continue long ftationary, by a fupply of air in a drying ftate from diftant places.

4. If, while the fky overcafts in the zenith, only a high cloud is formed, without any fecondary clouds under it, and if this cloud is not the extenfion of another which rains in fome remote place, the electricity (if any) is always pofitive.

5. If the clouds, while gathering, are fhaped like locks of wool, and are in a ftate of motion among each other; or if the general cloud is forming far aloft, and ftretches down like defcending fmoke, a frequent pofitive electricity prevails, more intenfe as the changes in the atmofphere are quicker; and its intenfity predicts the great quantity of fnow or rain which is to follow.

6. When an extenfive, thin, level cloud forms, and darkens the fky, we have ftrong pofitive electricity.

7. Low thick fogs, rifing into dry air, carry up fo much electricity as to produce fparks at the apparatus. If the fog continues round the apparatus without rifing, the electricity fails.

8. When, in clear weather, a cloud paffes over the apparatus, low and tardy in its progrefs, and far from any other, the pofitive electricity gradually diminifhes, and returns when the cloud has gone over.

9. When many white clouds gather over head, continually uniting with and parting from each other, and thus form a body of great extent, the pofitive electricity increafes.

10. In

10. In the morning, when the hygrometer indicates dryneſs equal to that of the preceding day, poſitive electricity obtains, even before ſunriſe.

11. As the ſun gets up, this electricity increaſes; more remarkably if the dryneſs increaſes. It diminiſhes in the evening.

12. The mid-day electricity, of days equally dry, is proportional to the heat.

13. Winds always leſſen the electricity of a clear day, eſpecially if damp; therefore they do not electrify the air by friction on ſolid bodies.

14. In cold ſeaſons, with a clear ſky and little wind, a conſiderable electricity ariſes after ſunſet, at dew falling.

The ſame happens in temperate and warm weather.

If, in the ſame circumſtances, the general dryneſs of the air is leſs, the electricity is alſo leſs.

15. The electricity of dew, like that of rain, depends on its quantity. This electricity of dew may be imitated by electrifying the air of a cloſe room (not too dry), and filling a bottle with very cold water, and ſetting it in the upper part of the room. As the damp condenſes on its ſides, an electrometer will ſhew very vivid electricity.

Such a collection of obſervations, to be fit for inference, requires very nice diſcrimination. It is frequently difficult to diſcover electricity in damp air, though it is then generally ſtrongeſt; becauſe the inſulation of the apparatus is hurt by the dampneſs. To make the obſervation with accuracy, requires a portable apparatus, whoſe inſulation can be made good at all times. With ſuch apparatus we ſhall never miſs obſerving electricity in fogs, or during ſnow.

There is a very curious phenomenon, which may be frequently obſerved in Edinburgh, and no doubt in other towns ſimilarly ſituated. In a clear day of the month of May, an eaſterly wind frequently brings a fog with it, which advances from the ſea in a denſe body; and when it comes up the High-ſtreet, it chills the body exceedingly, while it does not greatly affect the thermometer. Immediately before its gaining the ſtreet, one feels like a tickling on the face, as if a cobweb had fallen on it, and naturally puts up his hand, and rubs the face. We have never found this to fail, and have often been amuſed with ſeeing every perſon rubbing his face in his turn. The writer of this article has obſerved the ſame thing at St Peterſburgh, in a ſummer's evening, when a low fog came on about ten o'clock.

7

The general appearances of a thunder ſtorm are nearly as follow:

For the moſt part the wind is gentle, or it is calm. A low denſe cloud begins in a place previouſly clear: this increaſes faſt in ſize; but this is only upwards, and in an arched form, like great bags of cotton. The lower ſurface of the cloud is commonly level, as if it reſted on a glaſs plane.

Soon after appear numberleſs ſmall ragged clouds, like flakes of cotton teazled out. Theſe are moving about in various uncertain directions, and continually changing their ragged ſhape. This change, however, is generally by augmentation. Whatever occaſions the precipitation of the diſſolved water ſeems to gain ground. As theſe clouds move about, they approach each other, and then ſtretch out their ragged arms towards each other. This is not by an augmentation, but by a real bending of theſe tatters towards the other cloud. They ſeldom come into contact; but after coming very near in ſome parts, they as plainly recede, either in whole, or by bending their arms away from each other.

But during this confuſed motion, the whole maſs of ſmall clouds approaches the great one above it; and when near it, the clouds of the lower maſs frequently coaleſce with each other before they finally coaleſce with the upper cloud: But as frequently the upper cloud increaſes without them. Its lower ſurface, from being level and ſmooth, now becomes ragged, and its tatters ſtretch down towards the others, and long arms are extended towards the ground. The heavens now darken apace, the whole maſs ſinks down; wind ariſes, and frequently ſhifts in ſqualls; ſmall clouds are now moving ſwiftly in various directions; lightning now darts from cloud to cloud. A ſpark is ſometimes ſeen coexiſtent through a vaſt horizontal extent, of a crooked ſhape, and of different brilliancy in its different parts. Lightning ſtrikes between the clouds and the earth—frequently in two places at once. A continuation of theſe ſnaps rarifies the cloud; and in time it diſſipates. This is accompanied by heavy rain or hail; and then the upper part of the clouds is high and thin.

During this progreſs of the ſtorm, the thunder rod is ſtrongly electrified; chiefly when the principal cloud is over head. The ſtate of the electricity frequently changes from poſitive to negative—almoſt every flaſh, however diſtant, occaſions a ſudden ſtart of the electroſcope, and then a change of the electricity. When the cloud is more uniform, the electricity is ſo too. 8

Sources of atmoſpheric electricity.

The queſtion now is, In what manner does the air acquire this electricity? How come its different parts to be in different ſtates, and to retain this difference for a length of time? and how is the electric equilibrium reſtored with that rapidity, and to that extent, that we obſerve in a thunder ſtorm? For we know that air is a very imperfect conductor, and tranſmits electricity to ſmall diſtances only, and very ſlowly. We ſhall mention ſeveral circumſtances, which are known facts in electricity, and muſt frequently concur, at leaſt, with the other cauſes of this grand phenomenon.

Air is rendered electrical in a great variety of ways.

1. All operations which excite electricity in other bodies have the ſame effect on air. It is electrified by friction. When blown on any body, ſuch as glaſs, &c. that body exhibits electricity by a ſenſible electroſcope. We therefore conclude that the air has acquired the oppoſite electricity from this rubber. A glaſs veſſel, exhauſted of air, and broken in the dark, gives a loud crack, and a very ſenſible flaſh of light. An air-gun, diſcharged (without a ball) in the dark, does the ſame. Blowing on an electric with a pair of bellows never fails to excite it. In ſhort, the facts to this purpoſe are numberleſs.

2. Electricity is produced by a number of chemical operations, which are continually going on. The melting and freezing of electric bodies in contact with each other, ſuch as chocolate in its moulds, wax-candles in their moulds, ſealing-wax, &c. Nay, it is highly probable that any body, in paſſing from its fluid to its ſolid form, or the contrary, is electrical. This is the caſe when a ſolution of Glauber's ſalt, or of nitre, in water, is made to cryſtallize all at once by agitation.

The

Thunder.

The ſolution of bodies in their menſtrua is, in like manner, productive of electricity in many caſes. Thus iron or chalk, while diſſolving in the ſulphuric acid, produce negative electricity in the mixture, and poſitive in the electric vapours which ariſe from them.

A moſt copious ſource of electricity is the converſion of water into elaſtic ſteam by violent heats. When this is done in a proper apparatus, the electricity of the liquid is negative, and the vapour is poſitive. But if this be accompanied by a decompoſition of the water, the liquid is ſometimes ſtrongly negative. Thus, when water evaporates ſuddenly from a red hot ſilver cup, the cup is ſtrongly negative; but if from clean red hot iron, ſo that the iron is calcined, and inflammable air produced, the iron is poſitive. If the decompoſition of the water is ſufficiently copious to do more than compenſate for the negative electricity produced by the mere expanſion of the water into ſteam, the electricity is poſitive; but not otherwiſe. Water expanded from a piece of red hot coal always gives negative electricity, and this frequently very ſtrong. Theſe experiments ſhould always be made in metalline veſſels. If made in glaſs veſſels, the glaſs takes a charge, which expends the produced electricity, and remains nearly neutral, ſo that the production of electricity is not obſerved. Theſe facts are to be found among many experiments of Mr Sauſſure. But there is here a very wide field of new inquiry, which cannot fail of being very inſtructive, and particularly in the preſent queſtion. We ſee ſome of the effects very diſtinctly in ſeveral phenomena of thunder and lightning. Thus, the great eruptions of Ætna and Veſuvius are always accompanied by forked lightnings, which are ſeen darting among the volumes of emitted ſmoke and ſteam. Here is a very copious converſion of water into elaſtic ſteam; and here alſo it is moſt reaſonable to expect a copious decompoſition of water, by the iron and coally matters, which are expoſed to the joint action of fire and water. Theſe two electricities will be oppoſite; or when not oppoſite, will not be equal: in either of which caſes, we have vaſt maſſes of ſteam in ſtates fit for flaſhing into each other.

A fact more to our purpoſe is, that if a ſilk or linen cloth, of a downy texture, be moiſtened or damped, and hung before a clear fire to dry, the fibres briſtle up, and on bringing the finger, or a metal knob, near them, they are plainly attracted by it. We found them negatively electric. This ſhews that the ſimple ſolution of water in air produces electricity. And this is the chief operation in Nature connected with the ſtate of the atmoſphere. It is thus that the watery vapours from all bodies, and particularly the copious exſudation of plants, diſappear in our atmoſphere. There can be no doubt but that the oppoſite electricity will be produced by the precipitation of this vapour; that is, by the formation of clouds in clear air. When damp, but clear air in one veſſel expands into an adjoining veſſel, from which the air has been exhauſted, a cloud appears in both, and a delicate electrometer is affected in both veſſels; but our apparatus was not fitted for aſcertaining the kind of electricity produced. Here then is another unexplored field of experiment. We got two veſſels made, having diaphragms of thin ſilk. Theſe were damped, and ſet into two tubs of water, of very different temperatures. Dry air was then blown through them, and came from their ſpouts ſaturated with water. The ſpouts were turned toward each other. Being of very different temperatures, the ſtreams produced a cloud upon mixing together, and a ſtrong negative electricity was produced. We even found that an electrometer, placed in a veſſel filled with condenſed air, was affected when this air was allowed to ruſh out by a large hole.

Laſtly, we know that the tourmaline, and many of the columnar cryſtals, are rendered electrical by merely heating and cooling. Nay, Mr Canton found that dry air became negative by heating, and poſitive by cooling, even when it was not permitted to expand or contract.

When water is precipitated, and forms a cloud, it is reaſonable to expect that it will have the electricity of the air from which it is precipitated. This may be various, but in general negative: For the heat by which the air was enabled to diſſolve the water made it negative; and much more the friction on the ſurface of the earth. But as heat cauſed it to diſſolve the water, cold will make it precipitate it; and we ſhould therefore expect that the air will be in the ſtate in which it was when it took up the water. But if it be cooled ſo faſt as to precipitate it in the form of rain, or ſnow, or hail, we may expect poſitive electricity. Accordingly, in ſummer, hail ſhowers always ſhew ſtrong poſitive electricity; ſo does ſnow when falling dry.

Here, then, are copious ſources of atmoſpheric electricity. The mere expanſion and condenſation of the air, and ſtill more the ſolution and precipitation of watery vapours in it, are perhaps ſufficient to account for all the inequality of electric ſtate that we obſerve in the atmoſphere.

9 Strata of the atmoſphere in diff[erent] ſtates of electri[city] and ar[e] tranſp[a]rent.

The maſſes of air thus differently conſtituted are evidently diſpoſed in ſtrata. The clouds are ſeen to be ſo. Theſe clouds are not the ſtrata, but the boundaries of ſtrata; which, from the very nature of things, are in different ſtates with reſpect to the ſuſception or precipitation of water. When two ſuch ſtrata are thus adjoining, they will ſlowly act on each other's temperature, and by mixing will form a thin ſtratum of cloud along their mutual confines. If the one ſtratum has any motion relative to the other, and be in the ſmalleſt degree diſturbed, they will mix to a greater depth in each; and this mixture will not be perfectly uniform. The extreme mobility of air will greatly increaſe this jumble of the adjoining parts of the two ſtrata, and will give the cloud a greater thickneſs. If the jumble has been very great, ſo as to puſh one of them through the other, we ſhall have great towering clouds, perhaps pervading the whole thickneſs of the ſtratum of air. We take theſe clouds to be like great foggy bladders, ſuperficially opaque where they have come into contact with the ſurrounding ſtratum of air, but tranſparent within.

When the wind, or ſtratum in motion, does not puſh all the quieſcent air before it, it generally gets over it, and then flows along its upper ſide, and, by a partial mixing, produces a fleecy cloud, as already deſcribed. We may obſerve here, by the way, that the motion of thoſe fleecy clouds is by no means a juſt indication of the motion of the ſtratum; it is nearly the motion compoſed of the half of the motions of the two.

1[0] Theſe [ſtra]ta ha[ve] ſtrata clouds interpoſ[ed]

This is in all probability the ſtate of the atmoſphere, conſiſting of ſtrata of clear air many hundred yards thick, under.

thick, ſeparated from each other by thin fleeces of clouds, which have been produced by the mixture of the two adjoining ſtrata. This is no fancy; for we actually ſee the ſky ſeparated by ſtrata of clouds at a great diſtance from each other. And we ſee that theſe ſtrata maintain their ſituations, without farther admixture, for a long time, the bounding clouds continuing all the while to move in different directions. In the year 1759, during the ſiege of Quebec, a hard gale blew one day from the weſtward, which made it almoſt impracticable to ſend a number of proviſion boats to our troops ſtationed above the town. While the men were tugging hard at the oars againſt the wind, and hardly advancing, though the tide of flood favoured them, the French threw ſome bombs to deſtroy the boats. One of theſe burſt in the air, near the top of its flight, which was about a quarter of a mile high. The round ball of ſmoke produced by the exploſion remained in the ſame ſpot for above ſeven minutes, and diſappeared by gradual diffuſion. The lower air was moving to the eaſtward at leaſt 30 feet per ſecond.

In 1783, when a great fleet rendezvouſed in Leith Roads, the ſhips were detained by an eaſterly wind, which had blown for ſix weeks without intermiſſion. The ſky was generally clear; ſometimes there was a thin fleece of clouds at a great height, moving much more ſlowly in the ſame direction with the wind below. During the laſt eight days, the upper current was from the weſtward, as appeared by the motion of the upper clouds. High towering clouds came down the river, with a little rain; the ſtrata were jumbled, and the whole atmoſphere grew hazy and uniform: then came thunder, and heavy rain, and the wind below ſhifted to the weſtward.

Thus it is ſufficiently evinced, that the atmoſphere frequently conſiſts of ſuch ſtrata, well diſtinguiſhed from each other: their appearance and progreſs leave us no room to doubt but that they come from different quarters, and had been taken up or formed at different places, and in different circumſtances, and therefore differing in reſpect of their electrical ſtates.

1 lec- uili- is d lowly eral.

The conſequence of their continuing long together would be a gradual but ſlow progreſs of their electricity to a ſtate of equilibrium. The air is perhaps never in a perfectly dry ſtate, and its moiſture will cauſe the electricity to diffuſe itſelf gradually. It is not beyond the power of our mathematics to aſcertain the progreſs of this approximation to the electric equilibrium. We ſee ſomething very like it in the curious experiments of Beccaria with mirror plates laid together, and charged by means of a coating on the outer plates. Theſe plates were found to conſiſt of alternate ſtrata of poſitive and negative electricity, which gradually penetrated through the plates, and coaleſced till they were reduced to two ſtrata; perhaps in time the electricity would have diſappeared entirely by theſe two alſo coaleſcing. In the ſame manner there would be a ſlow transfuſion of ſenſible electricity through theſe ſtrata without any ſenſible appearances. If any collateral cauſes ſhould make a part more damp than the reſt, there would be a more briſk transference through it, accompanied with faint flaſhes of lambent lightning.

; l and ve tion nder

But thunder requires a rapid communication, and a reſtoration of electric equilibrium in an inſtant, and to a vaſt extent. The means for this are at hand, furniſhed by Nature. The ſtrata of charged air are furniſhed with a coating of cloud. The lower ſtratum is coated on the underſide by the earth.

Thunder.

13 Manner in which this is effected by a coating of cloud.

When a jumble is made in any of the ſtrata, a precipitation of vapour muſt generally follow. Thus a conductor is brought between the electrical coatings. This will quickly enlarge, as we ſee that in our little imitations the knobs of our conductors inſtantaneouſly arrange any particles of duſt which chance to lie in the way, in ſuch a manner as to complete the line of conduct, and occaſion a ſpark to fly at a much greater diſtance than it would have leaped if no duſt had been interpoſed. We have often procured a diſcharge between two knobs which were too far aſunder, by merely breathing the damp air between them. In this manner the interpoſed cloud immediately attracts other clouds, grows ragged by the paſſage of electricity through clear air, where it cauſes a precipitation by altering the natural equilibrium of its electricity; for a certain quantity of electricity may be neceſſary for air's holding a certain quantity of vapour. Accordingly we ſee in a thunder ſtorm that ſmall clouds continually and ſuddenly form in parts formerly clear. Whatever cauſes thunder, does in fact promote this precipitation.

Theſe clouds have the electricity of the ſurrounding air, and muſt communicate it to others in an oppoſite ſtate, and within reach. They muſt approach them, and muſt afterwards recede from them, or from any that are in the ſame ſtate of electricity with themſelves. Hence their ragged forms, and the ſimilar form of the under ſurface of the great cloud; hence their continual and capricious ſhifting from place to place: they are carriers, which give and take between the other clouds, and they may become ſtepping ſtones for the general diſcharge.

If a ſmall cloud form a communication with the ground, and the great cloud be poſitive or negative, we muſt have a complete diſcharge, and all the electrical phenomena, with great violence; for this coating of vapour is abundantly complete for the purpoſe. It conſiſts of ſmall veſicles, which are ſufficiently near each other for diſcharging the whole air that is in their interſtices. A phial coated with amalgam is by no means fully coated. If we hold it between the eye and the light, we ſhall ſee that it is only covered with a number of detached points of amalgam, which looks like a cobweb. Yet this glaſs is almoſt completely diſcharged by a ſingle ſpark, the reſiduum being hardly perceptible.

14 The diſcharge is commonly between the clouds

The general ſcene of thunder is the heavens; and it is by no means a frequent caſe that a diſcharge is made into the earth. The air intervening between the earth and the loweſt coating is commonly very much confuſed in conſequence of the hills and dales, which, by altering the currents of the winds, toſs up the inferior parts, and mix them with thoſe above. This generally keeps the earth pretty much in the ſame electrical ſtate as the loweſt ſtratum of the clouds.

15 Which are horizontally diſtant.

Nor are the great thunder ſtorms in general inſtances of the reſtoration of equilibrium between two ſtrata immediately incumbent on each other. They ſeem, for the moſt part, to be ſtrokes between two parcels of air which are horizontally diſtant. This, however, we do not affirm with great confidence. Our chief reaſon for thinking ſo is, that in theſe great ſtorms the ſpark or ſhaft of forked lightning is directed horizontally, and

ſometimes

Thunder.

16 Particular account of forked lightning, and explanation of the long continued and rumbling noise of thunder.

sometimes seen at once through an extent of several miles.

The nature of this spark has not, we think, been properly considered. It is simply compared to a long electrical spark, which we conceive to be drawn through pure air, and is considered as marking the actual transference of electricity from one end to the other. But this we doubt very much. We are certain of having observed shafts of lightning at one and the same instant stretching horizontally, though with many capricious zigzags and lateral sputterings, at least five miles. We cannot conceive this to have been the striking distance, because the greatest vertical distance of the strata is not the half of this. We rather think that it is a simultaneous range of discharges, each accompanied with light, differently bright according to the electrical capacity of the cloud into which it is made; and if there is a real transference of electric matter on this occasion (which we do not affirm), it is only of a small quantity from one cloud to the next adjoining. This we think confirmed by the sound of thunder. It is not a snap, incomparably louder than our loudest snap from coated glass; but a long continued, rumbling, and *very unequable* noise. There is no doubt but that this snap was almost simultaneous through the whole extent of the spark; but its different parts are conveyed to our ear in time, and are therefore heard by us in succession; and it is not an uniform roar, but a rumbling noise, unequally loud, according as the different parts of the snap are indeed differently loud. We should hear a noise of the same kind if we stood at one end of a long line of soldiers, who discharged their musquets (differently loaded) in the same instant. When any part of the spark is very near us, and is not very diffuse, the snap begins with great smartness, and continues for some time, not unlike the violent tearing of a piece of strong silk; after which it becomes more and more mellow as it comes from a greater distance. We do not, however, affirm, that the whole extensive spark and snap are co-existent or simultaneous. The cloud is, in all probability, but an indifferent conductor, and even a sensible time may elapse during the propagation of the spark to a great distance. Beccaria observed this in a line of 250 feet of chain, lying loosely on the ground, and consisting of near 6000 links. He thought that it employed a full second; but when the chain was gently stretched, the communication seemed instantaneous.

17 Observations on the electric spark.

We cannot help thinking that even the electrical snap between two metal knobs is of the same kind. Not a quantity of luminous matter which issues from the one and goes to the other, but a light that is excited or produced in different material interjacent particles of air or other interposed matter. The angular and sputtering form is quite incompatible with the motion of a simple luminous point. Nay, our chemical knowledge here comes in aid, and obliges us to speculate about the manner in which this light is produced. Whence does it come? It may be produced by two knobs of ice. We know that water consists of vital and inflammable air, which have already emitted the light which made an ingredient of their composition. The spark therefore does not come from the ice. Is it then from the air? If so, perhaps water is produced, or rather something else, for there is not always inflammable air at hand to compose water. Yet the transference of electricity has decomposed the air, or has robbed it of part of its light. The remainder may not be water; but it is no longer air. Is not this confirmed by the peculiar smell which always accompanies electric sparks? and the peculiar taste, not unlike the taste felt on the tongue when it is touched by the zinc in the experiments on Galvinism? Even the fine pencil of light which flows from a point positively electrified, appears through a magnifying glass to consist, not of luminous lines, but of lines of luminous points. And these points are of different brilliancy and different colour, both of which are incessantly changing. And be it farther observed, that these lines are curves, diverging from each other, and convex to the axis. This circumstance indicates a mutual repulsion, arising, in all probability, from the expansion of the air. And, lastly, no spark nor light of any kind can be obtained in a space perfectly void of air.

All these circumstances concur in explaining the nature of the shaft of forked lightning. It is a series of appearances excited in the intervening medium, and which produce some chemical change in it. Thunder, when it strikes a house, always leaves a peculiar smell. Inflammable air has also a peculiar and very disagreeable smell. The smell produced by electricity greatly resembles the smell produced by striking two pieces of quartz together.

18 Deluc's [...]tion of thunde[...] probab[...]

Mr Deluc supposes that the electrical spark, as it is exhibited in thunder, is always accompanied by the decomposition of air now so familiarly known, and that this is the origin of the deluge of rain which commonly finishes the storm. But this is not in the smallest degree probable. The decomposition extends surely no farther than where the light is separated; and we should no more expect a deluge of rain, even if we had inflammable air ready at hand, than we expect drops of water in our electrical experiments. Something different from water follows this decomposition, total or partial, of the vital air; and the water which we do observe to accompany thunder, is no more than what we should expect from the copious precipitation of water in a cloudy form. Mr Saussure's observations assure us that the particles of a cloud are vesicles. Indeed no person who has looked narrowly at a fog, or has observed how large the particles are of the cloud which forms in a receiver when we suddenly diminish the density of the air, and who observes how slowly these particles descend, can doubt of their being hollow vesicles. We cannot perhaps explain their formation; but there they are. We can hardly conceive them receiving the commotion which accompanied the snap without collapsing by the agitation. Perhaps the very cessation of their electricity may produce this effect. They will therefore no longer float in the air, but fall, and unite, and come to the ground in rain. We may expect this rain to be copious, for it is the produce of two strata of clouds. It greatly contributes to the putting an end to the storm, by passing through the strata, and helping to restore the equilibrium.

19 Why a[...] how th[...] der ma[...] continu[...] some ti[...]

One may at first expect that a single clap of thunder will restore the equilibrium of any extent of clouds, and we require an explanation of their frequent repetition before this is accomplished. This is not difficult, and the fact is a confirmation of the above theory, which is considerably different from the generally received notions nder.

tions of the ſubject. We conſider the ſtratum of clear air as the charged electric; poſitive on one ſide, and negative on the other, and coated with conducting clouds. When the diſcharge is made, the ſtate of electricity is indeed changed through the whole ſtratum, but the equilibrium is by no means completed. The ſtratum is perhaps a quarter of a mile in thickneſs. The diſcharge does not immediately affect all this: but does it ſuperficially, leaving the reſt unbalanced. It is like the reſiduum which is left in a Leyden phial when the diſcharge has been made by means of a ſpark drawn at a diſtance. It is ſtill more like the reſiduum of the diſcharge of a Leyden phial that is coated only in patches on one ſide. Each of theſe patches diſcharges what is immediately under it and round it to a certain ſmall diſtance, but leaves a part beyond this ſtill charged. This redundant electricity gradually diffuſes itſelf into the ſpaces juſt now diſcharged; and, after ſome conſiderable time has elapſed, another diſcharge may be made. In like manner, the electricity remaining in the interior of the ſtratum diffuſes itſelf, comes within the action of the coating, and may be again diſcharged by a clap of thunder. We have a ſtill better parallel to this in Beccaria's experiments with two or more plates of glaſs laid together. After the firſt diſcharge, the internal ſurfaces will exhibit certain electricity. Lay the plates together, and, after ſome time, the electricity of the inner ſurfaces will be different, and another diſcharge may be obtained.

Magnetiſm affords the beſt illuſtration of this. If a magnet be brought near a piece of ſoft iron, lying below a paper on which iron filings are lightly ſtrewed, it will inſtantly induce a north pole on one end and a ſouth pole on the other; and this will be diſtinctly obſerved by the way in which theſe filings will arrange themſelves. But if, inſtead of ſoft iron we place a bar of hard tempered ſteel, the ſouth pole will be but a ſmall matter removed from the north pole; but by continuing the magnet long in the ſame place, the diſtribution of magnetiſm in the piece of hard ſteel will gradually advance along the bar, and after a long time the neutral point will be almoſt in the middle of the bar, and the ſouth pole will be at the farther end. See MAGNETISM, in this *Suppl.*

20 t thunſtrokes RENING OKES

We ſaid that the clouds were the uſual ſcenes of the violent electric phenomena. We imagine that the greateſt part of the thunder ſtrokes which have been felt have been of the kind which Lord Mahon, now Lord Stanhope, calls the returning ſtroke. If two clouds A and B are incumbent over the plain *a* and *b*; and if A be poſitive and B negative, the earth will be maintained in a negative ſtate at *a*, and a poſitive ſtate at *b*. If the diſcharge be now made between the clouds A and B, the electricity muſt inſtantly ruſh up through a conductor at *a*, and down through one at *b*, and each place will have a ſtroke. The ſame thing will happen if the negative cloud B is above the poſitive cloud A, but not in ſo great a degree; for the negative electricity at *a* will now be much leſs than in the other caſe, becauſe it is induced only by the prevalence of the poſitive cloud A over the more remote negative cloud B.

This returning ſtroke explains, much better than we can by any direct ſtroke, the capricious effects of thunder. A perſon at Vienna received a terrible ſhock by having his hand on a thunder-rod during a violent exploſion which he ſaw above three miles diſtant. Sparks are obſerved at thunder-rods at every the moſt diſtant flaſh of lightning.

Thunder.

21 Beccaria's theory of thunder not juſt.

Beccaria has a different theory of thunder. He imagines that the different parts of the earth are in different ſtates of electricity, and that the clouds are the reſtoring conductors. But this does not accord with what we know of electricity. The earth is ſo good a conductor, that Dr Watſon could not obſerve any time loſt in communicating the electricity to the diſtance of more than four miles. It is very true, that the earth is almoſt always in a ſtate of very unequal, and even oppoſite, electricity in its different parts; but this ariſes from the variety of clouds ſtrongly electrified in the oppoſite way. This induces electricity, or diſturbs the natural uniform diffuſion of electricity, juſt as the bringing magnets or loadſtones into the neighbourhood of a piece of iron, without touching it, renders it magnetical in its different parts. While they continue in their places, the piece of iron will be magnetical, and differently ſo in its different parts.

Such are the thoughts which occur to us on this ſubject. But we by no means affirm that we have given a full account of the procedure of Nature; we have only pointed out ſeveral neceſſary conſequences of the known laws of electricity, and of its production in the atmoſphere by means of natural operations which are continually going on. Theſe *muſt* operate, and produce an electrical ſtate of the atmoſphere greatly reſembling what we obſerve: and we have ſhewn, from the acknowledged doctrines of electricity, how this want of equilibrium may be removed, and muſt be removed, by the ſame operations of Nature. The equilibrium muſt be reſtored by means of the conducting coating furniſhed by the clouds. But theſe may be the leaſt conſiderable of Nature's reſources; and the ſubject is ſtill an unexplored field, in the examination of which we may hope to make great progreſs, in conſequence of our daily increaſing knowledge of the chemical ſtate of the atmoſphere.

22 Dr Franklin's invention of a guard againſt thunder.

Knowledge is valuable chiefly as it is uſeful. No man ever ſaw the propriety of this apothegm more ſtrongly than Dr Franklin, or more aſſiduouſly adhered to it in the courſe of a long and ſtudious life. However greatly we may admire his ſagacity, penetration, and logical diſcrimination, in the diſcoveries he has made in the ſcience of electricity, and his diſcovery of the identity of electricity and thunder, we muſt acknowledge infinitely greater obligations to him for putting it in our power to ward off the fatal, and formerly inevitable ſtroke, of this awful agent in the hands of Nature.

Dr Franklin conſiders the earth as performing the office of a conductor in reſtoring the electric equilibrium of the atmoſphere, which has been diſturbed by the inceſſant action of the unwearied powers of Nature.

He obſerves that the uſual preference will be given to the beſt conductors. In this reſpect, a metal rod far ſurpaſſes the brick, ſtone, timber, and other materials which compoſe our buildings, eſpecially when they are dry, as is uſually the caſe in the thundery ſeaſon. He therefore adviſes us to place metalline conductors in the way of the atmoſpherical electricity, in thoſe places where it is moſt likely to ſtrike, and to continue them

Thunder.

down to the moist earth, at some depth under the surface. Nay, as it has been found that thunder has not in every instance struck the highest parts of buildings, he advises to raise the metalline conductors to some considerable height above the building, the more certainly to invite the electricity to take this course.

23 Directions for constructing it.

To ensure success, he observes that the electrical shock dissipates water, and even metalline conductors when too small. He therefore advises to make the conductor at least half an inch square, none of that size having ever been destroyed, though smaller have, by the thunder: yet even these had conducted the thunder to the ground with perfect safety to the building.

No part of a conductor must terminate in the building; for the electricity accumulates exceedingly at the remote extremities of all long rods, and tends to fly off with great force, especially if another conductor is near. This aids the accumulation, by acquiring at its upper end an electricity opposite to that of the lower end of the other: and this effect, produced by the influence of a positive cloud, makes the upper and negative end of the lower portion of a divided conductor draw more electricity to the lower end of the upper portion. This redundant electricity, strongly attracted by the negative lower portion, flies off with great violence through the air; or if surrounded with any matter capable of conversion into elastic vapour by heat, bursts it with irresistible force. Thus the thunder, acting on the vane spindle of St Bride's steeple in London, sprung from its lower end to the upper end of an iron window bar, and burst the stone in which it was fixed, by expanding the moisture into steam. In like manner it burst the stone at the lower end of this bar, to make its way to an iron cramp which connected the opposite sides of the steeple; from this it struck to another cramp; and so from cramp to cramp, till it reached the gutter leads of the church, bursting and throwing off the stonework in many places.

All interruptions must therefore be carefully avoided, and the whole must be made as much as possible one continued metal rod.

Farther, Dr Franklin, observing the singular property which sharp points possess of drawing off the electricity in silence, advises us to finish our conductor with a fine point of gilt copper, which cannot be blunted by rust.

24 Is the thunder rod an effectual and safe contrivance?

But as thus raising the conductor, and pointing it, are so many invitations to the thunder to take this course; and as we cannot be certain that the quantity thus invited may not be more than what the rod can conduct with safety—it has appeared to Dr Wilson, and other able electricians, that it will be safer to give abundance of conduct to what may unavoidably visit us, without inviting what might otherwise have gone harmlessly by.

This was attentively considered by Dr Franklin, Dr Watson, Mr Canton, Dr Wilson, and others, met as a committee of the Royal Society, at the desire of the Board of Ordnance, to contrive a conductor for the powder magazine at Purfleet.

We think that the theory of induced electricity, founded on Dr Frankin's discoveries, and confirmed by all the later inventions of the electrophorus, condenser, &c. will decide this question in the most satisfactory manner.

When a cloud positively electrified comes over a building, it renders it negatively electrical in all its parts, if of conducting materials, and even the ground on which it stands. This effect is more remarkably produced if the structure is of a tall and slender shape, like a steeple or a rod. Therefore the external electrical fluid is attracted by the building with greater force than if it had consisted of materials less conductive. A discharge will therefore be made through it in preference to any neighbouring building, because it is more eminently negative. For the same reason, if there are two buildings equal and similar, one of them being a good conductor, and the other being a less perfect one, the perfect conductor, becoming more powerfully negative, the cloud will become more strongly positive over this house than over the other, and the stroke will be made through it.

25 Scientific account of the state of electricity induced on a building by a thunder cloud.

26 And on a thunder rod.

The same thing must obtain in a perfect conductor continued from the top to the foundation of a house, built of worse conducting materials. The conductor becoming more eminently negative than any other part of the building, the electric fluid will be more strongly attracted by it, accumulated in its neighbourhood, and will all be discharged through it, so long as it is able to conduct.

If the building is of great extent, the proximity of one part of the building to the thunder cloud may produce an accumulation of electrical fluid in its neighbourhood, in preference to a more perfect, but remote, conductor. But when the distances from the cloud are not very unequal, the accumulation will always be in the neighbourhood of the perfect conductor; and this will determine the discharge that way. The accumulation in the neighbourhood of the rod will be small indeed, when the rod is small; but then it is dense, and the whole of electric phenomena shew that it is the density, and not the quantity, of accumulation which produces the violent tendency to fly off; it is this alone which makes it impossible to confine electricity in a body which terminates in a sharp point.

For the same reason, bodies of the same materials and shape will increase the accumulation in the adjoining part of the cloud in proportion as they are nearer to it, or more advanced beyond the rest of the building.

And bodies of slender shape, and pointed, will produce this accumulation in their neighbourhood in a still more remarkable degree, and determine the course of the discharge with still greater certainty.

But it is evident that a metallic rod, no higher than the rest of the building, may occasion an accumulation in the adjoining part of a near thunder cloud sufficient to produce a discharge, when the building itself, consisting of imperfect conductors, would not have provoked the discharge at all. It may therefore be doubted whether we have derived any advantage from the conductor.

27 Effect of interruptions in conductors.

To judge properly of this, we must consider houses as they really are, consisting of different materials, in very different shapes and situations; and particularly as having many large pieces of metal in their construction, in various positions with regard to the cloud, the ground, and to each other. Suppose all the rest of the building to be of non-conducting materials. When a positive thunder cloud comes overhead, every piece of metal in the building becomes electrical, without having received any thing as yet from the cloud; that end of each

Thunder.

each which is neareſt the cloud becoming negative, and the remote end poſitive. But, moreover, the electricity of one increaſes the electricity of its neighbour. Then the moſt elevated becomes more ſtrongly attractive at its upper end than it would have been had the others been away; and therefore produces a greater accumulation in the nearer part of the thunder cloud than it would otherwiſe have done, and it will receive a ſpark. By this its lower end becomes more overcharged, and this makes the upper end of the next more undercharged, and the ſpark is communicated to it, and ſo on to the ground; which would not have happened without this ſucceſſion of conductors. Thus it is eaſy to conceive, that the accumulation in the cloud is juſt inſufficient to produce a diſcharge—While things are in this ſtate, juſt ready to ſnap, ſhould a man chance to paſs under a bell wire, or under a luſtre hanging by a chain, his body will immediately augment the poſitive electricity of the lower end of the conductor above him, and thus will augment the negative electricity of its upper end. This again will produce the ſame effect in the conductor above it: and thus each conductor becomes more overcharged at its lower end, and more undercharged at the upper end. Before this, every thing was juſt ready to ſnap. All will now ſtrike at once. The cloud will be diſcharged through the houſe, and the man will be the ſacrifice, the whole diſcharge being made through his body. This needs no demonſtration for any well-informed electrician. Thoſe who have only ſuch a knowledge of the theory as can be gathered from the writings of Prieſtley, Cavallo, and other popular authors, may convince themſelves of the truth of what is here delivered in the following manner.

In dry weather, and the moſt favourable circumſtances for good electrical experiments, let a very large globe, ſmoothly covered with metal, and well inſulated, be as highly electrified as poſſible, without expoſing it to a rapid diſſipation. To enſure this circumſtance (which is important) let it be electrified till it begins to ſputter, and note the ſtate of the electrometer. Diſcharge this electricity, and electrify it to about half of this intenſity. Provide three or four inſulated metal conductors, about three inches long and an inch diameter, terminated by hemiſpheres, and all well poliſhed.

Having electrified the globe, as above directed, bring one of the inſulated conductors ſlowly up to it, and note its diſtance when it receives a ſpark. In doing this, take care that there be no conducting body near the remote end of the inſulated conductor. It will be beſt to puſh it gradually forward by means of a long glaſs rod. Withdraw the conductor, diſcharge its electricity, reſtore the globe to its former electricity, indicated by an electrometer, and repeat this experiment till the greateſt ſtriking diſtance is exactly diſcovered. Now ſet another of the inſulated conductors about half an inch behind the firſt, and puſh them forward together, by a glaſs rod, till a ſpark is obtained. The ſtriking diſtance will be found greater than before. Then repeat this laſt experiment, with this difference, that the two conductors are puſhed forward by taking hold of the remote one. The ſtriking diſtance will be found much greater than before. Laſtly, puſh forward the two conductors, the remote one having a wire communicating with the ground, till they are a ſmall matter *without* the ſtriking diſtance; and, leaving them in this ſituation, take any little conducting body, ſuch as a braſs ball fixed on the end of a glaſs rod, and paſs it briſkly through between the globe and the neareſt conductor, or through between the two conductors, taking care that it touch neither of them in the paſſage. It will be ſeen that, however ſwift the paſſage is made, there will be a diſcharge through all the four bodies. The inference from this is obvious and demonſtrative.

A very remarkable inſtance of this fact was ſeen at the chapel in Tottenham Court Road, London. A man, going into the chapel by the eaſt door, was killed by the thunder, which came down from the little bell-houſe, along the bell-wire, and the rod of the clock pendulum, from the end of which it leaped to ſome iron work above the door, and from thence, from nail to nail, till it reached the man's head.

This interruption of conduct, which is almoſt unavoidable in the conſtruction of any building, is the cauſe of moſt of the accidents that are recorded; for when the ends of thoſe communicating conductors are incloſed in materials of leſs conducting power, the electricity, in making its way to the next in a very denſe ſtate, never fails to explode every thing which can be converted into elaſtic vapour by heat. There is always a ſufficient quantity of moiſture in the ſtone or brickwork for this purpoſe; and moſt vegetable ſubſtances contain moiſture or other expanſible matter. The ſtone, brick, or timber, is burſt, and thrown to a conſiderable diſtance; or if kept together by a weight of wall, the wall is ſhattered. It is worth remarking that although no force whatever ſeems able to prevent this exploſion, the quantity of matter exploded is extremely ſmall; for the ſtones are never thrown to a greater diſtance than they would have been by two or three grains of gunpowder properly confined.

All theſe accidents will be prevented by giving a ſufficient uninterrupted conduct; and it is proper to make uſe of ſuch a conductor, although it may invite many diſcharges which would not otherwiſe happen. So long as the conductor is ſufficient for the purpoſe, there ſeems to be no doubt of the propriety of this maxim. 28

A thunder rod will protect even when it is not able to diſcharge the whole thunder.

But the moſt ſerious objection remains. As we are certain that theſe conductors, whether raiſed above the building or not, will produce diſcharges through them which otherwiſe would not have happened, and as we are quite uncertain whether the quantity contained in a thunder cloud may not greatly exceed what the thunder rod can conduct without being diſſipated in ſmoke, it ſeems very dangerous thus to invite a ſtroke which our conductor may not be able to diſcharge. In particular, it is reaſonable to believe that the ſtrata of electrified clouds which come near the earth loſe much of their electricity by paſſing over the ſharp points of trees, &c. while thoſe which are much higher may retain their electricity undiminiſhed, and paſs on. May it not therefore happen, that our conductor will invite a fatal ſtroke, which would have gone harmleſsly by?

The doubt is natural, and it is important.

Let us ſuppoſe a very extenſive and highly electrified cloud, in a poſitive ſtate, to come within ſuch a diſtance from a building as *juſt not to ſtrike it*, if unprovided with a conductor, but which will moſt certainly ſtrike the ſame building furniſhed with a conductor; and let the electricity be ſo great that the conductor ſhall be diſſipated in ſmoke before even a fmall part of it is difcharged—What will be the fate of the building? We believe that it will be perfectly fafe.

However rapid we may fuppofe that motion by which electricity is communicated, it is ftill motion, and time elapfes during the propagation. The cloud is difcharged, not in a very inftant, but in a very fhort time. Part of the cloud is therefore difcharged, while it explodes the conductor, and the electricity of the remainder is now too weak (by our fuppofition) to ftrike the building no longer furnifhed with a conductor. This muft be the cafe, however large and powerful the cloud may be, and however fmall the conductor.

But fuppofe that the cloud has come fo near as to ftrike the building unprovided with a conductor. Then as much will be difcharged through the building as it can conduct; and if the quantity be too great, the building will be deftroyed: but let a conductor (though infufficient) be added. The difcharge will be made through it as long as it lafts, and the remainder only will be difcharged through the houfe, furely with much lefs danger than before.

The truth of thefe conclufions from theory is fully verified by fact. When the church of Newbury in New England was ftruck by lightning in 1755, a bell wire, no bigger than a knitting needle, conducted the thunder with perfect fafety to the building as far down the fteeple as the wire reached, though the ftroke was fo great that the wire had been exploded, and no part of it remained, but only a mark along the wall occafioned by its fmoke. From the termination of the wire to the ground the fteeple was exceedingly fhattered, and ftones of great weight were thrown out from the foundation (where they were probably moifter) to the diftance of 20 and 30 feet.

Another remarkable inftance happened in the fummer palace at St Peterfburg. A Heyduk and a foldier of a foot regiment were ftanding centinels at the door of the jewel-chamber: the Heyduk, with his fcimitar refting on his arm, was carelefsly leaning on the foldier, who had his mufket fhouldered. Both were ftruck down with lightning; and the foldier was killed, his left leg fcorched, and his fhoes burft. The Heyduk had received no damage, but felt himfelf tripped up, as if a great dog had run againft him. A narrow flip of gold lace, which was fewed along the feam of his jacket and pantaloon breeches, reaching to his fhoes, had been exploded on the left fide. This feems to have been his protection. In all probability, the ftroke came to both along the mufket (or perhaps to the Heyduk along the fcimitar). The Heyduk had a complete, though infufficient, conductor, and was fafe. The foldier had not, and was killed. The pufh felt by the former probably arofe from the explofion of the lace.

It feems therefore plain that metalline conductors are always a protection; that advancing them above the building, increafes their protection; and that pointing them may fometimes enable them to diminifh a ftroke, by difcharging part of the electricity filently.

Dr Franklin having formed all his notions of thunder from his pre-eftablifhed theory, and having feen the principal phenomena fo conformable to it, was naturally led to expect this conformity in cafes which he could not eafily examine precifely by experiment. Accordingly, in his firft differtation, he affirmed that a fine point always difcharges a thunder cloud filently, and at a great diftance. The analogous experiments in artificial electricity are fo beautiful and fo perfpicuous, that this confidence in the protecting power of fine points is not furprifing: and this confidence was rendered almoft complete by a moft fingular cafe which fell under his own obfervation. He was awakened one night by loud cracks in his ftair cafe, as if fome perfon had been lafhing the wainfcoating with a great horfewhip. He thought it fo, and got up in anger to chide the idle fool. On looking out at his chamber door, he faw that the difturbance proceeded from electric explofions at fome interruptions of his conductor. He faw the electricity pafs, fometimes in bright fparks, producing thofe loud thwacks, and fometimes in a long continued ftream of denfe white dazzling light as big as his finger, illuminating the ftair-cafe like funfhine, and making a loud noife like a cutler's wheel. Had the cloud (fays he) retained all this till it came within ftriking diftance, the confequences would have been inconceivably dreadful. Yet not long after this he found that he had been in a miftake; for the houfe of Mr Watt in Philadelphia, furnifhed with a finely pointed conductor, was ftruck by a terrible clap of thunder, and the point of the conductor was melted down about two inches. This is perhaps the only inftance on record of a finely-pointed *conductor* being ftruck. The board room at the powder magazine at Purfleet was indeed ftruck, though provided with a conductor; but the ftroke was through another part of the building. St Peter's church, Cornhill, has been eight times ftruck between 1772 and 1787; while St Michael's, in its neighbourhood, and much higher, has never had a ftroke fince 1772, when it was furnifhed with an excellent pointed conductor by Mr Nairne.

29 A point conductor may fometimes be ftruck.

Dr Franklin having feen the above exception to his rule, and reflected on it, acknowledges that there are cafes where a pointed conductor may be ftruck, viz. when it ferves as a ftepping ftone, to *complete* a canal of conveyance already near completed. A *fmall* cloud may fometimes ferve as a ftepping ftone (like the man coming under a luftre) for the electricity to come out of a great cloud, and difcharge through the pointed conductor. Whenever it comes to the ftriking diftance from the conductor, it will explode at once; whereas the great cloud itfelf muft have come nearer, and had its force gradually diminifhed. It is remarkable that a point, employed in this way in artificial electricity, muft be brought nearer to another body than a ball need be, before it can receive a ftroke. The difference is about one-third of the whole. Nairne found, that a ball nine-tenths of an inch in diameter, exploded at the diftance of nine inches, and a point at fix inches diftance.

We muft alfo obferve that a pointed conductor can have no advantage over a blunt one in the cafe of a returning ftroke; which is perhaps the moft common of any. This depends on another difcharge, which is made perhaps at a great diftance. This was moft diftinctly the cafe in the inftance mentioned fome time ago, of the perfon at Vienna who had a fhock from a thunder rod by an explofion far diftant. This thunder rod was a very fine one, furnifhed with five gilt points.

Still, however, this property of fharp points was greatly over-rated by Dr Franklin, and thofe who took all their

…nder. …o …ank- …er- …the …ation …ured …ctors.

their notions of electricity from the ſimple diſcoveries of his ſagacious mind. Unfortunately Dr Franklin had not cultivated mathematical knowledge; and, ever eager after diſcovery, and ardent in all his purſuits, his wonderful penetration carried him through, and ſeldom allowed him to reſt long on falſe concluſions. He was certainly one of the greateſt *philoſophers:* and a little erudition would perhaps have brought him ſide by ſide with Newton. It was reſerved, however, for Lord C. Cavendiſh and for Æpinus, to ſubject the inveſtigations of Franklin to number and meaſure. By ſtudying what they have written on the ſubject, or even the view which we have given of their theory in the article Electricity *(Suppl.)*, the reader will be fully convinced, that a point has little or no advantage over a ball, with reſpect to a thunder cloud which is brought to the thunder rod by a briſk wind; although when it comes ſlowly up during an almoſt perfect calm, it may diſcharge all that can be diſcharged without a ſnap. The conſtipation in a point is indeed very great, but the quantity conſtipated is moderate; and therefore its action, at any conſiderable diſtance, is but trifling. All this is fully verified by Dr Wilſon's judicious experiments in the Pantheon. He had a prodigious quantity of electrified ſurface ſuſpended there, and made a pointed apparatus come to its ſtriking diſtance with a motion which he could regulate and meaſure. And he found that with the very moderate velocity of twelve feet in a ſecond, he never failed of procuring a very ſmart ſtroke. The experiments made in the uſual way by the partiſans of ſharp points (for it became a matter of indecent party) were numberleſs, and decidedly in their favour. The great and juſt authority of Dr Franklin, who was one of the committee, procured them ſtill more conſideration, or at leaſt hindered people from ſeeing the force of Dr Wilſon's reaſoning. It is ſomewhat ſurpriſing, that Dr Wilſon, a lover of mathematical learning, and a good judge, as appears from his publication of the papers of Mr Robins, did not himſelf ſee the full force of his own experiments. He had not ſurely ſtudied either Æpinus or Cavendiſh. He indeed frequently ſays, that the ſtate of the electricity in a thunder cloud, and in coated glaſs, is exceedingly different; and that the firſt extends its ſenſible influence much farther than the laſt, when both have the ſame quantity of electricity. But he ſeems not to have formed to himſelf any adequate notion of the difference. Had he done this, he would have ſeen that he has diſpoſed his great electrified ſurface very improperly. It ſhould have been collected much nearer his pointed apparatus, that this might, if poſſible, have been within the ſphere of attraction of every part of his artificial cloud. He would then have found reſults, ſome of which would have been much more favourable to his own general opinion, while others would have exhibited the peculiarities of the ſharp point in a more ſhowy manner than any thing we have ſeen.

31 …nder …very …e coat- …afs;

Reaſoning from the true theory of coated glaſs, we ſhall learn that, when the glaſs is exceedingly thin, the accumulation of electricity, or the charge, will be exceedingly great; while the external appearance, or apparent energy, of the electricity may be hardly ſenſible, and will extend to a very ſmall diſtance. Thus, a circular plate of coated glaſs, ſix inches in diameter and one-twentieth thick, when electrified ſo as to make an electrometer diverge 50 degrees, contains about 60 times as much electricity as a braſs plate, of the ſame diameter, electrified to the ſame degree; and theſe two will have the ſame influence on an electrometer placed at a diſtance from them, and will give a ſpark nearly at the ſame diſtance. The ſpark from the coated glaſs will be bright, and will give a ſhock; while that from the braſs plate will be trifling. The cauſe of the equality of influence is, that the poſitive electricity of the one ſide of the coated glaſs is almoſt balanced by the negative electricity of the other ſide, and the unbalanced part is about $\frac{1}{59}$th of the whole. If we now take a braſs plate of $46\frac{1}{2}$ inches in diameter, and electrify it to the ſame degree with the coated glaſs, we ſhall find that it will require the ſame number of turns of the machine to bring it to this ſtate, or to charge the coated glaſs. They contain the ſame quantity of electricity, and the ſpark of both will give the ſame ſhock. But this large plate will have a much wider influence: a perſon coming within ten feet of it will ſee his hair bend towards it, and feel like a cobweb on his face.

It may be farther demonſtrated that the power of a point to abſtract the electricity to a given degree from the large plate, is vaſtly ſmaller than its power to abſtract it to the ſame degree from the coated plate. This is different in the different degrees of the abſtraction, and cannot be expreſſed by any one number. 52 And the influence of ſharp points is trifling.

All theſe conſiderations taken together, ſhew us that the pointed conductor has little advantage over the ball in the circumſtance above mentioned. It has however, an advantage, and therefore ſhould be employed; and in the caſe of a calm, or very gentle progreſs of the thunder cloud, the advantage may be very great.

Thus we think the queſtion decided; and the only remaining conſideration is the quantity of metallic conduct that ſhould be given. Prudence teaches us not to ſpare, eſpecially in very lofty buildings. The conductor on the dome of St Paul's in London conſiſts of four iron ſtraps, each four inches broad and one half an inch thick. This conductor was once made red hot by a thunder ſtroke. No inſtance has been found of a rod one half an inch ſquare being exploded. The accident at Mr Watt's houſe in Philadelphia is curious. The braſs wire which terminated the rod had been ten inches long and one-fourth thick at the baſe, and two one-half inches were melted. It was unable, therefore, to conduct that ſtroke when its diameter was leſs than one-ſixteenth of an inch. 33 An extenſive and ſubſtantial metalline conductor is the chief ſecurity.

We recommend lead or copper in preference to iron. Iron waſtes by ruſt, and by exfoliating retains water, which may be dangerous by its expanſion. A ſtrap of lead, two inches broad and one-fourth thick, ſtapled down to the roof or wall with braſs ſtaples, ſecures us from all riſks from neglect. An iron rod, or one faſtened with iron cramps, requires frequent inſpection, to ſee that nothing has failed or waſted by ruſt. The point or points ſhould ſurely be copper. It would be very proper to connect all the leads of the ridges, gutters, and ſpouts, with the conductor, by ſtraps of lead. This will greatly extend its protection.

A great extent of building is not ſufficiently ſecured by one conductor. And a powder magazine ſhould have ſome erected round it at a diſtance on maſts.

Maxims

Maxims in a Thunder Storm.

Avoid being under trees—but be near them: do not avoid rain. When in a room, avoid the fire-side, which would bring you into the neighbourhood of the higheſt part of the houſe, viz. the ſtack of chimneys. The bell-wire, the grate, the fire irons—are bad neighbours. Nay, the ſoot of the chimney is not a good one, eſpecially if it has ever caked together by burning (A). Go to the middle of the room, and ſit down, if not near a luſtre, or any thing hanging from the ceiling. Avoid mirrors, or gilded mouldings.

Thunder *Bay*, in Lake Huron, lies about half way between Saganna Bay and the N. W. corner of the lake. It is about 9 miles acroſs either way; and is thus called from the thunder frequently heard there. —*Morse.*

Thunder Clouds, in phyſiology, are thoſe clouds which are in a ſtate fit for producing lightning and thunder. See the preceding article.

THURMAN, a townſhip in Waſhington county, New York; taken from Queenſburg, and incorporated in 1792.—*Morse.*

THUS, in ſea-language, a word uſed by the pilot in directing the helmſman or ſteerſman to keep the ſhip in her preſent ſituation when ſailing with a ſcant wind, ſo that ſhe may not approach too near the direction of the wind, which would ſhiver her ſails, nor fall to leeward, and run farther out of her courſe.

TIAGA *Point*, or *Cape*, on the weſt coaſt of New-Mexico, is a rough head land, 8 leagues from the valley of Colima.—*Morse.*

TIAOGU, an ancient Indian town, about 150 miles up the Suſquehannah river.—*ib.*

TIBER *Creek*, a ſmall ſtream which runs ſoutherly through the city of Waſhington, and empties into Potowmac river. Its ſource is 236 feet above the level of the tide in the creek; the waters of which and thoſe of Reedy Branch may be conveyed to the Preſident's houſe, and to the capitol.—*ib.*

TIBERIAS (anc. geog.), the laſt town of Galilee, ſituated on the ſouth ſide of the lake Tiberias; built by Herod the Tetrarch, and called *Tiberias* in honour of the Emperor Tiberius; diſtant 30 ſtadia from Hippus, 60 from Gadara, and 120 from Scythopolis: whence it appears to have been at no great diſtance from where the Jordan runs out of the lake. It is a number of times mentioned by St John the Evangeliſt. Pliny places it on the weſt extremity of the lake, commending the ſalubrity of its hot waters. Jerome ſays, the ancient name was *Chennereth*; which, if true, will account for the name of the lake.

TIBERON, *Cape*, a round black rock on the S. W. part of the ſouthern peninſula of the iſland of St Domingo, and forms the N. W. limit of the bay of Tiberon.—*Morse.*

Tiberon, or *Tiburon*, a bay and village on the S. W. part of the iſland of St Domingo. The bay is formed by the cape of its name on the N. W. and Point Burgau on the S. E. a league and three-fourths apart. The ſtream called a river, falls in at the head of the bay, on the weſtern ſide of the village; which ſtands on the high-road, and, according to its courſe along the ſea-ſhore, 10 leagues ſouth of Cape Dame Marie, 20 from Jeremie, and 32 by the winding of the road from Les Cayes. The cape is in lat. 18 20 30 N. and in long. 76 52 40 W. The exports from Cape Tiberon, from Jan. 1, 1789, to Dec. 31, of the ſame year, were 1000lbs white ſugar—377,800lbs brown ſugar—600,002lbs coffee—13,672lbs cotton—1,088lbs indigo—and ſmall articles to a conſiderable amount. Total value of duties on exportation, 2,465 dollars 76 cents. —*ib.*

Tibron, a fort, near the town or village above mentioned; taken by the French, the 21ſt March, 1795. —*ib.*

TICKLE *Harbour*, on the eaſt coaſt of Newfoundland, fifteen leagues from Bonaventura Port.—*ib.*

Tickle *Me Quickly*, a name given by Britiſh ſeamen to a fine, little, ſandy bay of Terra Firma, on the Iſthmus of Darien, at the N. W. end of a reef of rocks, having good anchorage and ſafe landing. The extremity of the rocks on one ſide, and the Samballas Iſlands (the range of which begins from hence) on the other ſide, guard it from the ſea, and ſo form a very good harbour. It is much frequented by privateers.—*ib.*

TICONDEROGA, in the State of New-York, built by the French in the year 1756, on the north ſide of a peninſula formed by the confluence of the waters iſſuing from Lake George into Lake Champlain. It is now a heap of ruins, and forms an appendage to a farm. Its name ſignifies *Noiſy*, in the Indian language, and was called by the French *Corillor*. Mount Independence, in Addiſon county, Vermont, is about 2 miles S. E. of it, and ſeparated from it by the narrow ſtrait which conveys the waters of Lake George and South river into Lake Champlain. It had all the advantages that art or nature could give it, being defended on 3 ſides by water ſurrounded by rocks, and on half of the fourth by a ſwamp, and where that fails, the French erected a breaſt-work 9 feet high. This was the firſt fortreſs attacked by the Americans during the revolutionary war. The troops under General Abercrombie were defeated here in the year 1758, but it was taken the year following by Gen. Amherſt. It was ſurpriſed by Cols. Allen and Arnold, May 10, 1775, and was retaken by Gen. Burgoyne in July, 1777.—*ib.*

Tierra *Auſtral del Eſpiritu Santo*, called by Bougainville,

(A) In the terrible thunder ſtroke on Leven Houſe in Scotland, the two great ſtreams of electricity had taken the courſe of the vents which had been moſt in uſe, but not to get at the iron work, for it had branched off from the vents, at a great diſtance from the bottom. The chief conductors through the building had been various gilded mouldings, gilded leather hangings, gilded ſcreens, picture frames, and the foil of mirrors. In this progreſs the ſteps have been ſo many, and ſo capricious, that no line of progreſs can be traced, according to any principle. The thunder ſeems to have electrified at once the whole of the leaden roof, and, beſides the two main tracks along the vents, to have afterwards darted at every metal thing in its way. The loweſt point of the track was a leaden water ciſtern; which, however, received no damage; but a thick ſtone wall was burſt through to get at it.

a Auf- el Ef- ritu ito,

ville, *The Archipelago of the Great Cyclades*, and by Capt. Cook, *The New Hebrides*, may be confidered as the eaftern extremity of the vaft Archipelago of *New Guinea*. Thefe iflands are fituated between the latitudes of 14 29 and 20 4 S. and between 169 41 and 170 21 E. long. from Greenwich, and confift of the following iflands, fome of which have received names from the different European navigators, and others retain the names which they bear among the natives; viz. Tierra Auftral del Efpiritu Santo, St Bartholomew, Mallicollo, Pic de l'Etoile, Aurora, Ifle of Lepers, Whitfuntide, Ambrym, Paoon, Shepherds Ifles, Sandwich, Erromango, Immer, Tanna, Erronan, Annatom, Apee, Three Hills, Montagu, Hinchinbrook, and Erromanga. Quiros, who firft difcovered thefe iflands, in 1606, defcribes them, as "richer and more fertile than Spain, and as populous as they are fertile; watered with fine rivers, and producing filver, pearls, nutmegs, mace, pepper, ginger, ebony of the firft quality, wood for the conftruction of veffels, and plants which might be fabricated into fail-cloth and cordages, one fort of which is not unlike the hemp of Europe." The inhabitants of thefe iflands, he defcribes, as of feveral different races of men; black, white, mulatto, tawny, and copper-coloured; a proof, he fuppofes, of their intercourfe with various people. They ufe no fire arms, are employed in no mines, nor have they any of thofe means of deftruction which the genius of Europe has invented. Induftry and policy feem to have made but little progrefs among them: they build neither towns nor fortreffes; acknowledge neither king nor laws, and are divided only into tribes, among which there does not always fubfift a perfect harmony. Their arms are the bow and arrows, the fpear and the dart, all made of wood. Their only covering is a garment round the waift, which reaches to the middle of the thigh. They are cleanly, of a lively and grateful difpofition, capable of friendfhip and inftruction. Their houfes are of wood, covered with palm leaves. They have places of worfhip and burial. They work in ftone, and polifh marble, of which there are many quarries. They make flutes, drums, wooden fpoons, and from the mother of pearl, form chiffels, fciffars, knives, hooks, faws, hatchets, and fmall round plates for necklaces. Their canoes are well built and neatly finifhed. Hogs, goats, cows, buffaloes, and various fowls and fifh, for food are found in abundance on and about thefe iflands. Added to all thefe and many other excellencies thefe iflands are reprefented as having a remarkably falubrious air, which is evinced by the healthy, robuft appearance of the inhabitants, who live to a great age, and yet have no other bed than the earth. Such is the defcription which Quiros gives of thefe iflands in and about which he fpent fome months, and which he reprefents to the king of Spain as "the moft delicious country in the world; the garden of Eden, the inexhauftible fource of glory, riches, and power to Spain." On the north fide of the largeft of thefe iflands, called *Efpiritu Santo*, is a bay, called *San Felipe* and *Sant-Yago*, which, fays Quiros, "penetrates 20 leagues into the country; the inner part is all fafe, and may be entered with fecurity, by night as well as by day. On every fide, in its vicinity, many villages may be diftinguifhed, and if we may judge by the fmoke which rifes by day, and the fires that are feen by night, there are many more in the interior parts." The harbour in this bay, was named by Quiros, *La Vera Cruz*, and is a part of this bay, and large enough to admit 1000 veffels. The anchorage is on an excellent bottom of black fand, in water of different depths, from 6 to 40 fathoms, between two fine rivers.—*ib.*

Tierra del Fuego, || Tillandfia.

TIERRA DEL FUEGO, feveral iflands at the fouthern extremity of America. They take their name from a volcano on the largeft of them. They are all very barren and mountainous; but from what Mr Forfter fays, in his Voyage to the South Sea, the climate does not appear to be fo rigorous and tempeftuous as it is reprefented in Anfon's Voyage. Upon the lower grounds and iflands, that were fheltered by the high mountains, Mr Forfter found feveral forts of trees and plants, and a variety of birds. Among the trees was Winter's bark-tree, and a fpecies of *arbutus*, loaded with red fruit of the fize of fmall cherries, which were very well tafted. In fome places there is alfo plenty of celery. Among the birds was a fpecies of duck, of the fize of a goofe, which ran along the fea with amazing velocity, beating the water with its wings and feet. It had a gray plumage, with a yellow bill and feet, and a few white quill-feathers. At the Falkland Iflands it is called a *loggerhead-duck*. Among the birds are alfo plenty of geefe and falcons. The rocks of fome of the iflands are covered with large mufcle-fhells, the fifh of which is well flavoured. The natives of this country are fhort in their perfons, not exceeding five feet fix inches at moft, their heads large, their faces broad, their cheek bones prominent, and their nofes flat. They have little brown eyes, without life; their hair is black and lank, hanging about their heads in diforder, and befmeared with train-oil. On the chin they have a few ftraggling fhort hairs inftead of a beard. The whole affemblage of their features forms the moft loathfome picture of mifery to which human nature can poffibly be reduced. Thofe which Mr Forfter faw had no other clothing than a fmall piece of feal fkin, which hung from their fhoulders to the middle of their back, being faftened round the neck with a ftring: the reft of their body was perfectly naked. Their natural colour feems to be an olive brown, with a kind of glofs, refembling that of copper; but many of them difguife themfelves with ftreaks of red paint, and fometimes, though feldom, with white. Their whole character is a ftrange compound of ftupidity, indifference, and inactivity. They have no other arms than bows and arrows; and their inftruments for fifhing are a kind of fifh-gigs. They live chiefly on feals flefh, and like the fat oily part moft. There is no appearance of any fubordination among them; and their mode of life approaches nearer to that of brutes than that of any other nation.

TIGNARES, the chief town of the captainfhip of Rio Grande in Brazil.—*Morse.*

TILLANDSIA, the large barren WILD PINE of the Weft Indies; a genus of the monogynia order, belonging to the hexandria clafs of plants. It is called *Caragatua* by Father Plumier, and is a parafitic plant, and ought perhaps, in ftrict propriety, to be denominated an *aquatic:* for although it is fufpended in the air among the branches of lofty trees, to whofe boughs it is faftened by its numerous roots; yet it is not indebted to thofe boughs, like the mifletoe and other parafitic plants, for nourifhment, but merely for fupport; provident Nature having, in a very extraordinary manner, fupplied this with other means to preferve its exiftence:

For

For the leaves, which much resemble those of the pine-apple, but are larger, surround this plant in a circular manner; each leaf being terminated near the stalk with a hollow bucket, which contains about half a pint of water. It is by these numerous small reservoirs of water that the roots, as well as every other part of this plant, are supplied with nourishment without the help of any earth. The flourishing condition of this plant, as well as the great growth of fig-trees, upon barren rocks, shews that water is of greater use to vegetation than earth.

One contrivance of Nature in this vegetable, says Dr Sloane, is truly admirable. The seed is crowned with many long downy threads, not only that it may be carried every where by the wind, but that by those threads, when driven through the boughs, it may be held fast, and stick to the arms and prominent parts of the barks of trees. So soon as it sprouts or germinates, although it be on the under part of a bough, its leaves and stalks rise perpendicular or erect: if they assumed any other direction, the cistern or reservoir just mentioned, made of the hollow leaves, could not hold water, which is necessary to the life and nourishment of the plant. In scarcity of water this reservoir is useful, not to the plant only, but to men, and even to birds and all sorts of insects, which come thither in troops, and seldom go away without refreshment.

To the same purpose, Dampier, in his voyage to Campeachy relates, "that the wild pine has leaves that will hold a pint and an half or quart of rain-water, which refreshes the leaves, and nourishes the roots. When we find these pines, we stick our knives into the leaves, just above the root; and the water gushing out we catch it in our hats, as I myself have frequently done, to my great relief."

TIMÆUS, a Greek historian, the son of Andronicus, who was eminent for his riches and excellent qualities, was born at Tauromenium in Sicily, and flourished in the time of Agathocles. He wrote several books, and among the rest an history of his own country; but they are all lost.

Timæus, a famous Pythagorean philosopher, was born at Locres in Italy, and lived before Plato. There is still extant a small treatise of his on Nature and the Soul of the World, written in the Doric dialect. This treatise, which is to be found in the works of Plato, furnished that great Philosopher with the subject of his treatise intitled *Timæus*.

TIMMISKAMAIN *Lake*, in Lower-Canada, is about 30 miles long and 10 broad, having several small islands. Its waters empty into Utawas river, by a short and narrow channel, 30 miles N. of the N. part of Nepissing lake. The Indians named Timmiscamaings reside round this lake.—*Morse*.

TINICUM, two townships of Pennsylvania; the one in Buck's county, the other in that of Delaware.—*ib.*

TINKER'S *Island*, one of the Elizabeth Islands, on the coast of Massachusetts, off Buzzard's Bay, 8 miles from the main land of Barnstable county. It is the second in magnitude, and the middle one of the 3 largest. It is about 3 miles long from north to south, and about a mile and a half broad from east to west; and between this and Nashawn Island is a channel for sloops and small vessels, as there is also between it and Slocum's Island, about a mile farther to the westward.—*ib.*

TINMOUTH, a township of Nova-Scotia on the eastern coast. It was formerly called Picton, and lies about 40 miles from Truro.—*ib.*

Tinmouth, a township of Vermont, Rutland county, and contains 935 inhabitants.—*ib.*

TINNING, the covering or lining of any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated or *tinned* with thin plates of beaten tin, by a process described under the title Foliating, *Encycl.*

Kettles, sauce-pans, and other kitchen utensils, which are usually made of copper, are tinned by the following process: The surface to be tinned, if of new copper, should first be cleaned or scoured with salt and sulphuric acid (vitriolic acid) diluted with water. This, however, is not always done; some workmen contenting themselves with scouring it with sand perfectly dry, or with scales of iron. Powdered rosin is then strewed over it; and when the vessel or utensil is considerably heated, melted tin is poured into it, and rubbed with flax coiled hard over the surface to be coated. This tin may be either pure, such as that known by the name of *grain-tin*; or a composition consisting of two parts of tin and one of lead. For very obvious reasons, we should certainly prefer the pure tin; but the generality of workmen give the preference to the composition, because the surface coated with it appears more brilliant. The tin is not always put into the vessel in a liquid state; for some workmen strew it in small pieces over the surface to be coated, and then heat the vessel till the tin melt, when they rub it as formerly.

In tinning old vessels which have been tinned before, the process is somewhat different. In these cases, the surface is first scraped with an instrument proper for the purpose, or scoured with the scales of iron, which may be always found in a blacksmith's shop: it is then strewed over with sal ammoniac in powder, instead of rosin, or an infusion of sal ammoniac in stale urine is boiled in it till the urine be evaporated, and it is then tinned with pure tin; the composition of tin and lead being in this case never used. The tin, while liquid, is rubbed into the surface with a piece of sal ammoniac, instead of a bundle of flax. When iron vessels are to be tinned, they are first cleaned with muriatic acid, after which the process is the same as in the tinning of old copper.

In the year 1785, Mr John Poulain of Mortlake, Surry, obtained a patent for the discovery of a new composition for tinning vessels, especially such as are used for culinary purposes. This composition consists of grain-tin one pound, good malleable iron one ounce and a half, platinum one drachm, silver one pennyweight, gold three grains; the whole must be well fused together in a crucible, with one ounce of pounded borax, and two ounces of pounded glass, and then cast in small ingots. The composition, to be fit for use, must be heated and put in a metal mortar, also heated over a fire, and well pounded with a heated metal pestle; when it is well pounded, make an ingot of it, by putting it on the fire in a mould made of iron plate, in which mould the composition must be well stirred and let to cool; then it is fit for use. To apply the composition, first tin the utensil or vessel with grain-tin and sal ammoniac, as is usually done in the common way of tinning; clean well the tinned part of the metal utensil or

vessel,

veſſel, and then apply a coat of the compoſition with ſal ammoniac, as is uſually done in the common way of tinning; and when the compoſition is well ſpread, let it cool; then make it a little red-hot in all its parts, to neal it, and plunge the metal utenſil or veſſel, while yet hot, in cold water; then, with a ſharp ſcraper, ſcrape and rub off the rough or grumous particles of the compoſition applied on the metal utenſil or veſſel, and ſcour it well with ſand. The ſame operation muſt be repeated for every coat of the compoſition that is applied; two coats of the compoſition are quite ſufficient for culinary utenſils or veſſels, and a thin coat of grain tin may be applied over the laſt coat of the compoſition, to ſmooth it. The author adds, that his compoſition may be employed for covering or plating the ſurfaces of all materials made of copper, braſs, iron, and other metals or mixtures of metals, and that it ſhould be applied with a charcoal fire in preference to any other fire. All this may be true, and it may be a very valuable coating to copper; but the ſcarcity, high price, and infuſibility of platinum, muſt for ever prevent it from coming into very general uſe.—We think that even the *Enamelling of Veſſels for the Kitchen* muſt be more common. See that article in this *Supplement*.

The following proceſs is leſs expenſive, whilſt the coating given by it is exceedingly durable, adds ſtrength to the copper veſſel, and ſecures it much longer than the common tinning from the action of acids:

When the veſſel has been prepared and cleaned in the uſual manner, it muſt be roughened on the inſide by being beat on a rough anvil, in order that the tinning may hold better, and be more intimately connected with the copper. The proceſs of tinning muſt then be begun with perfectly pure grained tin, having an addition of ſal ammoniac inſtead of the common colophonium or reſin. Over this tinning, which muſt cover the copper in an even and uniform manner throughout, a ſecond harder coat muſt be applied, as the firſt forms only a kind of medium for connecting the ſecond with the copper. For this ſecond tinning you employ pure grained tin mixed with zinc in the proportion of two to three, which muſt be applied alſo with ſal ammoniac ſmooth and even, ſo that the lower ſtratum may be entirely covered with it. This coating, which, by the addition of the zinc, becomes pretty hard and ſolid, is then to be hammered with a ſmoothing hammer, after it has been properly rubbed and ſcoured with chalk and water; by which means it becomes more ſolid, and acquires a ſmooth compact ſurface.

Veſſels and utenſils may be tinned in this manner on both ſides. In this caſe, after being expoſed to a ſufficient heat, they muſt be dipped in the fluid tin, by which means both ſides will be tinned at the ſame time.

As this tinning is exceedingly durable, and has a beautiful colour, which it always retains, it may be employed for various kinds of metal inſtruments and veſſels which it may be neceſſary to ſecure from ruſt.

TINPLATE, called in Scotland *White-iron*, is a thin plate of iron covered with tin, to which it is united by chemical affinity. See Chemistry, nº 122. *Suppl.*

TINSIGNAL, a rich ſilver mine in the province of Coſta Rica.—*Morse*.

TINTA, a juriſdiction in the empire of Peru; wherein is the famous ſilver mine called Condonoma.—*ib.*

TINTAMARE, a river of Nova-Scotia, which is navigable 3 or 4 miles up for ſmall veſſels.—*ib.*

TINTO, a river of Terra Firma, 20 leagues to the eaſt of Cape Honduras.—*ib.*

TIOGA, a townſhip of Pennſylvania, in Luzerne county.—*ib.*

Tioga, a county of New York, bounded eaſt by Otſego, weſt by Ontario, north by Onondago, and ſouth by the State of Pennſylvania. It contains the towns of Newtown, Union, Chemung, Owego, Norwich, Jerico, and Chenengo, in which are 1,165 electors, according to the State cenſus of 1796. The courts of common pleas and general ſeſſions of the peace for the county are held on the firſt Tueſdays in May, October, and February, in every year, alternately at Chenengo, in the town of Union, and at Newtown Point, in the town of Chemung. Some curious bones have been dug up in this county. About 12 miles from Tioga Point, the bone or horn of an animal was found, 6 feet 9 inches long; 21 inches round, at the long end, and 15 inches at the ſmall end. It is incurvated nearly to an arch of a large circle. By the preſent ſtate of both the ends, much of it muſt have periſhed; probably 2 or 3 feet from each end.—*ib.*

Tioga *Point*, the point of land formed by the confluence of Tioga river with the eaſt branch of Suſquehannah river. It is about 5½ miles ſoutherly from the line which divides New-York State from Pennſylvania, and is about 150 miles N. by W. of Philadelphia, and 20 S. E. of Newtown. The town of Athens ſtands on this point of land.—*ib.*

Tioga *River*, a branch of the Suſquehannah, which riſes in the Alleghany Mountains in about lat. 42, and running eaſtwardly, empties into the Suſquehannah at Tioga Point, in lat. 41 57. It is navigable for boats about 50 miles. There is ſaid to be a practicable communication between the ſouthern branch of the Tioga, and a branch of the Alleghany, the head waters of which are near each other. The Seneca Indians ſay they can walk 4 times in a day from the boatable waters of the Alleghany, to thoſe of the Tioga, at the place now mentioned.—*ib.*

TIOOKEA, an Iſland in the South Pacific Ocean, one of thoſe called George's Iſlands. S. lat. 14 27, W. long. 144 56.—*ib.*

TIPRA, the name of certain mountainous diſtricts to the eaſtward of Bengal, inhabited by a people of very ſingular manners. As every thing which contributes a ſingle fact to the hiſtory of human nature is intereſting to the philoſopher, the reader will be pleaſed with the following account of the religion, laws, and manners of theſe people, taken from the 2d volume of the *Aſiatic Reſearches*.

Though they acknowledge one Creator of the univerſe, to whom they give the name of Pa'tiya'n, they believe that a deity exiſts in every tree, that the ſun and moon are gods, and that whenever they worſhip thoſe ſubordinate divinities Pátiyán is pleaſed. This is very ſimilar to the religious creed of ancient Greece and Rome, differing only with reſpect to creation, which, in the proper ſenſe of the word, the Greeks and Romans ſeem not to have admitted.

If any one of theſe mountaineers, called in the memoir Cucis, put another to death, the chief of the tribe, or other perſons who bear no relation to the deceaſed,

ceased, have no concern in punishing the murderer; but if the murdered person have a brother or other heir, he may take blood for blood; nor has any man whatever a right to prevent or oppose such retaliation.

When a man is detected in the commission of theft or other atrocious offence, the chieftain causes a recompense to be given to the complainant, and reconciles both parties; but the chief himself receives a customary fine, and each party gives a feast of pork or other meat to the people of his respective tribe.

In ancient times, it was not a custom among them to cut off the heads of the women whom they found in the habitations of their enemies; but it happened once that a woman asked another, why she came so late to her business of sowing grain? she answered, that her husband was gone to battle, and that the necessity of preparing food and other things for him had occasioned her delay. This answer was overheard by a man at enmity with her husband; and he was filled with resentment against her, considering, that as she had prepared food for her husband for the purpose of sending him to battle against his tribe, so in general, if women were not to remain at home, their husbands could not be supplied with provision, and consequently could not make war with advantage. From that time it became a constant practice to cut off the heads of the enemy's women, especially if they happen to be pregnant, and therefore confined to their houses: and this barbarity is carried so far, that if a Cuci assail the house of an enemy, and kill a woman with child, so that he may bring two heads, he acquires honour and celebrity in his tribe, as the destroyer of two foes at once.

As to the marriages of this wild nation, when a rich man has made a contract of marriage, he gives four or five head of *gayáls* (the cattle of the mountains) to the father and mother of the bride, whom he carries to his own house: Her parents then kill the *gayáls;* and having prepared fermented liquors and boiled rice with other eatables, invite the father, mother, brethren, and kindred of the bridegroom to a nuptial entertainment. When a man of small property is inclined to marry, and a mutual agreement is made, a similar method is followed in a lower degree; and a man may marry any woman except his own mother. If a married couple live cordially together, and have a son, the wife is fixed and irremoveable; but if they have no son, and especially if they live together on bad terms, the husband may divorce his wife, and marry another woman.

They have no idea of heaven or hell, the reward of good, or the punishment of bad, actions; but they profess a belief, that when a person dies, a certain spirit comes and seizes his soul, which he carries away; and that whatever the spirit promises to give at the instant when the body dies, will be found and enjoyed by the dead; but that if any one should take up the corse and carry it off, he would not find the treasure.

The food of this people consists of elephants, hogs, deer, and other animals; of which if they find the carcases or limbs in the forests, they dry them, and eat them occasionally.

When they have resolved on war, they send spies before hostilities are begun, to learn the stations and strength of the enemy, and the condition of the roads; after which they march in the night, and two or three hours before daylight make a sudden assault with swords, lances, and arrows: if their enemies are compelled to abandon their station, the assailants instantly put to death all the males and females, who are left behind, and strip the houses of all their furniture; but should their adversaries, having gained intelligence of the intended assault, be resolute enough to meet them in battle, and should they find themselves overmatched, they speedily retreat and quietly return to their own habitations. If at any time they see a star very near the moon, they say, "to-night we shall undoubtedly be attacked by some enemy;" and they pass that night under arms with extreme vigilance. They often lie in ambush in a forest near the path, where their foes are used to pass and repass, waiting for the enemy with different sorts of weapons, and killing every man or woman who happens to pass by: in this situation, if a leech, or a worm, or a snake, should bite one of them, he bears the pain in perfect silence; and whoever can bring home the head of an enemy, which he has cut off, is sure to be distinguished and exalted in his nation. When two hostile tribes appear to have equal force in battle, and neither has hopes of putting the other to flight, they make a signal of pacific intentions, and, sending agents reciprocally, soon conclude a treaty; after which they kill several head of *gayáls*, and feast on their flesh, calling on the sun and moon to bear witness of the pacification: but if one side, unable to resist the enemy, be thrown into disorder, the vanquished tribe is considered as tributary to the victors; who every year receive from them a certain number of *gayáls*, wooden dishes, weapons, and other acknowledgments of vassalage. Before they go to battle, they put a quantity of roasted *álus* (esculent roots like potatoes), and paste of rice-flour, into the hollow of bamboos, and add to them a provision of dry rice with some leathern bags full of liquor: then they assemble, and march with such celerity, that in one day they perform a journey ordinarily made by letter-carriers in three or four days, since they have not the trouble and delay of dressing victuals. When they reach the place to be attacked, they surround it in the night, and at early dawn enter it, putting to death both young and old, women and children, except such as they choose to bring away captive: they put the heads, which they cut off, into leathern bags; and if the blood of their enemies be on their hands, they take care not to wash it off. When after this slaughter they take their own food, they thrust a part of what they eat into the mouths of the heads which they have brought away, saying to each of them, "Eat, quench thy thirst, and satisfy thy appetite; as thou hast been slain by my hand, so may thy kinsmen be slain by my kinsmen!" During their journey, they have usually two such meals; and every watch, or two watches, they send intelligence of their proceedings to their families. When any one of them sends word that he has cut off the head of an enemy, the people of his family, whatever be their age or sex, express great delight, making caps and ornaments of red and black ropes; then filling some large vessels with fermented liquors, and decking themselves with all the trinkets they possess, they go forth to meet the conqueror, blowing large shells, and striking plates of metal, with other rude instruments of music. When both parties are met, they show extravagant joy, men and women dancing and singing together; and if a married man has brought an enemy's enemy's head, his wife wears a head dress with gay ornaments, the husband and wife alternately pour fermented liquor into each other's mouths, and she washes his bloody hands with the same liquor which they are drinking. Thus they go revelling, with excessive merriment, to their place of abode; and having piled up the heads of their enemies in the court yard of their chieftain's house, they sing and dance round the pile; after which they kill some *gayáls* and hogs with their spears; and having boiled the flesh, make a feast on it, and drink the fermented liquor. The richer men of this race fasten the heads of their foes on a bamboo, and fix it on the graves of their parents, by which act they acquire great reputation. He who brings back the head of a slaughtered enemy, receives presents from the wealthy of cattle and spirituous liquor; and if any captives are brought alive, it is the prerogative of those chieftains, who were not in the campaign, to strike off the heads of the captives. Their weapons are made by particular tribes; for some of them are unable to fabricate instruments of war.

In regard to their civil institutions; the whole management of their household affairs belongs to the women; while the men are employed in clearing forests, building huts, cultivating land, making war, or hunting game and wild beasts. Five days (they never reckon by months or years) after the birth of a male child, and three days after that of a female, they entertain their family and kinsmen with boiled rice and fermented liquor; and the parents of the child partake of the feast. They begin the ceremony with fixing a pole in the court yard; and then killing a *gayál* or a hog with a lance, they consecrate it to their deity; after which all the party eat the flesh and drink liquor, closing the day with a dance and with songs. If any one among them be so deformed, by nature or by accident, as to be unfit for the propagation of his species, he gives up all thought of keeping house, and begs for his subsistence, like a religious mendicant, from door to door, continually dancing and singing. When such a person goes to the house of a rich and liberal man, the owner of the house usually strings together a number of red and white stones, and fixes one end of the string on a long cane, so that the other end may hang down to the ground; then, paying a kind of superstitious homage to the pebbles, he gives alms to the beggar; after which he kills a *gayál* and a hog, and some other quadrupeds, and invites his tribe to a feast: the giver of such an entertainment acquires extraordinary fame in the nation, and all unite in applauding him with every token of honour and reverence.

When a *Cúcì* dies, all his kinsmen join in killing a hog and a *gayál;* and, having boiled the meat, pour some liquor into the mouth of the deceased, round whose body they twist a piece of cloth by way of shroud: all of them taste the same liquor as an offering to his soul; and this ceremony they repeat at intervals for several days. Then they lay the body on a stage, and kindling a fire under it, pierce it with a spit and dry it; when it is perfectly dried, they cover it with two or three folds of cloth, and, enclosing it in a little case within a chest, bury it under ground. All the fruits and flowers that they gather within a year after the burial they scatter on the grave of the deceased: but some bury their dead in a different manner; covering them first with a shroud, then with a mat of woven reeds, and hanging them on a high tree. Some, when the flesh is decayed, wash the bones, and keep them dry in a bowl, which they open on every sudden emergence; and, fancying themselves at a consultation with the bones, pursue whatever measures they think proper; alleging that they act by the command of their departed parents and kinsmen. A widow is obliged to remain a whole year near the grave of her husband; where her family bring her food: if she die within the year, they mourn for her; if she live, they carry her back to her house, where all her relations are entertained with the usual feast of the *Cúcis.*

If the deceased leave three sons, the eldest and the youngest share all his property; but the middle son takes nothing: if he have no sons, his estate goes to his brothers; and if he have no brothers, it escheats to the chief of the tribe.

TIRESIAS, a famous soothsayer of antiquity, was the son of Everes and the nymph Chariclo. Pherecydes says, that Minerva being accidentally seen by Tiresias, as she was bathing with Chariclo in the fountain of Hippocrene, the goddess was enraged, and declared that he should see nothing more: on which he instantly lost his sight; but afterwards received from the goddess superior endowments. Others say, that Juno struck him stone-blind for deciding a case between Jupiter and her, to her dissatisfaction; for which Jupiter gave him the faculty of divination: He was the most celebrated prophet in the Grecian annals. Ulysses is ordered by Circe to consult him in the shades.

> There seek the Theban bard depriv'd of sight,
> Within irradiate with prophetic light.

But, besides the honour done to him by Homer, Sophocles makes him act a venerable and capital part in his tragedy of Oedipus. Callimachus ascribes to Minerva the gift of his superior endowments; the preeminence of his knowledge is likewise mentioned by Tully in his first book of Divination. And not only Tiresias is celebrated by Diodorus Siculus, but his daughter Daphne, who, like her father, was gifted with a prophetic spirit, and was appointed priestess at Delphos. She wrote many oracles in verse, from whence Homer was reported to have taken several lines, which he interwove in his poems. As she was often seized with a divine fury, she acquired the title of *sibyl,* which signifies "enthusiast." She is the first on whom it was bestowed: in aftertimes this denomination was given to several other females that were supposed to be inspired, and who uttered and wrote their predictions in verse; which verse being sung, their function may be justly said to unite the priesthood with prophecy, poetry, and music.

TISBURY, a small fishing town on the south side of the island of Martha's Vineyard, 9 miles from Chilmark, and 97 from Boston. The township was incorporated in 1671, and contains 1142 inhabitants. It is in Duke's county, Massachusetts, and in 1796 the easterly part was incorporated into a separate township. —*Morse.*

TISCAN, a village of Ouenca, and department of Alansis, in Quito, in South-America, which was entirely destroyed by an earthquake, but the inhabitants escaped, and removed to a safer situation. The marks of this dreadful convulsion of nature are still visible.—*ib.*

TISRI, or Tizri, in chronology, the first Hebrew month of the civil year, and the 7th of the ecclesiastical or sacred year. It answered to part of our September and October.

TITHING-Men, are now a kind of petty constables, elected by parishes, and sworn in their offices in the court-leet, and sometimes by justices of the peace, &c. There is frequently a tithing-man in the same town with a constable, who is, as it were, a deputy to execute the office in the constable's absence; but there are some things which a constable has power to do, that tithing men and head-boroughs cannot intermeddle with. When there is no constable of a parish, his office and the authority of a tithing man seems to be all one under another name.

TITHONUS, in fabulous history, the son of Laomedon king of Troy, and the brother of Priamus; was beloved by Aurora, who carried him to Delos, thence to Ethiopia, and at last to heaven, where she prevailed on the Destinies to bestow upon him the gift of immortality: but forgot to add that of youth, which could only render the present valuable. At length Tithonus grew so old that he was obliged to be rocked to sleep like an infant; when Aurora, not being able to put an end to his misery by death, transformed him into a grasshopper; which renews its youth by casting his skin, and in its chirping retains the loquacity of old age.

TITICACA, an island of S. America, in the South Pacific Ocean, near the coast of Peru.—*Morse.*

Titicaca, or *Chucuito*, a lake of Charcas, in Peru; and is the largest of all the known lakes in S. America. It is of an oval figure, with an inclination from N. W. to S. E. and about 80 leagues in circuit. The water is, in some parts, 70 or 80 fathoms deep. Ten or twelve large, besides a greater number of smaller streams fall into it. The water of this lake, though neither salt nor brackish, is muddy, and has something so nauseous in its taste, as not to be drank. One of the most splendid temples in the empire was erected on an island in this lake, by the Yncas. The Indians, on seeing the violent rapacity of the Spaniards, are thought to have thrown the immense collection of riches in the temple, into this lake. But these valuable effects were thrown into another lake, in the valley of Orcos, 6 leagues S. of Cusco, in water 23 or 24 fathoms deep. Towards the S. part of Titicaca Lake, the banks approach one another, so as to form a kind of bay, terminating in a river, called El Desaguadero, or the drain; and afterwards forms the Lake of Paria, which has no visible outlet. Over the river El Desaguadero still remains the bridge of rushes, invented by Capac-Yupanqui, the fifth Ynca, for transporting his army to the other side, in order to conquer the provinces of Collasuyo. The Desaguadero is here between 80 and 100 yards in breadth, flowing with a very impetuous current, under a smooth, and, as it were, sleeping surface. The Ynca, to overcome this difficulty, ordered 4 very large cables to be made of a kind of grass, which covers the lofty heaths and mountains of that country, and by the Indians called Ichu: so that these cables were the foundation of the whole structure. Two of these being laid across the water, fascines of dry juneira, and totora, two species of rushes, were fastened together, and laid across the cables. On this again the two other cables were laid, and covered with similar fascines securely fastened on, but of a smaller size than the first, and arranged so as to form a level surface. And by this means the Ynca procured a safe passage for his army. This bridge of rushes, which is about five yards broad, and one yard and a half above the surface of the water, is carefully repaired, or rebuilt, every six months by the neighbouring provinces, in pursuance of a law made by that Ynca; and since often confirmed by the kings of Spain, on account of its vast use, it being the channel of intercourse between those provinces on each side the Desaguadero.—*ib.*

TITLE for orders, in the church of England, is an assurance of being employed and maintained as an officiating clergyman in some cathedral or parochial church, or other place of Divine worship. And, by the 33*d Canon*, " no one is to be ordained but in order to be a curate or incumbent, or to have some minister's place in some church, or except he be fellow, conduct, or chaplain, in some college in one of the universities, or be master of arts of five years standing, and live there at his own cost." By the same canon, the bishop who ordains a clerk without title, is bound to keep him till he prefer him to some ecclesiastical living.

TIVERTON, a township of Rhode-Island, in Newport county, having the eastern Passage and part of Mount Hope Bay on the W. and N. W. the State of Massachusetts on the N. and E. and Little-Compton township on the south. It contains 2,453 inhabitants, including 25 slaves. It is about 13 miles N. N. E. of Newport.—*Morse.*

TIZON, a river in the N. W. part of S. America, 600 miles from New-Spain. In a journey made thus far, in 1606, the Spaniards found some large edifices, and met with some Indians who spoke the Mexican language, and who told them, that a few days journey from that river, towards the N. was the kingdom of Tollan, and many other inhabited places whence the Mexicans migrated. It is, indeed, confirmed by Mr Stewart, in his late travels, that there are civilized Indians in the interior parts of America. Beyond the Missouri, he met with powerful nations who were courteous and hospitable, and appeared to be a polished and civilized people, having regularly built towns, and enjoying a state of society not far removed from the European; and indeed to be perfectly equal wanted only iron and steel.—*ib.*

TLASCALA, or *Los Angelos*, a province of New-Spain.—*ib.*

TOA, one of the two rivers, Bajamond being the other, which empty into the harbour of Porto Rico, in the island of that name in the West-Indies.—*ib.*

TOAHOUTU, one of the two small islands to the N. eastward of the S. end of Otaha Island, one of the Society Islands, in the South Pacific Ocean.—*ib.*

TOAMENSING, two townships of Pennsylvania; the one in Montgomery county, the other in that of Northampton.—*ib.*

TOBY's *Creek*, an eastern branch of Alleghany river, in Pennsylvania: its southern head water is called Little Toby's Creek. It runs about 55 miles in a W. S. W. and W. course, and enters the Alleghany about 20 miles below Fort Franklin. It is deep enough for batteaux for a considerable way up, thence by a short portage to the W. branch of Susquehannah, by which a good a good communication is formed between Ohio, and the eastern parts of Pennsylvania.—*ib.*

TOCAYMA, a city of Terra Firma, and in New Granada.—*ib.*

TOD OF WOOL, is mentioned in the statute 12 Carol. II. c. 32. as a weight containing 2 stone, or 28 pounds.

TOGOSAHATCHEE *Creek*, a water of Oakmulgee river, in Georgia.—*Morse.*

TOLLAND, a county of Connecticut, bounded N. by the State of Massachusetts, S. by New-London county, E. by Windham, and W. by Hartford county. It is subdivided into 9 townships, and contains 13,106 inhabitants, including 47 slaves. A great proportion of the county is hilly, but the soil is generally strong and good for grazing.—*ib.*

TOLLAND, the chief town of the above county, was incorporated in 1715, and is about 18 miles N. E. of Hartford. It has a Congregational church, courthouse, gaol, and 20 or 30 houses, compactly built, in the centre of the town.—*ib.*

TOLU, a town of Terra Firma, S. America, with a harbour on a bay of the N. Sea. The famous balsam of the same name comes from this place; 114 miles S. W. of Carthagena. N. lat. 9 36, W. long. 75 22. —*ib.*

TOMACO, a large river of Popayan, and Terra Firma, S. America, about 9 miles N. E. of Galla Isle. About a league and a half within the river is an Indian town of the same name, and but small, the inhabitants of which commonly supply small vessels with provisions, when they put in here for refreshment.—*ib.*

TOMAHAWK *Island*, on the east coast of Patagonia, is 24 miles N. E. of Seal's Bay.—*ib.*

TOMBA *River*, on the coast of Peru, is between the port of Hilo and the river of Xuly or Chuly. There is anchorage against this river in 20 fathoms, and clean ground. Lat. 17 50 S.—*ib.*

TOMBIGBEE *River*, is the dividing line between the Creeks and Chactaws. Above the junction of Alabama and Mobile rivers, the latter is called the Tombigbee river, from the fort of Tombigbee, situated on the west side of it, about 96 miles above the town of Mobile. The source of this river is reckoned to be 40 leagues higher up, in the country of the Chickasaws. The fort of Tombigbee was captured by the British, but abandoned by them in 1767. The river is navigable for sloops and schooners about 35 leagues above the town of Mobile: 130 American families are settled on this river, that have been Spanish subjects since 1783.—*ib.*

TOMBUCTOO, a large city in North Africa, and capital of a kingdom of the same name. It has for some years past been the great object of European research, being one of the principal marts for that extensive commerce which the Moors carry on with the Negroes. The hopes of acquiring wealth in this pursuit, and zeal for propagating their religion, have filled this extensive city with Moors and Mahomedan converts; the king himself, and all the chief officers of state are Moors; and they are said to be more severe and intolerant in their principles than any other of the Moorish tribes in this part of Africa. Mr Park was informed, by a venerable old Negro, that when he first visited Tombuctoo, he took up his lodging at a sort of public inn, the landlord of which, when he conducted him into his hut, spread a mat on the floor, and laid a rope upon it; saying, "if you are a Mussulman, you are my friend, sit down; but if you are a Kafir, you are my slave; and with this rope I will lead you to market." The reigning sovereign of Tombuctoo, when Mr Park was in Africa, was named *Abu Abrahima.* He was reported to possess immense riches, and his wives and concubines were said to be clothed in silk, and the chief officers of state live in considerable splendour. The whole expense of his government is defrayed by a tax upon merchandize, which is collected at the gates of the city.

Of that city very little is known with accuracy, as it has never been visited by any European. It is the largest on the Niger, Houssa only excepted; and probably contains from 60,000 to 80,000 inhabitants. In some of the Gazetteers, its houses are said to be built in the form of bells; but they are probably such buildings as those of SEGO, which see in this *Supplement.* Tombuctoo, according to Major Rennel, is in 16° 30′ N. Lat. and 1° 33′ E Long. from Greenwich.

TOMINA, a jurisdiction in the archbishopric of La Plata in Peru. It begins about 18 leagues S. E. from the city of Plata; on its eastern confines dwell a nation of wild Indians, called Chiriguanos. It abounds with wine, sugar and cattle.—*Morse.*

TOMISCANING, a lake of N. America, which sends its waters south eastward through Ottawas river, into Lake St Francis in St Lawrence river. The line which separates Upper from Lower Canada, runs up to this lake by a line drawn due north, until it strikes the boundary line of Hudson's Bay, or New-Britain. —*ib.*

TOMPSONTOWN, a village of Pennsylvania, in Mifflin county, containing about a dozen houses. It is 22 miles from Lewistown.—*ib.*

TOM's *Creek*, in New-Jersey, which separates the towns of Dover and Shrewsbury.—*ib.*

TOMSOOK, in the language of Bengal, a bond.

TONDELO, a river at the bottom of the Gulf of Campeachy, in the S. W. part of the Gulf of Mexico; 15 miles due west of St Annes, and 24 east of Guasickwalp. It is navigable for barges and other vessels of from 50 to 60 tons.—*Morse.*

TONEWANTO, the name of a creek and Indian town, in the north-western part of New-York. The creek runs a westward course and enters Niagara river opposite Grand Island, 8 miles N. of Fort Erie. It runs about 40 miles, and is navigable 28 miles from its mouth. The town stands on its S. side, 18 miles from Niagara river. Also the Indian name of Fishing Bay, on Lake Ontario.—*ib.*

TONGATABOO, one of the Friendly Islands, in the S. Pacific Ocean, about 60 miles in circuit, but rather oblong, and widest at the E. end. It has a rocky coast, except to the N. side, which is full of shoals and islands, and the shore is low and sandy. It furnishes the best harbour or anchorage to be found in these islands. The island is all laid out in plantations, between which are roads and lanes for travelling, drawn in a very judicious manner for opening an easy communication from one part of the island to another. S. lat. 21 9, W. long. 174 46. Variation of the needle, in 1777, was 9 53 E.—*ib.*

TONTI, an island at the mouth of Lake D'Urse, at at the eastern extremity of Lake Ontario, is within the British territories; 11 miles N. E. of Point au Goelans, and 12 W. of Grand Island, having several isles between it and the latter.—*ib.*

TONTI, or *Tonty*, a river which empties through the N. shore of Lake Erie; 22 miles W. by N. of Riviere a la Barbue.—*ib.*

TONTORAL, *Cape*, on the coast of Chili, in S. America, 15 leagues to the N. of Guasca, and in lat. 27 30 S.—*ib.*

TOOBAUAI, one of the Society Islands, in the S. Pacific Ocean, not more than 5 or 6 miles across in any part. S. lat. 23 25, W. long. 149 23.—*ib.*

TOOSCHCONDOLCH, an Indian village on the N. W. coast of N. America, of considerable importance in the fur trade; situated on a point of land between two deep sounds. N. lat. 53 2, W. long. 131 30.—*ib.*

TOOTH-ACHE, a well known excruciating pain (see *Encycl.*), for the alleviation, and even the cure of which, many specifics have been offered to the public. Of one of the most extraordinary of these, there is an account, in a small work published at Florence in 1794, by professor Gerbi, who gives the description of an insect, a kind of *curculio*, which, from its property of allaying the tooth-ache, has received the epithet of *antiodontalgicus*, and which is found on a species of thistle, *carduus spinosissimus*. The flowers of this thistle, when analysed, gave the acid of galls, the muriatic acid, oxalat of lime, extractive matter, and a very little resin. On the bottom of the calyx, which supports the flowers, there are often found excrescences like the gall nut, which are at first spheroidal, afterwards cylindric, and at length assume the figure of two hemispheres: they consist of the like component parts with the flowers, but contain more resin, and far more oxalat of lime; as the gall apple of the oak, according to the experiments of M. Branchi, which are here mentioned, contains more of the acid of galls than the bark and other parts of the oak, in which he could discover no sulphuric acid. The insect, according to the author's observations, eats not only the parenchyma, but also the vessels and fibres of the leaves. The egg, before the worm makes its appearance, is nourished by the sap of the plant, and of the above excrescences, in which it resides, by means of the attractive power that the egg possesses for certain vegetable juices and substances. The excrescences arise by the accumulation of a solid substance, which is precipitated from the nourishing juices of the thistle, diminished by nourishing the egg and the worm. This insect, the eggs of which are deposited in these excrescences, is, together with the *curculio* of the centaury, a new species. It is of a longish figure; covered below with short yellow hair, and above with golden yellow velvety spots. Its corslet is variegated with specks; and the covering of its wings with specks and stripes. It has a short proboscis, and shews some likeness to the *curculio villosus* of Geoffroy. Its larva represents a sort of ichneumon. By chemical analysis it exhibits some traces of common salt; by distillation with a strong dry heat, some volatile lixivious salts; and it contains besides these, some gelatinous, and a little sebaceous and slimy extractive matter. If about a dozen or fifteen of these insects, when in the state of larva, or even when come to perfection, be bruised and rubbed slowly between the fore finger and the thumb, until they have lost their moisture, and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases sometimes instantaneously. This power or property the finger will retain for a year, even though it be often washed and used. A piece of shammoy leather will serve equally well with the finger. Of 629 experiments, 401 were attended with complete success. In two of these cases, the hollow teeth arose from some fault in the juices: in the rest they were merely local. If the gums are inflamed, the remedy is of no avail.

To the truth of this tale the reader will give what credit he pleases; but it is surely very difficult to believe, that a living finger, continually perspiring, can retain for a year the moisture imbibed from this insect. But it seems there are other insects which have the property of curing the tooth-ache; such as the *carabus chrysocephalus* of Rossi; the *carabus ferrugineus* of Fabricius; the *coccinella septem punctata* (the lady bird); the *chrysomela populi*, and the *chrysomela sanguinolenta*. It would appear, therefore, that this property belongs to various kinds of the *coleoptera*.

The idea of these insects being endowed with the property of curing the tooth-ache is not confined to Italy; for Dr Hirsch, dentist to the court of Weimar, asserts (*Verkundiger*, September 24, 1798) that he employed them with the happiest effect, except in some cases where his patients were females. He says, that he took that small insect, found commonly among corn, *coccinella septem punctata*, and bruised it between his fingers. He then rubbed the fingers with which he had bruised it, till they became warm at the points, and touched with them the unsound parts of the gums, as well as the diseased tooth. Dr Hirsch adds, that he made the same experiment a few days after with equal success, though he had not bruised a new insect with his fingers. He seems to think that, to ensure the efficacy of the process, the insect should be alive; because when dead, its internal parts, in which he presumes the virtue chiefly resides, become dried up, leaving only the wings and an empty shell; and therefore proposes to physicians to turn their attention to the finding out of some method for preserving the virtue of the insect so that its efficacy may be in full vigour throughout the year.

Besides these beetles, charcoal has been recommended as an anodyne in the tooth-ache; but whether it operates merely by filling the hollow of the tooth, and thereby preventing the access of atmospheric air to the nerve, or by any of its singular and hitherto unknown qualities, seems not to have been well ascertained.

TOOTOOCH, a small low island in Nootka Sound, on the N. W. coast of North-America, on the eastern side of which is a considerable Indian village; the inhabitants of which wear a garment apparently composed of wool and hair, mostly white, well fabricated, and probably by themselves.—*Morse.*

TOPIA, a mountainous, barren part of New-Biscay province in Mexico, North-America; yet most of the neighbouring parts are pleasant, abounding with all manner of provisions.—*ib.*

TOPSFIELD, a township of Massachusetts, Essex county, containing 780 inhabitants. It is 8 miles westerly of Ipswich, and 39 N. by E. of Boston.—*ib.*

TOPSHAM, a township of Vermont, in Orange county, sham, county, west of Newbury, adjoining. It is watered by some branches of Wait's river, and contains 162 inhabitants.—*ib.*

Topsham, a township of the District of Maine, in Lincoln county, 32 miles in circumference, and more than 25 miles is washed by water. It is bounded on the N. W. by Little river; N. by Bowdoin and Bowdoinham; E. by Cathance and Merry Meeting Bay; S. and S. W. by Amariscoggin river, which separates it from Brunswick in Cumberland county. The inhabitants amount to 826 souls, and they live in such easy circumstances, that none have ever been so poor as to solicit help from the parish. It was incorporated in 1764. A few English attempted to settle here in the end of the last, or beginning of the present century. These were cut off by the natives. Some families ventured to settle in this hazardous situation in 1730; from which period, until the peace of 1763, the inhabitants never felt wholly secure from the natives. It is 37 miles S. by W. of Hallowell, and 156 N. by E. of Boston; and is nearly in lat. 44 N. and long. 70 W. —*ib.*

TOR, a town of Asia, in Arabia Petræa, seated on the Red Sea, with a good harbour, defended by a castle. There is a handsome Greek convent, in whose garden are fountains of bitter water, which they pretend are those rendered sweet by Moses, by throwing a piece of wood into them. Some think that this town is the ancient Elana. E. Long. 31. 25. N. Lat. 28. 0.

TORBAY, a town on the eastern coast of Nova-Scotia; 22 miles S. W. of Roaring Bull Island, and 100 N. E. of Halifax.—*Morse.*

TORBEK, a village on the south side of the south peninsula of the island of St Domingo; 3 leagues N. W. of Avache Island.—*ib.*

Torelli.

TORELLI (Joseph), was born at Verona on the 4th of November 1721. His father Lucas Torelli, who was a merchant, dying while young Torelli was but an infant, he was left entirely to the care of his mother Antonia Albertini, a Venetian lady of an excellent character. After receiving the first rudiments of learning, he was placed under the Ballerini, who, observing the genius of the boy, prevailed upon his mother to send him to complete his education at Patavia. Here he spent four years entirely devoted to study, all his other passions being absorbed by his thirst for knowledge.

The unsullied innocence of his life, and the prudence and gravity of his conduct, soon attracting the attention of his masters, they not only commended him with eagerness, but performed to him the part of parents, conversed with him familiarly about their respective sciences, and read over to him privately the lectures which they had to deliver. This was the case particularly with Hercules Dondinus, under whom Torelli studied jurisprudence. But he by no means confined himself to that science alone. The knowledge which he acquired was so general, that upon whatever subject the conversation happened to turn, he delivered his sentiments upon it in such a manner that one would have thought he had bestowed upon it his whole attention.

After receiving the degree of Doctor, he returned home to the enjoyment of a considerable fortune; which putting it into his power to choose his own mode of living, he determined to devote himself entirely to literary pursuits. He resolved, however, not to cultivate one particular branch to the exclusion of every other, but to make himself master of one thing after another, as his humour inclined him; and he was particularly attentive to lay an accurate and solid foundation. Though he declined practising as a lawyer, he did not on that account, relinquish the study of law. The Hebrew, Greek, Latin, and Italian languages, occupied much of his time. His object was to understand accurately the two first, and to be able to write and speak the two last with propriety and elegance. Besides these languages, he learned French, Spanish, and English. On the last, in particular, he bestowed uncommon pains; for he was peculiarly attached to the British nation, and to British writers, whom he perused with the greatest attention; not merely to acquire the language, but to imbibe also that force and loftiness of sentiment for which they are so remarkable. Nay, he even began an Italian translation of Paradise Lost.

He likewise made himself acquainted with ethics, metaphysics, and polemical divinity; to which last subject he was induced to pay attention by the custom of his country. With ancient history he was very familiarly acquainted, calling in to his assistance, while engaged in that study, the aids of chronology, geography, and criticism. This last art, indeed, by means of which what is counterfeit may be distinguished from what is genuine, what is interpolated from what is uncorrupted, and what is excellent from what is faulty, he carried about with him as his counsellor and his guide upon all occasions.

The theory of *music* he studied with attention, preferring those powerful airs which make their way into the soul, and rouse the passions at the pleasure of the musician. His knowledge of *pictures* was held in high estimation by the artists themselves, who were accustomed to ask his opinion concerning the fidelity of the design, the harmony of colours, the value of the picture, and the name of the painter. He himself had a collection, not remarkably splendid indeed, but exceedingly well chosen. *Architecture* he studied with still greater attention, because he considered it as of more real utility. Nor did he neglect the pursuits of the *antiquarian*, but made himself familiarly acquainted with coins, gems, medals, engravings, antique vessels, and monuments. Indeed scarce any monumental inscriptions were engraved at Verona which he had not either composed or corrected. With the *antiquities* of his own country he was so intimately acquainted, that every person of eminence, who visited Verona, took care to have him in their company when they examined the curiosities of the city.

But these pursuits he considered merely as amusements; mathematics and the belles lettres were his serious studies. These studies are, in general, considered as incompatible; but Torelli was one of the few who could combine the gravity of the mathematician with the amenity of the muses and graces, and who handle the compass and the plectrum with equal skill. Of his progress in mathematics, several of his treatises, and especially his edition of Archimedes, published since his death by the university of Oxford, are sufficient proofs. Nor was his progress in the more pleasing parts of literature less distinguished. In both these studies he was partial to the ancients, and was particularly hostile to the poetry and the literary innovations of the French.

Nothing

Torelli,

Nothing could be purer or more elegant than his Latin style, which he had acquired at the expense of much time and labour. His Latin translation of Archimedes is a sufficient proof of this, and is indeed really wonderful, if we consider that the Romans, being far inferior to the Greeks in mathematical knowledge, their language was of necessity destitute of many necessary words and phrases. He wrote the Italian language with the classic elegance of the 14th and 15th centuries. Witness his different works in that language, both in prose and verse. He translated the whole of Æsop's Fables into Latin, and Theocritus, the *Epithalamium* of Catullus, and the *comedy* of Plautus, called *Pseudolus*, into Italian verse. The two first books of the Æneid were also translated by him with such exactness, and so much in the stile of the original, that they may well pass for the work of Virgil himself.

His life, like his studies, was drawn after the model of the ancient sages. Frugal, temperate, modest, he exhibited a striking contrast to the luxurious manners of his age. In religion he adhered strictly, though not superstitiously, to the opinions of his ancestors. He was firm to his resolutions, but not foolishly obstinate; and so strict an observer of equity, that his probity would have remained inviolate, even though there had been no law to bind him to justice. He never married, that he might have leisure to devote himself, with less interruption, to his favourite studies. Every one readily found admission to him, and no man left him without being both pleased and instructed; such was the sweetness of his temper, and the readiness with which he communicated information. He adhered with great constancy to his friendships. This was particularly exemplified in the case of Clemens Sibiliatus, who has favoured the world with the life of Torelli. With him he kept up the closest connection from a school boy till the day of his death. He was peculiarly attached likewise to many men of distinction, both in Italy and Britain. He died in August 1781, in the 70th year of his age.

The following is a complete list of his works, his edition of Archimedes excepted, which was not published till after his death:

1. "Lucubratio Academica, sivi Somnium Jacobi Pindemontii, &c." Patavii, 1743.—2. "Animadversiones in Hebraicum Exodi Librum et in Græcum lxx Interpretationem;" Veronæ, 1744.—3. "De principe Gulæ incommodo, ejusque remedio, Libri duo;" Coloniæ Agrippinæ, 1744.—4 "De Probabili Vitæ Morumque Regula;" Colon æ, 1747.—5. "Li due primi Canti dell' Iliade (di Scipione Maffei) e lie due primi dell' Eneide di Giuseppe Torelli tradotti in versi Italiani;" Verona, 1749.—6. "Gli stessi due canti dell' Eneide ristampati soli lo stesso anno per lo stesso Ramanzini."—7. "Scala de Meriti a capo d'anno Trattato Geometrico;" Verona, 1751.—8. "De Nihilo Geometrico, lib. 2.;" Veronæ, 1758.—9. "Lettera intorno a due passi del Purgatorio di Dante Alighiero;" *ib.* 1760.—10. "Della Denominazione del corrente anno vulgarmente detto 1760 in Bologna per Lelio della Volpe."—11. "Il pseudolo. Comedia, &c. e si aggiunge la traduzione d'alcuni Idilli di Teocritoe di Mosco;" Firenze, 1765.—12. "Inno a Maria Virgine nella Festivita della sua Concezione;" Verona, 1766.—13. "Lettera a Miladi Vaing-Reit premessa al libro che ha per titalo xii. lettere Inglesi, con altra lettera all'autore della suddetta;" Verona, 1767.—14. "Elegia di Tommaso Gray, Poeta Inglese, in un Cimetero Campestre in versi Italiani rimati;" Verona, 1767.—15. "Geometrica;" Veronæ, 1769.—16. "Demonstratio antiqui Theorematis de motuum commixtione;" Veronæ, 1774.—17. "Lettera supra Dante contro il Signor di Voltaire;" Verona, 1781.—18. "Poemetto di Catullo su le Nozze di Peleo e Tetite, ed un Epitalamio dello stesso;" 1781.—19. "Œsopi Fabulæ."—20. "Teocrito tradotto, in versi Toscani."—21. "Elementi d'Euclide tradotti nell idioma Italiano."—22. "Elementorum Prospectivæ, libri duo."

TORMENTIN *Cape*, on the W. side of the Straits of Northumberland, or Sound, between the island of St John's and the E. coast of Nova-Scotia, is the N. point of the entrance to Bay Vert. It is due west from Governor's Island, on the S. E. coast of the island of St John's. In some maps this point is called *Cape Sturm.*—*Morse.*

TORONTO, a British settlement on the north-western bank of Lake Ontario, 53 miles N. by W. of Fort Niagara. N. lat. 44 1, W. long. 79 10 —*ib.*

TORPEDO, or CRAMP FISH, has been described under the generic title RAJA; and an attempt made to explain its electrical phenomena in the article ELECTRICITY, n° 258, &c. (Both these articles are in the *Encyclopædia*). From some late discoveries, however, of Volta and others, the shock given by the torpedo appears much more analagous to the shock of GALVANISM than to that of common electricity; and even the electrical organs of the fish seem to resemble the apparatus with which those discoveries in galvanism were made.

In the 63d volume of the Philosophical Transactions, Mr Hunter describes the electric organ of the torpedo as consisting of a number of columns varying in their length from an inch and a half to a quarter of an inch, with diameters about two-tenths of an inch. The number of columns in each organ of the torpedo which he presented to the Royal Society was about 470; but in a very large torpedo which he dissected, the number of columns in one organ was 1182. These columns were composed of films parallel to the base of each; and the distance between each partition of the columns was $\frac{1}{150}$th of an inch. From these facts, the reader will find the anomalies of torpedinal electricity (supposing it the same with common electricity) accounted for in a very ingenious and philosophical manner by Mr Nicholson, at p. 358 of the first volume of his valuable journal. We pass on, however, to point out the resemblance between it and the lately discovered phenomena in galvanism.

Take any number of plates of copper, or which is better, of silver, and an equal number of tin, or, which is much better, of zinc, and a like number of discs, or pieces of card, or leather, or cloth (A), or any porous substance

(A) Woollen or linen cloth appear to be more durable, and more speedily soaked, than card.

ſubſtance capable of retaining moiſture. Let theſe laſt be ſoaked in pure water, or, which is better, ſalt and water or alkaline leys. The ſilver or copper may be pieces of money. Build up a pile of theſe pieces; namely, a piece of ſilver, a piece of zinc, and a piece of wet card: then another piece of ſilver, a piece of zinc, and a piece of wet card; and ſo forth, in the ſame order (or any other order, provided the pieces ſucceed each other in their turn), till the whole number intended to be made uſe of is builded up. The inſtrument is then completed.

In this ſtate it will afford a perpetual current of the galvanic influence through any conductor communicating between its upper and lower plates; and if this conductor be an animal, it will receive an electrical ſhock as often as the touch is made, by which the circuit is completed. Thus if one hand be applied to the lower plate, and the other to the upper, the operator will receive a ſhock, and that as often as he pleaſes to lift his finger and put it down again.

This ſhock reſembles the weak charge of a battery of immenſe ſurface; and its intenſity is ſo low that it cannot make its way through the dry ſkin. It is therefore neceſſary that a large ſurface of each hand ſhould be well wetted, and a piece of metal be graſped in each, in order to make the touch; or elſe that the two extremities of the pile ſhould communicate with ſeparate veſſels of water, in which the hands may be plunged.

The commotion is ſtronger the more numerous the pieces. Twenty pieces will give a ſhock in the arms, if the above precautions be attended to. One hundred pieces may be felt to the ſhoulders. The current acts on the animal ſyſtem while the circuit is complete, as well as during the inſtant of commotion, and the action is abominably painful at any place where the ſkin is broken.

That this influence, whatever it may be, has a ſtriking reſemblance to the repeated ſhocks given by the torpedo, is obvious; but what it really is in itſelf muſt be aſcertained, if it can be aſcertained at all, by future experiments. Mr Nicholſon indeed, from whoſe Journal we have taken this account of Volta's apparatus and its effects, ſeems confident that theſe effects proceed from an electrical ſtream or current; but this mode of operation is quite foreign from all the laws of electricity known to us. The galvanic influence in this apparatus appears to move perpetually in a circle; to which we are acquainted with no fact in electricity that is at all ſimilar. Galvaniſm, too, ſeems capable of accumulation, even while ſurrounded by conducting ſubſtances, which is quite inconſiſtent with all that we *diſtinctly* know of electricity and its laws.

That the energy of the apparatus, however, is the effect of an electric ſtream or current, our ingenious author thinks proved by the condenſer with which Sig. Volta aſcertained the kind of the electricity, and obtained its ſpark. He finds the action ſtrongeſt, or moſt pungent, on wounds on the minus ſide of the apparatus, or where the wounds give out electricity; a fact alſo obſervable in the common electric ſpark.

The theory of the learned inventor ſeems to be, that it is a property of ſuch bodies as differ in their power of conducting electricity, that when they are brought into contact they will occaſion a ſtream of the electric matter. So that if zinc and ſilver be made to communicate immediately by contact, there will be a place of good conducting energy; and if they be made to communicate mediately by means of water, there will be a place of inferior conducting energy: and wherever this happens, there will be a ſtream or current produced in the general ſtock of electricity. This is not deduced as the conſequence of other more ſimple facts; but is laid down as a general or ſimple principle grounded on the phenomena. If ſo, is it not a *petitio principii?* That ſuch bodies as zinc and ſilver, when properly diſpoſed, pruduce a ſtream or current, or ſomething analogous to a ſtream or current, in the galvanic fluid, follows indeed indiſputably from the phenomena; but it by no means follows from the ſame phenomena that galvaniſm is electricity; for electricity ſeems ſubject to different laws. See Electricity and Thunder, both in this *Supplement*.

It muſt be acknowledged that the diſcovery of the galvanic ſhock and ſpark, and of the apparent exiſtence of two oppoſite ſtates of galvaniſm correſponding to poſitive and negative electricity, conſiderably increaſe the analogy; which in the article Galvanism, *Suppl.* we have admitted to be very ſtriking: but ſuppoſing no fallacy in any of Volta's experiments, we do not think that theſe diſcoveries amount to any thing like a demonſtration of the concluſions which have been drawn from them. It is by no means certain that light is eſſentially connected with the electric fluid; for we know that it is not eſſentially connected with heat; (See *Thermometrical Spectrum*, in this *Suppl.*) The flaſh, for example, of lightning may be merely an extrication of light, in conſequence of the action of electricity upon the atmoſphere in its paſſage, or on the bodies upon which it impinges; and there are many inſtances of a ſimilar extrication, as in the colliſion of two pieces of flint, where neither electricity nor galvaniſm were ever ſuſpected to have any ſhare in producing the phenomenon. Why may not the progreſs of the galvanic fluid have a ſimilar effect in this inſtance with that of electricity, though the two fluids be eſſentially different between themſelves? But we have more to ſay on this ſubject.

Meſſrs Nicholſon and Carliſle conſtructed an apparatus ſimilar to that of Volta, which gave them a ſhock as before deſcribed, and a very acute ſenſation wherever the ſkin was broken. Their firſt reſearch was directed to aſcertain that the ſhock they felt was really an electrical phenomenon. For this purpoſe the pile was placed upon Bennett's gold leaf electrometer, and a wire was then made to communicate from the top of the pile to the metallic ſtand or foot of the inſtrument; ſo that the circuit of the ſhock would have been through the leaves, if they had diverged; but no ſigns of electricity appeared. Recourſe was then had to the revolving doubler; of which the reader will find an account in our Supplementary article Electricity, nº 203. The doubler had been previouſly cleared of electricity by twenty turns in connection with the earth. The negative divergence was produced in the electrometer. Repeated experiments of this kind ſhewed that the ſilver end was in the minus, and the zinc end in the plus ſtate.

Here a pile of 17 half crowns, with a like number of pieces of zinc, and of paſteboard ſoaked in ſalt water, though it gave a ſevere ſhock, exhibited no ſymptoms of of electricity till affifted by the doubler. Will it be faid that this arofe from want of intenfity in the galvanic fhock? We can only reply, that a much lefs intenfe fhock of electricity would have produced a fenfible divergence in the inftrument without the doubler. What was the caufe of this difference? We have, however, no doubt but that electricity was concerned in this phenomenon; for we have fhewn elfewhere (fee THUNDER, *Suppl.*), that either *electricity* is produced, or the equilibrium of the electrical fluid difturbed, by every chemical folution; and we fhall fee immediately that chemical folutions are perpetually going on in Volta's apparatus.

Very early in the courfe of this experiment, the contacts being made fure by placing a drop of water upon the upper plate, Mr Carlifle obferved a difengagement of gas round the touching wire. This gas, though very minute in quantity, evidently feemed to have the fmell afforded by hydrogen when the wire of communication was fteel. This, with fome other facts, led Mr Nicholfon to propofe to break the circuit by the fubftitution of a tube of water between two wires. They therefore inferted a brafs wire through each of two corks inferted in a glafs tube of half an inch internal diameter. The tube was filled with New River water, and the diftance between the points of the wires in the water was one inch and three quarters. This compound difcharger was applied fo that the external ends of its wire were in contact with the two extreme plates of a pile of 36 half crowns, with the correfponding pieces of zinc and pafteboard. A fine ftream of minute bubbles immediately began to flow from the point of the lower wire in the tube which communicated with the filver, and the oppofite point of the upper wire became tarnifhed, firft deep orange, and then black. On reverfing the tube, the gas came from the other point, which was now loweft; while the upper, in its turn, became tarnifhed and black. Reverfing the tube again, the phenomena again changed their order. In this ftate the whole was left for two hours and a half. The upper wire gradually emitted whitifh filmy clouds, which, towards the end of the procefs, became of a pea-green colour, and hung in perpendicular threads from the extreme half inch of the wire, the water being rendered femiopaque by what fell off, and in a great part lay, of a pale green, on the lower furface of the tube, which, in this difpofition of the apparatus, was inclined about forty degrees to the horizon. The lower wire of three quarters of an inch long, conftantly emitted gas, except when another circuit, or complete wire, was applied to the apparatus; during which time the emiffion of gas was fufpended. When this laft mentioned wire was removed, the gas re-appeared as before, not inftantly, but after the lapfe of four beats of a half fecond clock ftanding in the room. The product of gas, during the whole two hours and a half, was two-thirtieths of a cubic inch. It was then mixed with an equal quantity of common air, and exploded by the application of a lighted waxed thread.

Meffrs Nicholfon and Carlifle had been led, by their reafoning on the firft appearance of hydrogen, to expect a decompofition of the water; but it was with no little furprize that they found the hydrogen extricated at the contact with one wire, while the oxygen fixed itfelf, in combination with the other wire, at the diftance of almoft two inches. This new fact ftill remains to be explained, and feems, fays Mr Nicholfon, to point at fome general law of the agency of electricity in chemical operations. Does it not as naturally fuggeft a fufpicion that galvanifm is not electricity; efpecially as we are informed, by Mr Cruickfhank of Woolwich, that Meffrs Nicholfon and Carlifle difcovered, that "galvanifm decompofes water with much greater facility than electricity, and with phenomena fomewhat different?" What the particular differences are, he does not fay; but we learn from Mr Nicholfon himfelf, that from the general tenor of his experiments, it appears to be eftablifhed, that the decompofition of water by galvanifm is more effectual the lefs the diftance is between the wires, but that it ceafes altogether when the wires are in contact.

Mr Nicholfon concludes his memoir with mentioning concifely the effects of a pile of 100 half crowns, and a chemical incident, which appears to be the moft remarkable of thofe which he has yet obferved.

The pile was fet up with pieces of green woollen cloth foaked in falt water. It gave fevere fhocks, which were felt as high as the fhoulders. The tranfition was much lefs forcible through a number of perfons, but it was very perceptible through nine. The fpark was frequently vifible when the difcharge was made in the dark, and a gleam of light was alfo, in fome inftances, feen about the middle of the column at the inftant of the explofion. The affiftants were of opinion that they heard the fnap.

The extrication of the gafes was rapid and plentiful by means of this apparatus. When copper wires were ufed for the broken circuit, with muriatic acid diluted with 100 parts of water in the tube, no gas, nor the leaft circulation of the fluid was perceived, when the diftance of the wires was two inches. A fhort tube, with two copper wires very near each other in common water, was made part of the circuit, and fhewed by the ufual phenomena, that the ftream of electricity was rapidly paffing. The wires in the muriatic acid were then flided within the third of an inch of each other. For the fake of brevity he avoids enumerating the effects which took place during feveral hours, and fimply ftates, that the minus wire gave out fome hydrogen during an hour; while the plus wire was corroded, and exhibited no oxyd; but a depofition of copper was formed round the minus, or lower wire, which began at its lower end: that no gas whatever appeared in this tube during two hours, though the depofition was going on, and the fmall tube fhewed the continuance of the electric ftream; and that the depofition, at the end of four hours, formed a ramified metallic vegetation, nine or ten times the bulk of the wire it furrounded.

In this experiment, it appeared that the influence of electricity increafing the oxydability of the upper wire, and affording nafcent hydrogen from the lower, caufed the latter to act as the precipitant of a folution of one and the fame metal.

Mr Nicholfon, we fee, continues to call it electricity with the utmoft confidence, as if it could not poffibly be any thing elfe; and yet he fays that the galvanic fhock is much lefs forcible when paffed through a number of perfons than when paffed only through one. This, we believe, does not hold in the fhocks of common electricity; and the difference probably arifes from the cuticle

ticle obftructing the paffage of the one and not of the other. Volta himfelf fays, that *this* electricity, for he too is defirous to prove it electricity, does not diffufe itfelf through the air. It is fo univerfally known that very dry air is no conductor of electricity, that he muft mean, on this occafion, air not uncommonly dry; otherwife the non-diffufion of *this* electricity through air would not diftinguifh it, as he feems to admit it does, from common electricity. But what occafions this diftinction, if the two electricities be the fame?

Lieutenant-colonel Haldane, well known in the fcientific world, made experiments with Volta's pillar, both in a horizontal and in a vertical pofition. With a large pillar, placed vertically, he obtained very weak figns of electricity. He connected the apparatus with the conductor of an electrical machine, and found the effect rather impeded than affifted by the common electric ftream. He placed the plate of Bennet's electrometer in the circuit, without producing electric figns. He found that the galvanic apparatus, placed between the outfide and infide of a jar, prevented its charging, and that it is alfo capable of conducting the charge, though not rapidly: and, on the whole, from the very minute exhibition of the attractive and repellent powers, while the caufticity, the fhock, and the oxydation, are fo very powerful, he cannot be perfuaded that electricity is the principal agent, though fome might be generated, or difengaged, during the operation of the apparatus.

This is exactly our own opinion, which is ftrongly corroborated by the refults of fome very curious experiments made by Mr Cruickfhank of Woolwich. Thefe experiments our limits permit us not to detail. They were made with a view to afcertain the nature and relative proportions of the gafes obtained from water and other fluids by this influence; and the author thinks himfelf authorifed to conclude from them:

1. That hydrogen gas, mixed with a very fmall proportion of oxygen and ammonia, is fomehow difengaged at the wire connected with the filver extremity of the machine; and that this effect is equally produced, whatever the nature of the metallic wire may be, provided the fluid operated upon be pure water.

2. That where metallic folutions are employed inftead of water, the fame wire which feparates the hydrogen revives the metallic calx, and depofits it at the extremity of the wire in its pure metallic ftate; in this cafe no hydrogen gas is difengaged. The wire employed for this purpofe may be of any metal.

3. That of the earthy folutions, thofe of magnefia and argil only are decompofed by the filver wire; a circumftance which ftrongly favours the production of ammonia.

4. That when the wire connected with the zinc extremity of the pile confifts either of gold or platinum, a quantity of oxygen gas, mixed with a little azote and nitrous acid, is difengaged; and the quantity of gas thus obtained is a little better than ⅓d of the hydrogen gas feparated by the filver wire at the fame time.

5. That when the wire connected with the zinc is filver, or any of the imperfect metals, a fmall portion of oxygenous gas is likewife given out; but the wire itfelf is either oxydated or diffolved, or partly oxydated and partly diffolved: indeed, the effect in this cafe produced upon the metal is very fimilar to that of the concentrated nitrous acid, where a great deal of the metal is oxydated, and but a fmall quantity held in folution.

6. That when the gafes obtained by gold or platinum wires are collected together and exploded over mercury, the whole nearly difappears and forms water, with probably a little nitrous acid; for there was always a thick white vapour perceived for fome time after the explofion. The refiduary gas, in this cafe, appeared to be azote.

In reflecting on thefe experiments, it would appear that in fome of them the water muft be decompofed: but how this can be effected is by no means fo eafily explained. For example, it feems extremely myfterious how the oxygen fhould pafs filently from the extremity of the filver wire to that of the zinc wire, and there make its appearance in the form of gas. It is to be obferved, likewife, that this effect takes place which ever way the wires are placed, and whatever bends may be interpofed between their extremities, provided the diftance be not too great. On confidering thefe facts more minutely, it appeared to Mr Cruickfhank that the eafieft and fimpleft mode of explanation would be, to fuppofe that the galvanic influence (whatever it may be) is capable of exifting in two ftates, that is, in an oxygenated and deoxygenated ftate; that when it paffes from metals to fluids containing oxygen, it feizes their oxygen, and becomes oxygenated; but when it paffes from the fluid to the metal again, it affumes its former ftate, and becomes deoxygenated. Now when water is the fluid interpofed, and the influence enters it from the filver fide deoxygenated (and we fuppofe that it always paffes from the deoxygenated to the oxygenated fide), it feizes the oxygen of the water, and difengages the hydrogen, which accordingly appears in the form of gas; but when the influence enters the zinc wire, it parts with the oxygen, with which it had formerly united; and this either efcapes in the form of gas, unites with the metal to form an oxyd, or, combined with a certain portion of water, &c. may, according to the German chemifts, form nitrous acid. When a metallic folution is the interpofed fluid, the effect produced may be explained in two ways; but the fimpleft is to fuppofe that the influence, in paffing from the filver wire, feizes the oxygen of the metallic calx, and afterwards depofits it on entering the zinc one. In this cafe no gas fhould appear at the filver wire; but when a perfect metal is employed, oxygen fhould be difengaged from the zinc wire: and this, as has been already mentioned, is exactly what takes place.

What our author confiders as the ftrongeft argument in favour of this hypothefis, and what we confider as an argument equally ftrong to prove that galvanifm differs effentially from electricity, is, that all fluids which do not contain oxygen, are incapable of tranfmitting the galvanic fluid, fuch as alcohol, æther, the fat, and effential oils, as he has proved by direct experiment; but on the contrary, that all thofe which do contain oxygen conduct it more or lefs readily, as all aqueous fluids, metallic folutions, and acids, more efpecially the concentrated fulphuric acid; which it decompofes. In this laft inftance, the oxygen produced can hardly be afcribed to the decompofition of water; for this acid, when properly concentrated, does not contain any fenfible quantity. By this theory alfo we can readily explain the oxydation of the zinc plates in the machine; where the fluid in paffing from the different pairs of plates appears to be alternately oxygenated and deoxygenated. Although I am not (fays Mr Cruickfhank) by any means entirely fatisfied with this hypothefis, yet as it is the only one by which I can explain the different phenomena, it was thought advifable to throw it out, merely with a view to induce others to reafon upon the fubject, and to incite them to make experiments, by which alone truth can be afcertained.

We approve heartily of his conduct. It is for the fame reafon, and not to maintain at all hazards any preconceived opinion of our own, that we have urged every objection that occurs to us againft the hypothefis of the identity of galvanifm and electricity. Thefe fluids or influences appear to us to differ effentially; but ftill we admit that future experiments and future reafonings *may remove* our objections, which, however, ought never to be loft fight of *till* they be removed. If ingenious men, adopting implicitly the hypothefis of Volta and Mr Nicholfon, fhall inftitute a fet of experiments to afcertain the laws of the galvanic influence, they will be very apt to make their experiments fupport their hypothefis, inftead of employing them as guides to the temple of truth. Mr Nicholfon fays, that in all the experiments made by him and Mr Carlifle, the action of the inftrument was freely tranfmitted through the ufual conductors of electricity (meaning, we fuppofe, metals and watery fluids), but that it was ftopped by glafs and other non-conductors. We have experienced the fame thing, and fo far we acknowledge a ftriking refemblance between galvanifm and electricity; but, on the other hand, we have never been able to make any accumulation of galvanifm by means of coated electrics, whilft Mr Cruickfhank found that the galvanic influence cannot be tranfmitted through alcohol, ether, or effential oils. In thefe inftances, the difference between galvanifm and electricity feems to be as ftriking as the refemblance is in the others. Indeed thefe differences between the one and the other are fo many and fo great, that M. Fabbroni attributes the phenomena of galvanifm not to electricity, but to a chemical operation; to the tranfition of oxygen into a combination, and to the formation of a new compound. He had obferved, in repeating the common experiment, that if he wiped his tongue as accurately as poffible, the fenfation of tafte excited by the two metals was fo diminifhed as to be hardly diftinguifhed. The faliva, or fome other moifture, muft therefore be of fome importance in this phenomenon. He afterwards inftituted a fet of very proper experiments; from which it appeared to him that an evident chemical action takes place in the operations of galvanifm, and that it is unneceffary to feek farther for the nature of the new ftimulus. Galvanifm (he fays) is manifeftly a combuftion or oxydation of the metals; and the ftimulating principle may be either the caloric which is difengaged, or the oxygen which paffes into new combinations; or the new metallic falt; but which of thefe he has not afcertained.

Without adopting or rejecting thefe conclufions, we recommend them to the attention of our chemical readers; for it is only by expert and fcientific chemifts that we expect the nature and properties of galvanifm to be afcertained. In the mean time it is proper to obferve, that the pile of Volta continues in order for about three days, and fcarcely three; and that on account of the corrofion of the fæces of the zinc, it is neceffary to renew them previous to each conftruction of the pile. This may be done by fcraping or grinding, or by cleaning them with diluted muriatic acid.

To avoid the trouble of conftantly repiling the pieces of filver and zinc, Mr Cruickfhank conftructed a kind of trough of baked wood, 26 inches in length, 1.7 inches deep, and 1.5 inches wide; in the fides of this trough grooves were made oppofite to each other about the tenth of an inch in depth, and fufficiently wide to admit one of the plates of zinc and filver when foldered together; three of thefe grooves were made in the fpace of one inch and three tenths, fo that the whole machine contained 60 pair of plates. A plate of zinc and filver, each 1 6 inches fquare, well cemented together, were introduced into each of thefe grooves or notches, and afterwards cemented into the trough by a compofition of rofin and wax, fo perfectly that no water could pafs from one cell to the other, nor between the plates of zinc and filver. This circumftance muft be ftrictly attended to, elfe the machine will be extremely imperfect. When all the plates were thus fecured in the trough, the interftices or cells formed by the different pairs of plates were filled with a folution of the muriat of ammonia, which here fupplied the place of the moiftened papers in the pile, but anfwered the purpofe much better. It is hardly neceffary to obferve, that in fixing the zinc and filver plates, they muft be placed regularly, as in the pile, *viz.* alternately zinc and filver, the filver plate being always on the fame fide. When a communication was made between the firft and laft cell, a ftrong fhock was felt in the arms, but fomewhat different from that given by the pile, being quicker, lefs tremulous, and bearing a greater refemblance to the common electrical fhock. He conftructed two of thefe machines, which contained in all 100 pair of plates; thefe when joined together gave a very ftrong fhock, and the fpark could be taken in the day time at pleafure; but what furprifed him not a little, was the very flender power which they poffeffed in decompofing water: in this refpect they were certainly inferior to a pile of 30 pair, although fuch a pile would not give a fhock of one third the ftrength.

This apparatus retained its power for many days, and would in all probability have retained it much longer, had not the fluid got between the dry furfaces of the metals. To remedy this defect, he foldered the zinc and filver plates together, and found that this method anfwers very well. The zinc plates may be cleaned at any time, by filling the different cells for a few minutes with the dilute muriatic acid. Although this apparatus may not entirely fuperfede the pile, efpecially if it fhould be found to decompofe water, &c. but flowly, yet in other refpects it will no doubt be found very convenient and portable.

If this article be thought long, and if we appear to have loft fight of our original fubject, the *Torpedo*, we have only to plead in excufe for our conduct, that whilft we could not avoid pointing out the refemblance between the fhock given by the torpedo and that by Volta's apparatus, we felt it a kind of duty to embrace the only opportunity that we fhall have of laying before our readers the additional information refpecting the phenomena of Galvanism which we have received ed fince the publication of that article. Thefe phenomena are yet new, and they are unqueftionably important; indeed fo very important, that to us it appears neither impoffible, nor even improbable, that to the galvanic agency of metals and minerals may be attributed volcanoes and earthquakes.

TORRINGTON, or *Bedford's Bay*, on the fouthern coaft of Nova-Scotia, and its entrance is at America Point, about 3 miles N. of the town of Halifax. It has from 10 to 13 fathoms at its mouth, but the bay is almoft circular, and has from 14 to 50 fathoms water in it. A prodigious fea fets into it in winter.—*Morse.*

TORRINGTON, a townfhip of Connecticut, in Litchfield county, 8 miles N. of Litchfield.—*ib.*

TORTOISES, *the River of*, lies 10 miles above a lake 20 miles long, and 8 or 10 broad, which is formed by the Miffiffippi in Louifiana and Florida. It is a large fine river, which runs into the country a good way to the N. E. and is navigable 40 miles by the largeft boats.—*ib.*

TORTUE, an ifland on the N. fide of the ifland of St Domingo, towards the N. W. part, about 9 leagues long from E. to W. and 2 broad. The W. end is nearly 6 leagues from the head of the bay of Moustique. The freebooters and buccaniers drove the Spaniards from this ifland in 1632; in 1638, the Spaniards maffacred all the French colony; and in 1639, the buccaniers retook Tortue. In 1676, the French took poffeffion of it again.—*ib.*

TORTUGAS, *Dry*, fhoals to the weftward, a little foutherly from Cape Florida, or the S. Point of Florida, in North-America. They are 134 leagues from the bar of Penfacola, and in lat. 24 32 N. and long. 83 40 W. They confift of 10 fmall iflands or keys, and extend E. N. E. and W. S. W. 10 or 11 miles; moft of them are covered with bufhes, and may be feen at the diftance of four leagues. The fouth-weft key, one of the fmalleft, but the moft material to be known, is in lat. 24 32 N. and long. 83 40 W. From the S. W. part of this key, a reef of coral rocks extends about a quarter of a mile; the water upon it is vifibly difcoloured.—*ib.*

TORTUGAS HARBOUR, *Turtle's Harbour*, or *Barracco de Tortugas*, on the coaft of Brazil, in S. America, is 60 leagues at E. S. E. from the point or cape of Arbrafec, or Des Arbres Sec, and the fhore is flat all the way from the gulf of Maranhao.—*ib.*

TORTUGAS, an ifland fo named from the great number of turtle found near it, is near the N. W. part of the ifland of St Domingo.—*ib.*

TORTUGAS, or *Sal Tortuga*, is near the W. end of New-Andalufia and Terra Firma. It is uninhabited, although about 30 miles in circumference, and abounding with falt. N. lat. 11 36, W. long. 65. It is 14 leagues to the weft of Margaritta Ifland, and 17 or 18 from Cape Blanco on the main. There are many iflands of this name on the north coaft of South-America.—*ib.*

TORTUGAS *Point*, on the coaft of Chili, and in the South Pacific Ocean, is the fouth point of the port of Coquimbo, and 7 or 8 leagues from the Pajaros Iflands. Tortugas road is round the point of the fame name, where fhips may ride in from 6 to 10 fathoms, over a bottom of black fand, near a rock called the Tortugas. The road is well fheltered, but will not contain above 20 or 30 fhips fafely. Ships not more than 200 tons burden may careen on the Tortugas rock.—*ib.*

TOSQUIATOSSY *Creek*, a north head water of Alleghany river, whofe mouth is eaft of Squeaughta Creek, and 17 miles north-wefterly of the *Ichua Town.*—*ib.*

TOTOWA, a place or village at the Great Falls in Paffaik river, New-Jerfey.—*ib.*

TOTTERY, a river which empties through the fouth-eaftern bank of the Ohio, and is navigable with batteaux to the Occafioto Mountains. It is a long river, and has few branches, and interlocks with Red Creek, or Clinche's river, a branch of the Tenneffee. It has below the mountains, efpecially for 15 miles from its mouth, very good land.—*ib.*

TOUCAN, or AMERICAN GOOSE, is one of the modern conftellations of the fouthern hemifphere, confifting of nine fmall ftars.

TOULON, a townfhip of New-York, in Ontario county. In 1796, 93 of the inhabitants were electors.—*Morse.*

TOWERHILL, a village in the townfhip of South-Kingftown, Rhode-Ifland, where a poft-office is kept. It is 10 miles weft of Newport, and 282 from Philadelphia.—*ib.*

TOWNSHEND, a townfhip of Windham county, Vermont, weft of Weftminfter and Putney, containing 676 inhabitants.—*ib.*

TOWNSHEND, a townfhip of Middlefex county, Maffachufetts, containing 993 inhabitants. It was incorporated in 1732, and lies 45 miles northward of Bofton.—*ib.*

TOWNSHEND, a harbour on the coaft of the Diftrict of Maine, where is a bold harbour, having 9 fathoms water, fheltered from all winds. High water, at full and change, 45 minutes after 10 o'clock.—*ib.*

TRACADUCHE, now *Carleton*, a fettlement on the northern fide of Chaleur Bay, about 5 leagues from the great river Cafquipibiac, in a fouth-weft direction. It is a place of confiderable trade in cod-fifh, &c.—*ib.*

TRACTORS, METALLIC. See PERKINISM in this *Suppl.*

TRACTRIX, in geometry, a curve line, called alfo CATENARIA; which fee, *Encycl.* and ARCH, *Suppl.*

TRADESCANT (John), an ingenious naturalift and antiquary, was, according to Anthony Wood, a Fleming or a Dutchman. We are informed by Parkinfon, that he had travelled into moft parts of Europe, and into Barbary; and from fome emblems remaining upon his monument in Lambeth church-yard, it plainly appears that he had vifited Greece, Egypt, and other eaftern countries. In his travels, he is fuppofed to have collected, not only plants and feeds, but moft of thofe curiofities of every fort which, after his death, were fold by his fon to the famous Elias Afhmole, and depofited in his mufeum at Oxford. When he firft fettled in England cannot, at this diftance of time, be afcertained. Perhaps it was at the latter end of the reign of Queen Elizabeth, or the beginning of that of King James I. His print, engraven by Hollar before the year 1656, which reprefents him as a perfon very far advanced in years, feems to countenance this opinion. He lived in a great a great house at South Lambeth, where his museum was frequently visited by persons of rank, who became benefactors thereto: among these were King Charles I. (to whom he was gardener), Henrietta Maria his Queen, Archbishop Laud, George Duke of Buckingham, Robert and William Cecil, Earls of Salisbury, and many other persons of distinction. John Tradescant may therefore be justly considered as the earliest collector (in England) of every thing that was curious in natural history, viz. minerals, birds, fishes, insects, &c. He had also a good collection of coins and medals of all sorts, besides a great variety of uncommon rarities. A catalogue of these, published by his son, contains an enumeration of the many plants, shrubs, trees, &c. growing in his garden, which was pretty extensive. Some of these plants are, if not totally extinct, at least become very uncommon, even at this time: though this able man, by his great industry, made it manifest, in the very infancy of botany, that there is scarce any plant extant in the known world that will not, with proper care, thrive in England.

When his house at South Lambeth, then called *Tradescant's Ark*, came into Ashmole's possession, he added a noble room to it, and adorned the chimney with his arms, impaling those of Sir William Dugdale, whose daughter was his third wife; where they remain to this day.

It were much to be wished, that the lovers of botany had visited this once famous garden before, or at least in the beginning of the present century. But this seems to have been totally neglected till the year 1749, when Dr Watson and the late Dr Mitchell favoured the Royal Society with the only account now extant of the remains of Tradescant's garden.

When the death of John Tradescant happened is not known; no mention being made thereof in the register-book of Lambeth church.

TRAJECTORY, a term often used, generally for the path of any body, moving either in a void, or in a medium that resists its motion; or even for any curve passing through a given number of points. Thus Newton, Princip. lib. 1. prop. 22. proposes to describe a trajectory that shall pass through five given points.

TRAITOR's Island, one of the Archipelago called Navigator's *Islands*, in the South Sea (See that article, *Suppl.*). It is low and flat, with only a hill of some height in the middle; and is divided into two parts by a channel, of which the mouth is about 150 toises wide. It abounds with bannanas, yams, and the finest cocoa-nuts, which Perouse says he ever saw. About twenty canoes approached the French ships without dread, traded with a good deal of honesty, and never refused, like the natives of the archipelago of Navigators, to give their fruit before they were paid for it; nor, like them, did they give a preference to beads over nails and pieces of iron. They spoke, however, the same language, and had the same ferocious look; their dress, their manner of tatowing, and the form of their canoes, were the same; nor could we (says the author) doubt that they were one and the same people: they differed, indeed, in having universally two joints cut off from the little finger of the left hand; whereas, in the islands of Navigators, I only perceived two individuals who had suffered that operation. They were also of much lower stature, and far less gigantic make; a difference proceeding, no doubt, from the soil of these islands, which being less fertile, is consequently less favourable to the expansion of the human frame.

TRAMMELS, in mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins, which slide in those grooves, and also the describing pencil. All the engines for turning ovals are constructed on the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it; in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a demonstration of the chief properties of these instruments by Mr Ludlam, in the *Phil. Trans.* vol. lxx. p. 378, &c.

TRANQUILLITY, a place in Sussex county, New-Jersey, 8 miles southerly of Newtown.—*Morse.*

TRANSFORMATION, in geometry, is the changing or reducing of a figure, or of a body, into another of the same area, or the same solidity, but of a different form. As, to transform or reduce a triangle to a square, or a pyramid to a parallelopipedon.

Transformation of Equations, in algebra, is the changing equations into others of a different form, but of equal value. This operation is often necessary, to prepare equations for a more easy solution.

TRANSLATION, in literature, is a matter of so much importance, that no other apology can be made for the very imperfect manner in which it is treated in the *Encyclopædia*, than a candid declaration that it was impossible to enter at all upon the subject within the narrow limits to which we were then restricted by the proprietors of the work. The fundamental laws of translation, which we gave from Dr Campbell of Aberdeen, we believe indeed to be unexceptionable; but the question is, how are these laws to be obeyed?

In order that a translator may be enabled to give a complete transcript of the ideas of the original work, it is almost needless to observe, that he must possess a perfect knowledge of both languages, *viz.* that of his author, and that into which he is to translate; and that he must have a competent acquaintance with the subject of which his author treats. These propositions we consider as self evident; but if any of our readers shall be of a different opinion, we refer them to an *Essay on the Principles of Translation*, published 1797 by Cadell and Davies, London, where they will find our doctrine very clearly illustrated. It may be proper to add, that such a knowledge of the Greek and Latin languages as merely enables a man to read them with ease and entertainment to himself, is by no means sufficient to qualify him for translating every Greek and Latin book, even though it treats of a subject with which he has a general acquaintance. The religious rites and ceremonies of the Greeks and Romans, as well as the radical words of their language, were derived from the East; and he who is an absolute stranger to oriental literature, will be very liable to mistake occasionally the sense of Greek and Roman authors who treat of religious subjects. We could illustrate the truth of this position by quotations from some of the most admired modern translations of the Greek Scriptures, which we have no hesitation to say fall very short of the authorised version in accuracy as well as in elegance. The divines employed by King James

James to tranſlate the Old and New Teſtaments were profoundly ſkilled in the learning, as well as in the languages of the Eaſt; whilſt ſome of thoſe who have preſumed to improve their verſion ſeem not to have poſſeſſed a critical knowledge of the Greek tongue, to have known ſtill leſs of the Hebrew, and to have been abſolute ſtrangers to the dialect ſpoken in Judea in the days of our Saviour, as well as to the manners, cuſtoms, and peculiar opinions of the Jews ſects. Neither metaphyſical acuteneſs, nor the moſt perfect knowledge of the principles of tranſlation in general, will enable a man who is ignorant of theſe things to improve the authoriſed verſion either of the Goſpels or the Epiſtles; for ſuch a man knows not accurately, and therefore cannot give a complete tranſcript of the ideas of the original work.

But ſuppoſing the tranſlator completely qualified with reſpect to knowledge, it becomes a queſtion, whether he may, in any caſe, add to or retrench the ideas of his author? We are ſtrongly inclined to think, that, in no caſe, it is allowable to take ſuch liberties; but the ingenious and elegant eſſayiſt, whoſe work on the principles of tranſlation we muſt always quote with reſpect, is of a different opinion. "To give a general anſwer (ſays he) to this queſtion, I would ſay, that this liberty may be uſed, but with the greateſt caution. It muſt be further obſerved, that the ſuperadded idea ſhall have the moſt neceſſary connection with the original thought, and actually increaſe its force. And, on the other hand, that whenever an idea is cut off by the tranſlator it muſt be only ſuch as is an acceſſory, and not a principle, in the clauſe or ſentence. It muſt likewiſe be confeſſedly redundant, ſo that its retrenchment ſhall not impair or weaken the original thought. Under theſe limitations, a tranſlator may exerciſe his judgment, and aſſume to himſelf, in ſo far, the character of an original writer."

Of the judicious uſe, as he thinks it, of this liberty, the author quotes many examples, of which we ſhall ſelect three, as well calculated to illuſtrate our own ideas of the ſubject.

In the firſt book of the Iliad, Achilles, having reſolved, though indignantly, to give up Briſeis, deſires Petroclus to deliver her to the heralds of Agamemnon:

> Ὡς φατο· Πατροκλος δε φιλω επεπειθεθ' ἑταιρω·
> Εκ δ' αγαγε κλισιης Βρισηιδα καλλιπαρηον,
> Δωκε δ' αγειν· τω δ' αυτις ιτην παρα νηας Αχαιων·
> Ἡ δ' ακεους' ἁμα τοισι γυνη κιεν· *Ilias*, A. 345.

> Patroclus now th' unwilling beauty brought;
> She in ſoft ſorrows, and in penſive thought,
> Paſt ſilent, as the heralds held her hand,
> And oft look'd back, ſlow moving o'er the ſtrand.
> POPE.

Our author thinks, and we heartily agree with him, that the amplification in the three laſt lines of this verſion highly improves the effect of the picture; but we cannot conſider this amplification as a new idea ſuperadded. It was the object of Homer to inform his countrymen, that Briſeis went with the heralds *unwillingly*. This he does by the words ἡ δ' ακεουσ' ἁμα τοισι γυνη κιεν· and it is by no means improbable, that the rhythmical movement of the verſe may have preſented to the ancient Greeks the image of the lady, walking ſlowly and reluctantly along. This image, we are ſure, is not produced by a literal tranſlation of the Greek words into Engliſh; and therefore it was Pope's duty, not to add to the ideas of the original, but, by amplification, to preſent to his own countrymen the picture which Homer, by the ſuperiority of the Greek language and rythm, had preſented to his.

In the ninth book of the Iliad, where Phœnix reminds Achilles of the care he had taken of him while an infant, one circumſtance, extremely mean, and even diſguſting, is found in the original:

> ——— ὁτε δη σ' επ' εμοισιν εγω γουνασσι καθισσας
> Οψου τ' ασαιμι προταμων, και οινον επισχων·
> Πολλακι μοι κατεδευσας επι στηθεσσι χιτωνα,
> Οινου αποβλυζων εν νηπιεη αλεγεινη.

The literal verſion of theſe lines is indeed very groſs: "When I placed you before my knees, I crammed you with meat, and gave you wine, which you often vomited upon my boſom, and ſtained my clothes, in your troubleſome infancy:" but we cannot agree with our author, that the Engliſh reader is obliged to Pope for having altogether ſunk this nauſeous image. What is, or ought to be, our object in reading Homer? If it be merely to delight our ear with ſonorous lines, and pleaſe our fancy with grand or ſplendid images, the tranſlator certainly did right in keeping out of view this diſguſting picture of ſavage life; but when he did ſo, he cannot be ſaid to have given a complete tranſcript of his author's ideas. To pleaſe ourſelves, however, with ſplendid images, is not our only object when ſtudying the works of the ancient poets. Another, and in our opinion a more important object, is to acquire a lively notion of ancient manners; and if ſo, Pope groſsly miſleads the mere Engliſh reader, when, inſtead of the beaſtly image of Homer, he preſents him with the following ſcene, which he may daily meet with in his own family, or in the families of his friends:

> Thy infant breaſt a like affection ſhow'd,
> Still in my arms, an ever pleaſing load;
> Or at my knee, by Phœnix would'ſt thou ſtand,
> No food was grateful but from Phœnix hand:
> I paſs my watchings o'er thy helpleſs years,
> The tender labours, the compliant cares.

This is a picture of the domeſtic manners of Great Britain in the 18th century, and not of Greece in the heroic ages.

In the beginning of the eighth book of the Iliad, Homer puts into the mouth of Jove a very ſtrange ſpeech, ſtuffed with braggart vaunting and ludicrous images. This, as our author obſerves, is far beneath the dignity of the thunderer; but it is only beneath the dignity of the thunderer as our habits and modes of thinking compel *us* to conceive ſuch a being. The thunderer of the Greeks was a notorious adulterer and ſodomite, whoſe moral character ſinks beneath that of the meaneſt of our bravos; and as he had dethroned his father, and waged for ſome time a doubtful war with certain *earthly* giants, it does not appear to us that the boaſting ſpeech which Homer puts into his mouth is at all unſuitable to his acknowledged attributes. But whether it be or not, was not the tranſlator's concern. Homer, when he compoſed it, certainly thought it not unworthy of the thunderer; and whatever Pope's opinion might be, he had

had no right to ſubſtitute his own notions of propriety for thoſe of his author. The mythological tales of the poets, and more eſpecially of Homer and Heſiod, conſtituted, as every one knows, the religious creed of the vulgar Greeks (ſee Polytheism, n° 33. *Encycl.*); and this circumſtance makes it doubly the duty of a tranſlator to give, on ſuch ſubjects, a fair tranſcript of his author's ideas, that the mere Engliſh reader, for whom he writes, may know what the ancients really thought of the objects of their idolatrous worſhip. This Pope has not done in the ſpeech under conſideration; and has therefore, in our opinion, deviated widely from the firſt and moſt important of the three general laws of tranſlation. Johnſon has apologized, we think ſufficiently, for many of Pope's embelliſhments of his author; but he has not attempted to make an apology for ſuch embelliſhments as alter the ſenſe. We cannot indeed conceive a pretence upon which it can ever be allowable in a tranſlator to add to the ideas of his author, to retrench, or to vary them. If he be tranſlating hiſtory, and find his author advancing what he *believes* to be falſe, he may correct him in a note; but he has no right to make one man utter, as his own, the belief or the ſentiments of another, when that belief, and thoſe ſentiments, are *not* his own. If he be tranſlating a work of ſcience, he may likewiſe correct the errors of his author in notes, as Dr Clerke corrected thoſe of Rohault; but no man has a right to give to a Rohault the ſcience of a Newton. The tranſlator of a poem may certainly employ amplification to place in a ſtriking light the images or the ſentiments of the original work; but he muſt not alter thoſe images or ſentiments ſo as to make that appear grand or elegant in the verſion, which is mean or diſguſting in the original. On every occaſion on which he takes ſuch liberties as theſe, he ceaſes to be a tranſlator, and becomes a faithleſs paraphraſt.

The ſecond general law of tranſlation, though certainly leſs important, is perhaps more difficult to be obſerved than the firſt. We have ſtated it in theſe words: (See Translation, *Encycl.*) "The ſtyle and manner of the original ſhould be preſerved in the tranſlation;" but it is obvious that this cannot be done by him who poſſeſſes not ſufficient taſte and judgment to aſcertain with preciſion to what claſs the ſtyle of the original belongs. "If a tranſlator fail in this diſcernment, and want this capacity, let him be ever ſo thoroughly maſter of the ſenſe of his author, he will preſent him through a diſtorting medium, or exhibit him in a garb that is unſuitable to his character." It would obviouſly be very improper to tranſlate the elegantly ſimple language of Cæſar into rounded periods like thoſe of *The Rambler*, or the Orations of Cicero into the language of Swift.

The chief characteriſtic of the hiſtorical ſtyle of the ſacred Scriptures is its ſimplicity; and that ſimplicity is, for the moſt part, well preſerved in the authoriſed verſion. It is, however, loſt in many of the modern verſions. Caſtalio's, for inſtance, though intitled to the praiſe of elegant latinity, and though, in general, faithful to the ſenſe of the original, yet exhibits numberleſs tranſgreſſions of the law which is now under conſideration. Its ſentences are formed in long and intricate periods, in which many ſeparate members are artfully combined; and we obſerve a conſtant endeavour at claſſical phraſeology and ornamented diction, inſtead of the beautiful ſimplicity of the original.

The verſion of the Scriptures by Arias Montanus is, in ſome reſpects, a contraſt to that of Caſtalio. By adopting the literal mode of tranſlation, Arias undoubtedly intended to give as faithful a picture as he could, both of the ſenſe and of the manner of the original. Not attending to the peculiar idioms of the Hebrew, Greek, and Latin tongues, which, in ſome reſpects, are very different from each other, he has, by giving to his Latin the combination and idioms of the two firſt of theſe languages, ſometimes made the ſacred writers talk abſurdly. In Latin, as every ſchool-boy knows, two negatives make an affirmative, whilſt in Greek they add force to the negation. Χωρις εμου ου δυνασθε ουδεν ſignifies, "Without me ye can do nothing," or, "Ye cannot *poſſibly* do any thing;" but Arias has tranſlated the words *ſine me non poteſtis facere nihil, i. e.* "without me ye cannot do nothing," or, "ye *muſt* do ſomething," which is directly contrary to the meaning of our Lord. It is not therefore by tranſlating literally or verbally that we can hope to preſerve the ſtyle and manner of the original.

To expreſs in florid or elevated language the ideas of an author who writes himſelf in a ſimple ſtyle, is not to give in the verſion a juſt picture of the original; but to attempt, for the ſake of verbal accuracy, to introduce into one language the peculiar idioms or conſtruction of another, is ſtill worſe, as in this mode of tranſlation the ſenſe, as well as the manner of the original, is loſt. The rule obviouſly is to uſe, in the verſion, the words and phraſeology which we have reaſon to believe that the author would himſelf have uſed, had he been maſter of the language into which we are tranſlating his ideas. Thus if we are to tranſlate into Engliſh a piece of elegantly ſimple Greek or Latin, we muſt make ourſelves completely maſter of the author's meaning, and, neglecting the Greek or Latin *idioms*, expreſs that meaning in elegantly ſimple Engliſh. We need not add, that when the language of the original is florid or grand, if that ſtyle be ſuited to the ſubject, the language of the tranſlation ſhould be florid or grand likewiſe; but care muſt always be taken that perſpicuity be not ſacrificed to ambitious ornaments of any kind; for ornaments which obſcure the ſenſe are worſe than uſeleſs.

If theſe reflections be juſt, it is obvious that a poem cannot be properly tranſlated into proſe. The mere ſenſe may doubtleſs be thus transferred from one language into another, as has generally been done by Macpherſon in his hobbling verſion of the Iliad, and perhaps more completely by a late tranſlator of Anacreon; but in ſuch a verſion, the ſtyle and manner of the original muſt neceſſarily be loſt. Of this the following accurate proſe tranſlation of Anacreon's ninth ode (on a dove) is a ſtriking inſtance:

"O lovely Pigeon! whence, whence do you fly? Whence, ſpeeding through the air, do you breathe, and diſtil ſo many perfumes? Who is your maſter? For it concerns me to know. 'Anacreon ſent me to a youth, —to Bathyllus, at preſent the prince, and diſpoſing of all things. Venus ſold me, receiving a little hymn in return. And I ſerve Anacreon in ſuch tranſactions as theſe: and now I carry his letters, ſuch as you ſee: and he affirms that he will immediately make me free.

But

But I will remain a servant with him although he may dismiss me: For wherefore does it behove me to fly, both over mountains, and fields, and to perch on trees, devouring some rustic food? Now indeed I eat bread, snatching it from the hands of Anacreon himself; and he gives to me the wine to drink which he drinks before me; and having drunk, I perhaps may dance, and cover my master with my wings; then going to rest, I sleep upon the lute itself. You have it all;—begone: you have made me more talkative, O mortal! than even a jay*."

he Odes Anacreon, slated English e, printed t York, 6.

How inferior is the general effect of this piece of prose to that of the well-known poetical versions of Addison and Johnson? and yet the mere *ideas* of the original are perhaps more faithfully transcribed by this anonymous writer than by either of those elegant translators. The emotions indeed excited by the original are not here brought into view.

The third general law of translation is so nearly allied to the second, that we have very few directions to give for the observation of it. He who, in his version, preserves the style and manner of the original, as we have endeavoured to shew that they *ought* to be preserved, will, of course, give to the translation the ease of original composition. The principal difficulty that he has to encounter in this part of his task, will occur in the translating of idiomatical and proverbial phrases. Hardly any two languages are constructed precisely in the same way; and when the structure of the English language is compared with that of the Greek and Latin, a remarkable difference between the ancient and modern tongues is found to pervade the whole. This must occasion very considerable difficulty; but it is a difficulty which will be removed by a due observance of the former law, which directs the translator to make his author speak English in such a style to Englishmen as he spoke his own tongue to his own countrymen, and of course to use the English idiom with English words. But what is to be done with those proverbial phrases of which every language has a large collection, and which allude to local customs and manners?

The ingenious author of the Essay so often quoted, very properly observes, in answer to this question, that the translation is perfect when the translator employs, in his own language, an idiomatic phrase corresponding to that of the original. "It is not (says he) possible perhaps to produce a happier instance of translation by corresponding idioms, than Sterne has given* in the translation of Slaukenbergius's tale. *Nihil me penitet hujus nasi*, quoth Pamphagus; that is, "My nose has been the making of me." *Nec est cur pœniteat*; that is, "How the deuce should such a nose fail?" *Miles peregrini in faciem suspexit!* "The centinel looked into the stranger's face. Never saw such a nose in his life!"

ristram ndy.

"As there is nothing (continues our author) which so much conduces both to the ease and spirit of composition as a happy use of idiomatic phrases, there is nothing which a translator, who has a moderate command of his own language, is so apt to carry to an extreme." Of this he gives many striking examples from Echard's translation of Terence and Plautus, for which we must refer the reader to the Essay itself. He observes, likewise, that in the use of idiomatic phrases, a translator frequently forgets both the country of his original author, and the age in which he wrote; and while he makes a Greek or Roman speak French or English, he unwittingly puts into his mouth allusions to the manners of modern France or England. This, to use a phrase borrowed from painting, may be termed an offence against the *costume*. The proverbial expression βατραχῳ ὑδωρ, in Theocritus, is of similar import with the English proverb, *to carry coals to Newcastle*; and the Scotch, *to drive salt to Dysart*; but it would be a gross impropriety to use either of these expressions in the translation of an ancient classic. Of such improprieties our author points out many instances both in French and English translations of the classics; and he might have increased the number by quotations from Blackwell's Memoirs of the Court of Augustus, where, instead of Roman senators and their wives, we meet with modern gentlemen and ladies, with *secretaries at war*, *paymasters*, *commissary generals*, and *lord high admirals*. It is true the memoirs of the court of Augustus is no translation; but with respect to costume, it is necessarily subject to the laws of translation.

Offences against costume are often committed by the use of improper words as well as of improper phrases. To introduce into dignified and solemn composition words associated with mean and ludicrous subjects, is equally a fault in an original author and in a translator; and it is obviously improper, in the translation of works of very high antiquity, to make use of words which have but lately been admitted into the language of the translator. Faults of this kind are very frequent in Dr Geddes's translation of the Bible, as when the *passover* is called the *skipover*; the tabernacle of the congregation, the *convention-tent*; and a burnt-offering, a *holocaust*. The first of these expressions presents to the imagination an image profanely ludicrous; the second, brings into our view the French Convention, which, we suspect, occupied no small portion of the Doctor's thoughts, when they should have been wholly employed on the sacred text; and the word *holocaust*, which must be unintelligible to the mere English reader, is, in the mind of every man of letters, closely associated with the abominable rites performed at the sacrifices of the ancient heathens. But it is needless to point out faults of this kind in a work which is open to more serious objections, and which, we trust, shall never be generally read. We are sorry that truth compels us to say, that the novel expressions introduced by Dr Campbell into his version of the gospels—such as *confluence* for multitude, and *reign* for kingdom—are, to say the best of them, no improvements of the authorised version. We will not rank them with Dr Geddes's innovations, because we will not class the great author of the *Dissertation on Miracles* with a paradoxical Christian of no communion; but we do not think that Dr Campbell's laurels were freshened on his brow by the translation of the Gospels.

We shall conclude this article with the following reflections, taken from the Essay which has been so often quoted:

"If the order in which we have classed the three general laws of translation be their just and natural arrangement, which, we presume, will hardly be denied, it follows, that, in every case where it is necessary to make a sacrifice of one of these laws to another, a due regard ought to be paid to their rank and comparative importance. When the genius of the original language differs much from that of the translation, it is often necessary

ceſſary to depart from the author's manner in order to convey a faithful picture of his ſenſe; but it would be highly prepoſterous to depart, in any caſe, from the ſenſe, for the ſake of imitating the manner. Equally improper would it be, to ſacrifice either the ſenſe or manner of the original, if theſe can be preſerved conſiſtently with purity of expreſſion, to a fancied eaſe or ſuperior gracefulneſs of compoſition; and it is certain that the ſenſe may always be preſerved, though to purity of expreſſion the manner of the original muſt ſometimes be ſacrificed."

TRAP, a village in Talbot county, Maryland; about 6 miles S. E. of Oxford.—*Morse.*

TRAP, *The*, a village of Pennſylvania, in Montgomery county, having about a dozen houſes, and a German Lutheran and Calviniſt church united. It is 9 miles from Morriſtown, 11 from Pottſgrove, and 26 from Philadelphia.—*ib.*

TRAP, a village of Maryland, in Somerſet county, ſituated at the head of Wicomico Creek, a branch of the river Wicomico, 7 miles ſouth-weſt of Saliſbury, and 6 north of Princeſs Ann.—*ib.*

TRAPEZOID, ſometimes denotes a trapezium that has two of its ſides parallel to each other; and ſometimes an irregular ſolid figure, having four ſides not parallel to each other.

TRAPTOWN, a village of Maryland, in Frederick county, ſituated on Cotoctin Creek, between the South and Cotoctin Mountains, and 7 miles ſouth-weſterly of Fredericktown.—*Morse.*

TRAVERSE, in gunnery, is the turning a piece of ordnance about, as upon a centre, to make it point in any particular direction.

TRAVERSE, in fortification, denotes a trench with a little parapet, ſometimes two, one on each ſide, to ſerve as a cover from the enemy that might come in flank.

TRAVERSE, in a wet foſs, is a ſort of gallery, made by throwing ſauciſſons, joiſts, faſcines, ſtones, earth, &c. into the foſs, oppoſite the place where the miner is to be put, in order to fill up the ditch, and make a paſſage over it.

TRAVERSE alſo denotes a wall of earth, or ſtone, raiſed acroſs a work, to ſtop the ſhot from rolling along it.

TRAVERSE alſo ſometimes ſignifies any retrenchment, or line fortified with faſcines, barrels, or bags of earth, or gabions.

TRAVERSE *Bay, Great*, lies on the N. E. corner of Lake Michigan. It has a narrow entrance, and ſets up into the land ſouth-eaſtward, and receives Traverſe river from the E.—*Morse.*

TRAVESTY, or burleſque tranſlation, is a ſpecies of writing which, as it partakes, in a great degree, of original compoſition, is not to be meaſured by the laws of ſerious tranſlation. It conveys neither a juſt picture of the ſentiments, nor a faithful repreſentation of the ſtyle and manner of the original; but pleaſes itſelf in exhibiting a ludicrous caricatura of both. It diſplays an overcharged and groteſque reſemblance, and excites our riſible emotions by the incongruous aſſociation of dignity and meanneſs, wiſdom and abſurdity. This aſſociation forms equally the baſis of traveſty and of ludicrous parody, from which it is no otherwiſe diſtinguiſhed than by its aſſuming a different language from the original. In order that the mimickry may be underſtood, it is neceſſary that the writer chooſe, for the exerciſe of his talents, a work that is well known, and of great reputation. Whether that reputation is deſerved or unjuſt, the work may be equally the ſubject of burleſque imitation. If it has been the ſubject of general, but undeſerved praiſe, a parody or a traveſty is then a fair ſatire on the falſe taſte of the original author and his admirers, and we are pleaſed to ſee both become the objects of a juſt caſtigation. The *Rehearſal*, *Tom Thumb*, and *Crononhotonthologos*, which exhibit ludicrous parodies of paſſages from the favourite dramatic writers of the times, convey a great deal of juſt and uſeful criticiſm. If the original is a work of real excellence, the traveſty or parody detracts nothing from its merit, nor robs the author of the ſmalleſt portion of his juſt praiſe. We laugh at the aſſociation of dignity and meanneſs; but the former remains the excluſive property of the original, the latter belongs ſolely to the copy. We give due praiſe to the mimical powers of the imitator, and are delighted to ſee how ingeniouſly he can elicit ſubjects of mirth and ridicule from what is grave, dignified, pathetic, or ſublime.

But this ſpecies of compoſition pleaſes only in a ſhort ſpecimen. We cannot bear a lengthened work in traveſty. The incongruous aſſociation of dignity and meanneſs excites riſibility chiefly from its being unexpected. Cotton's and Scarron's Virgil entertain but for a few pages: the compoſition ſoon becomes tedious, and at length diſguſting. We laugh at a ſhort exhibition of buffoonery; but we cannot endure a man who, with good talents, is conſtantly playing the fool.

TREACLE (ſee *Encycl.*) or MELASSES, is a ſubſtance very wholeſome, but of a taſte diſagreeably ſweet. Methods have accordingly been propoſed for purifying it, ſo that it may, on many occaſions, ſupply the place of refined ſugar, which has long been at a price which a great number of poor perſons cannot afford to pay for what muſt now be conſidered as a neceſſary of life. The following is the proceſs for purifying treacle, given by the M. Cadet (Devaux) in the *Feuille du Cultivateur*, founded upon experiments made by Mr Lowitz of Peterſburgh:

Take of treacle 24 lbs. of water 24 lbs. of charcoal, thoroughly burnt, 6 lbs. Bruiſe the charcoal groſsly, mix the three ſubſtances in a caldron, and let the mixture boil gently upon a clear wood fire. After it has boiled for half an hour, pour the liquor through a ſtraining-bag, and then replace it upon the fire, that the ſuperfluous water may be evaporated, and that the treacle may be brought to its original conſiſtence. There is little or no loſs by this operation, as 24 lbs. of treacle give nearly the ſame quantity of ſyrup.

This proceſs has been repeated in the large way, and has ſucceeded: the treacle is ſenſibly ameliorated, ſo that it may be uſed for many diſhes; nevertheleſs, thoſe with milk, and the fine or aromatic *liqueurs*, are not near ſo good as with ſugar.

TREADHAVEN *Creek*, a ſmall branch of Choptank river.—*Morse.*

TREASURY *Iſlands*, form a part of Mr Shortland's *New-Georgia*, (Surville's Archipelago of the Arſacides) lying from 6 38 to 7 30 S. lat. and from 155 34 to 156 E. long. from Greenwich.—*ib.*

TREBISOND, a large, populous, and ſtrong town of Turkey in Aſia, in the province of Jenich, with a Greek archbiſhop's ſee, a harbour, and a caſtle. It is ſeated

seated at the foot of a very steep hill. The walls are square and high, with battlements; and are built with the ruins of ancient structures, on which are inscriptions not legible. The town is not populous; for there are more woods and gardens in it than houses, and these but one story high. The castle is seated on a flat rock, with ditches cut therein. The harbour is at the east end of the town, and the mole built by the Genoese is almost destroyed. It stands on the Black Sea, 104 miles north-west of Erzerum, and 440 east of Constantinople. E. Lon. 40° 25′ N. lat. 40° 45′.

TREE. Under this title (*Encycl.*) we gave an account of the method recommended by Messrs Forsyth and Hitt for curing injuries and defects in trees. The actual cautery is employed in Cevennes, and in the department de l'Allier in France, for stopping the progress of rottenness in large trees. When they perceive that this very common and destructive disease begins to make some progress in the chesnut tree, by excavating its trunk, they collect heath, and other combustible vegetables, and burn them in the very cavity, till the surface is completely converted into a coal. It seldom happens that the tree perishes by the effect of this operation, and it is always found that this remedy suspends the progress of the decay. It is practised in the same manner, and with similar success, on the white oak. When we compare the effects of the actual cautery on the animal system, in similar diseases, a new resemblance is seen between the diseases which affect the organic beings of both kingdoms, as well as between the remedies by which they may be opposed.—*Nicholson's Journal.*

TRENCHE MONT *River*, a small river of the island of St John's, in the Gulf of St Lawrence. It empties into the sea 3 or 4 leagues to the westward of the eastern extremity of the island.—*Morse.*

TRECOTHIC, a township in Grafton county, New-Hampshire, incorporated in 1769.—*ib.*

TRENT, a small river of N. Carolina, which falls into Neus river, at Newbern. It is navigable for sea vessels, 12 miles above the town, and for boats 20.—*ib.*

TRENTON, is one of the largest towns in New-Jersey, and the metropolis of the state, situated in Hunterdon county, on the E. side of Delaware river, opposite the falls, and nearly in the centre of the state from N. to S. The river is not navigable above these falls, except for boats which will carry from 500 to 700 bushels of wheat. This town, with Lamberton, which joins it on the south, contains between 200 and 300 houses, and about 2,000 inhabitants. Here the legislature statedly meets, the supreme court sits, and most of the public offices are kept. The inhabitants have lately erected a handsome court-house, 100 feet by 30, with a semi-hexagon at each end, over which is a balustrade. Here are also a church for Episcopalians, one for Presbyterians, one for Methodists, and a Quaker meeting-house. In the neighbourhood of this pleasant town, are a great many gentlemen's seats, finely situated on the banks of the Delaware, and ornamented with taste and elegance. Here is a flourishing academy. It is 12 miles S. W. of Princeton, 30 from Brunswick, and 30 N. E. of Philadelphia. N. lat. 40 15, W. long. 74 15.—*ib.*

Trenton, a small post-town of the District of Maine, Hancock county, 12 miles W. by S. of Sullivan, 31 N. E. by E. of Penobscot, 286 N. E. of Boston, and 633 N. E. of Philadelphia. This town is near Desert Island; and in a part of it called *The Narrows* were about 40 families in 1796.—*ib.*

Trenton, the chief town of Jones' county, N. Carolina, situated on the S. side of Trent river. It contains but few houses, besides the court-house and gaol. It is 521 miles from Philadelphia.—*ib.*

TREPASSI *Bay*, or *Trespasses Bay*, and *Harbour*, on the south side of Newfoundland Island, near the S. E. part, and about 21 miles to the N. westward of Cape Race, the S. E. point of the island. The harbour is large, well secured, and the ground good to anchor in.—*ib.*

TRIANGLE, Arithmetical, a kind of numeral triangle, or triangle of numbers, being a table of certain numbers disposed in form of a triangle. It was so called by Pascal; but he was not the inventor of this table, as some writers have imagined, its properties having been treated of by other authors some centuries before him, as is shewn in Dr Hutton's Mathematical Tracts, vol. i. p. 69. &c.

The form of the triangle is as follows:

1					
1	1				
1	2	1			
1	3	3	1		
1	4	6	4	1	
1	5	10	10	5	1
1	6	15	20	&c.	
1	7	21	&c.		
1	8	&c.			
1	9				

And it is constructed by adding always the last two numbers of the next two preceding columns together, to give the next succeeding column of numbers.

The first vertical column consists of units; the second, a series of the natural numbers 1, 2, 3, 4, 5, &c.; the third, a series of triangular numbers 1, 3, 6, 10, &c.; the fourth, a series of pyramidal numbers, &c. The oblique diagonal rows, descending from left to right, are also the same as the vertical columns. And the numbers taken on the horizontal lines are the co-efficients of the different powers of a binomial. Many other properties and uses of these numbers have been delivered by various authors, as may be seen in the Introduction to Hutton's Mathematical Tables, pages 7, 8, 75, 76, 77, 89, second edition.

Triangle *Island*, a small island, one of the Bahamas. N. lat. 20 51, W. long. 69 53.—*Morse.*

Triangle *Shoals*, lie to the westward of the peninsula of Yucatan, near the E. shore of the Bay of Campeachy, nearly W. of Cape Condecedo. N. lat. 17 5, W. long. 111 59.—*ib.*

TRIANGULAR Compasses, are such as have three legs or feet, by which any triangle or three points, may be taken off at once. These are very useful in the construction of maps, globes, &c.

Triangular Numbers, are a kind of polygonal numbers; being the sums of arithmetical progressions, which have 1 for the common difference of their terms.

Thus, from these arithmeticals 1 2 3 4 5 6,
are formed the triangular numbers 1 3 6 10 15 21,
or the third column of the arithmetical triangle above-mentioned.

The sum of any number n of the terms of the triangular numbers, 1, 3, 6, 10, &c. is =

$$\frac{n^3}{6}+\frac{n^2}{2}+\frac{n}{3}, \text{ or } \frac{n}{1}\times\frac{n+1}{2}\times\frac{n+2}{3}$$

which is alfo equal to the number of fhot in a triangular pile of balls, the number of rows, or the number in each fide of the bafe, being n.

The fum of the reciprocals of the triangular feries, infinitely continued, is equal to 2; viz.

$$1+\tfrac{1}{3}+\tfrac{1}{6}+\tfrac{1}{10}+\tfrac{1}{15}, \&c. = 2.$$

For the rationale and management of thefe numbers, fee *Malcolm's Arith.* book 5. ch. 2.; and *Simpfon's Algeb.* fec. 15.

TRIESTE, a fmall, but ftrong and ancient feaport of Italy, in Iftria, on the gulph of Venice, with a bifhop's fee. It is beautifully fituated on the fide of a hill, about which the vineyards form a femicircle. The ftreets are narrow; but there is a large fquare, where they keep the annual fair. The harbour is fpacious, but not good; becaufe it is open to the W. and S. W. winds. The inhabitants have a good trade in falt, oil, almonds, iron, &c. brought from Laubach; and they make good wines. The cathedral, and the late Jefuits church, are the two beft buildings. It belongs to the Houfe of Auftria, and is eight miles north of Capo d'Iftria, and 80 north-eaft of Venice. E. Long. 14 4. N. Lat. 45. 56.

TRIESTE *Bay*, on the coaft of Terra Firma, is nearly due fouth from Bonair Ifland, one of the Little Antilles, to the eaft of Curaffou Ifland.—*Morse.*

TRIESTE *Ifland*, a fmall ifland at the bottom of the Gulf of Campeachy, weftward of Port-Royal Ifland, about 3 leagues from E. to W. The creek which feparates it from Port-Royal Ifland is fcarcely broad enough to admit a canoe. Good frefh water will be got by digging 5 or 6 feet deep in the falt fand; at a lefs depth it is brackifh and falt, and at a greater depth than 6 feet it is falt again.—*ib.*

TRINIDAD, a fmall ifland in the S. Atlantic Ocean, due E off Spiritu Santo, in Brazil. S. lat. 20 30, W. long. 41 20. It is alfo called Trinity.—*ib.*

TRINADAD, or *Trinidada Ifland*, near the coaft of Terra Firma, at the north part of S. America. It partly forms the Gulf of Paria, or Bocca del Drago, and is much larger than any other upon the coaft. It is 36 leagues in length, and 18 or 20 in breadth, but the climate is rather unhealthy, and little of it is cleared. The current fets fo ftrong along the coaft from E. to W. as to render moft of its bays and harbours ufelefs. It produces fugar, fine tobacco, indigo, ginger, a variety of fruit, fome cotton and Indian corn. It was taken by Sir Walter Raleigh, in 1595, and by the French in 1676, who plundered the ifland, and extorted money from the inhabitants. It was captured by the Britifh in February, 1797. It is fituated between 59 and 62 W. long. and in 10 N. lat. The N. E. point lies in lat. 10 28 N. and long. 59 37 W. The chief town is St Jofeph.—*ib.*

TRINIDAD, LA, a town of Mexico, in the province of Guatimala, on the banks of the river Belen, 12 miles from the fea; but the road is almoft impaffable by land. It is 70 miles S. E. of Guatimala, and 24 eaft of La Conception. N. lat. 13, W. long. 91 40.—*ib.*

TRINIDAD, LA, on the north coaft of the Ifthmus of Darien, lies eaftward of Bocca del Toro, and fome clufters of fmall iflands, and S. W. of Porto Bello and Fort Chagre. N. lat. 8 30, W. long. 81 30.—*ib.*

TRINIDAD, or *La Sonfonate Port*, a town on a bay of the Pacific Ocean, about 65 miles S. E. of Petapa, and 162 from the town of Guatimala. All the goods that are fent from Peru and Mexico to Acaxatla, about 12 miles from it, are brought to this port. It is 9 miles from the town to the harbour which is much frequented, and is a place of great trade; being the neareft landing to Guatimala for fhips that come from Peru, Panama, and Mexico.—*ib.*

TRINIDAD, LA, one of the fea-ports on the fouth part of the ifland of Cuba, in the Weft-Indies; fituated N. W. from the weft end of the groupe of iflands called Jardin de la Reyna. N. lat. 21 40, W. long. 80 50.—*ib.*

TRINIDAD, LA, an open town of Veragua, and audience of Mexico, in N. America.—*ib.*

TRINIDAD *Channel*, has the ifland of Tobago on the N. W. and that of Trinidad on the fouth.—*ib.*

TRINIDAD, or *Trinity*, a town of New-Granada, and Terra Firma, in S. America, about 23 miles N. E. of St Fe.—*ib.*

TRINITARIANS (Order of), was inftituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha and Felix de Valois. His Holinefs gave them permiffion to eftablifh this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them as a habit a white gown, ornamented with a red and blue crofs. After the death of the two founders, Pope Honorious III. continued the order; and their rule was approved by his fucceffor Clement IV. in 1367. At firft they were not permitted to eat flefh; and when they travelled, were to ride only upon affes. But their rule was corrected and mitigated by the bifhop of Paris, and the abbots of St Victor and St Genevieve, who allowed them to eat any kind of food, and to ufe horfes. This order poffeffed, at one time, about 250 convents in 13 different provinces: fix of which were in France; namely, France, Normandy, Picardy, Champaine, Languedoc, and Provence; three in Spain, viz. New Caftile, Old Caftile, and Arragon; one in Italy, and one in Portugal. There was formerly the province of England, where this order had 43 houfes; that of Scotland, where it had nine; and that of Ireland, where it had 52; befides a great number of monafteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerfroy in France was head of the order. It is impoffible for us to fay what is now the ftate of the order, which can have no vifible exiftence in France, and is probably fuppreffed even in Italy.

TRINITY *Bay*, on the eaft fide of Newfoundland Ifland, between lat. 47 53 30, and 48 37 N.—*Morse.*

TRINITY *Port*, a large bay of Martinico Ifland, in the Weft-Indies, formed on the fouth-eaft by Point Caravelle.—*ib.*

TRINITY *Ifle* lies near the coaft of Patagonia, in S. America, eaftward of York Iflands. S. lat. 50 37.—*ib.*

TRINITY *Ifle*, the north-eafternmoft of the fmall iflands on the fouth-eaft coaft of the peninfula of Alafka, on the N. W. coaft of N. America, N. E. of Foggy Iflands.—*ib.*

TRIO, a cape on the coaft of Brazil, S. America.—*ib.*

TRIONES, in aftronomy, a fort of conftellation, or assemblage of seven stars in the Ursa Major, popularly called *Charles's Wain.*—From the *septem triones* the north pole takes the denomination *septentrio*.

TRIPOLI of Syria is, according to Mr Browne, by no means so populous a place as we were led to represent it in the *Encyclopædia*. It is indeed, he says, a city of some extent, situated about a mile and a half from the sea; but instead of sixty, he estimates its population at about sixteen thousand. The air is rendered unwholesome by much stagnant water. The town is placed on a slight elevation, the length considerably exceeding the breadth. On the highest ground, to the south, is the castle, formerly possessed by the earls of Tripoli; it is large and strong. Hence is visible a part of mount Libanus, the summit of which is covered with snow. The gardens in the vicinity are rich in mulberry and other fruit trees. The city is well built, and most of the streets are paved.

Here is found a number of Mohammedan merchants, some of the richest and most respectable in the empire. Silk is the chief article of commerce.

The *miri*, or fixed public revenue paid by Tripoli to Constantinople, is only about L. 1000 Sterling, 20 purses, a-year. Syria at present contains only four Pashaliks, Damascus, Aleppo, Acré, and Tripoli; the last of which is the smallest in territory and power. Our author observed no antiquities at Tripoli; but the country round it is noted for producing the best tobacco in Syria.

TRISECTION, the dividing a thing into three equal parts. The term is chiefly used in geometry, for the division of an angle into three equal parts. The *trisection of an angle* geometrically, is one of those great problems, whose solution has been so much sought for by mathematicians for 2000 years past; being, in this respect, on a footing with the famous quadrature of the circle, and the duplicature of the cube.

TRISTAN d'Acunha, the largest of three islands which were visited by Lord Macartney and his suit on the 31st of December 1792. The other two are distinguished by the names of *Inaccessible* and *Nightingale* islands. "Inaccessible (as Sir Erasmus Gower observed) seems to deserve that name, being a high, bluff, as well as apparently barren plain, about nine miles in circumference, and has a very forbidding appearance. There is a high rock detached from it at the south end. Its latitude is 37° 19′ south; its longitude 11° 50′ west from Greenwich. This rude looking spot may be seen at 12 or 14 leagues distance. Nightingale island is irregular in its form, with a hollow in the middle, and is about seven or eight miles in circumference, with small rocky isles at its southern extremity. It is described as having anchorage on the north-east side. Its latitude is 37° 29′ south; and longitude 11° 48′ west from Greenwich. It may be seen at seven or eight leagues distance. The largest of these three islands, which comparatively may be called the great isle of *Tristan d'Acunha*, is very high, and may be seen at 25 leagues distance. It seems not to exceed in circumference 15 miles. A part of the island towards the north rises perpendicularly from the sea to a height apparently of a thousand feet or more. A level then commences, forming what among seamen is termed *table land*, and extending towards the centre of the island; from whence a conical mountain rises, not unlike in appearance to the Peak of Teneriffe, as seen from the bay of Santa Cruz. Boats were sent to sound and to examine the shore for a convenient place to land and water. In consequence of their report, the Lion (a ship of 64 guns) stood in, and came to anchor in the evening on the north side, in 30 fathoms water, one mile from the shore; the bottom black sand with slime; a small rock, off the west point, bearing south-west by south, just open with the western extremity of the island; a cascade, or fall of water, emptying itself upon the beach, south by east. All the shore, from the southern point to the eastern extremity, appears to be clear of danger, and steep, except the west point, where there are breakers about two cables length, or near 500 yards from the shore. The ship, when anchored, was overshadowed by the dark mass of that portion of the island whose sides seemed to rise, like a moss-grown wall, immediately from the ocean. On the right the elevation was less rapid, and between the rising part and the sea was left a flat, of some extent, covered with sedge-grass, interspersed with small shrubs, which, being perfectly green, looked from the ship like a pleasant meadow, watered by a stream that fell, afterwards, from its banks upon the beach. The officers, who went ashore, reported, that the casks might be filled with fresh water by means of a long hose, without moving them from the boats. The landing place thereabouts was also described as being safe, and superior to any other that had been examined. From the plain, the land rose gradually towards the central mountain, in ridges covered with trees of a moderate size and height. The coast abounded with sea lions and seals, penguins and albatrosses. One of the latter was brought on board, his wings measuring ten feet from tip to tip; but others are said to have been found much larger. The coast was covered with a broad sea-weed, several fathoms long, and deservedly by naturalists termed *gigantic fucus*. Some good fish was caught with the hook and line.

"The accident of a sudden gust, by which the anchor was in a few hours driven from its hold, and the ship forced out to sea, prevented the island from being explored, as was intended. It is probable that had the Lion anchored in 20, instead of 30 fathoms water, the anchor would have held firmly. Some advantage was obtained, however, from coming to this place. The just position of those islands, in respect to their longitude, was ascertained, by the mean of several time-pieces, to be about two degrees to the eastward of the place where they are laid down in charts, taken from observations made at a period when the instruments for this purpose were less accurate than at present. The spot where the Lion anchored was determined, by good meridional observations, and by accurate time-pieces, to be 37° 6′ south latitude, and 11° 43′ west longitude from Greenwich. The compass had seven degrees of variation westward from the pole. Fahrenheit's thermometer stood at 67 degrees. It was useful also to have ascertained, that a safe anchorage, and plenty of good water, were to be found here. These islands are certainly worthy of a more particular inquiry; for they are not 50 leagues from the general track of vessels bound to China, and to the coast of Coromandel, by the outer passage. In war time, an excellent rendezvous might be settled there, for ships that wanted no other supply but that of water. When circumstances require

require particular dispatch, it is practicable to come from England to Tristan d'Acunha without stopping in the way, and afterwards to the end of the voyage to India or China."

These islands are separated by a space of about fifteen hundred miles from any land to the westward or northward of them. They are situated in that part of the southern hemisphere, in the neighbourhood of which a continent, to balance the quantity of land in the northern hemisphere, was once expected to be found, but where it has been since discovered that there is none. Of what extent, however, the bases of these islands are under the surface of the sea, cannot be ascertained; or whether they may, or may not, be sufficient to make up for the defect of land appearing above water. Navigators report, that to the eastward of them are other small islands, differing not much in latitude, such as Gough and Alvarez islands, and the Marsouines; as well as extensive shoals, lying due south of the most southerly point of Africa, and extending easterly several degrees. That all these together form a chain, some of subaqueous, and some of superaqueous mountains, but all connected by their roots, is perhaps a conjecture less improbable, than that they should separately arise, like tall columns, from the vast abyss.

A settlement in Tristan d'Acunha is known to have been twice in the contemplation of adventurers, but not as yet to have been carried into execution. One had the project of rendering it a mart for the change of the light manufactures of Hindostan, suited to hot climes, for the silver of the Spanish settlements in South America; in the route between which places it is conveniently situated. The other plan meant is only as a suitable spot for drying and preparing the furs of sea lions and seals, and for extracting the spermaceti of the white or long nosed whale, and the whale-bone and oil of the black species. Whales of every kind were seen sporting about Tristan d'Acunha, particularly near the setting of the sun; and the sword fish likewise made its appearance occasionally.—*Sir George Staunton's Account of the Embassy to China.*

TRISTO, a bay on the north coast of S. America, is W. S. W. of the river Turiano. It has good anchorage and is well sheltered from the swell of the sea. —*Morse.*

TRITON, in zoology, a genus belonging to the order of vermes mollusca. The body is oblong; the tongue is spiral; it has twelve tentacula, six on each side, the hindmost ones having claws like a crab. There is but one species, found in holes of rocks about the shore.

TRIVIGILLO *Bay*, in the Gulf of Honduras, or south shore of the Gulf of Mexico, is within the Island of Pines. Dulce river lies a little to the west.—*Morse.*

TROCADIE, a small island on the N. coast of the Island of St John's, lying off the mouth of Shimene Port, and in the Gulf of St Lawrence.—*ib.*

TROIS *Rivieres*, a bay at the east end of the abovementioned Island of St John's, and west of Cape Breton Island. Three streams fall into it from different directions; hence its name. N. lat. 46 5, W. long. 62 15.—*ib.*

Trois *Rivieres*, or the *Three Rivers*, or *Treble River*, a town of Lower Canada, settled by the French in 1610; and is so called from the junction of three waters a little below the town where they fall into the river St Lawrence. The town stands on the northern bank of the St Lawrence, at that part of the river called Lake St Pierre. It is but thinly inhabited; is commodiously situated for the fur trade, and was formerly the seat of the French government, and the grand mart to which the natives resorted. It is pleasantly situated in a fertile country, about 50 miles south-west of Quebec. The inhabitants are mostly rich, and have elegant, well furnished houses, and the country round wears a fine appearance. N. lat. 46 51, W. long. 75 15.—*ib.*

TROMPEAUR, *Cape*, *del Enganna*, or *False Cape*, is the easternmost point, of the island of St Domingo. N. lat. 18 25, W. long. from Paris 71.—*ib.*

TROPIC *Keys*, are small islands or rocks, on the north of Crab Island, and off the east coast of Porto Rico Island. A number of tropic birds breed here, which are a species never seen but between the tropics. —*ib.*

TROQUOES, a bay at the southern extremity of the eastern part of Lake Huron, separated from Matchudoch Bay on the N. E. by a broad promontory.—*ib.*

TROQUQUA, an island on the north coast of S. America, in the mouth of a small bay near Cape Seco, a short way S. E. from the east point of the bay or river Taratura.—*ib.*

TROTTER (Mrs Catharine), was the daughter of Captain David Trotter, a Scotch gentleman. He was a commander in the royal navy in the reign of Charles II. and at his death left two daughters, the youngest of whom, Catharine, our celebrated author, was born in London, August 1679. She gave early marks of her genius; and learned to write, and also made herself mistress of the French language, by her own application and diligence, without any instructor; but she had some assistance in the study of the Latin grammar and logic, of which latter she drew up an abstract for her own use. The most serious and important subjects, and especially religion, soon engaged her attention.—But notwithstanding her education, her intimacy with several families of distinction of the Romish persuasion, exposed her, while very young, to impressions in favour of that church; which not being removed by her conferences with some eminent and learned members of the church of England, she embraced the Romish communion, in which she continued till the year 1707. In 1695, she produced a tragedy called *Agnes de Castro*, which was acted at the theatre-royal when she was only in her 17th year. The reputation of this performance, and the verses which she addressed to Mr Congreve upon his Mourning Bride, in 1697, were probably the foundation of her acquaintance with that celebrated writer. Her second tragedy, *Fatal Friendship*, was acted in 1698, at the new theatre in Lincoln's-Inn-Fields. This tragedy met with great applause, and is still thought the most perfect of her dramatic performances. Her dramatic talents not being confined to tragedy, she brought upon the stage, in 1701, a comedy called *Love at a loss*, or *Most votes carry it*. In the same year she gave the public her third tragedy, entitled the *Unhappy Penitent*, acted at the theatre-royal in Drury-lane. But poetry and dramatic writing did not so far engross the thoughts of our author but that she sometimes turned them to subjects of a very different nature; and distinguished herself in an extraordinary manner

manner in defence of Mr Locke's writings; a female metaphyfician being a remarkable phenomenon in the republic of letters.

She returned to the exercife of her dramatic genius in 1703, and fixed upon the revolution of Sweden, under Guftavus Erickfon, for the fubject of a tragedy. This tragedy was acted, in 1706, at the Queen's theatre in the Hay-Market. In 1707, her doubts concerning the Romifh religion, which fhe had fo many years profeffed, having led her to a thorough examination of the grounds of it, by confulting the beft books on both fides of the queftion, and advifing with men of the beft judgment, the refult was a conviction of the falfenefs of the pretenfions of that church, and a return to that of England, to which fhe adhered during the remainder of her life. In 1708, fhe was married to the Rev. Mr Cockburn, then curate of St Dunftan's in Fleet-ftreet, but he afterwards obtained the living of Long-Horfeley, near Morpeth in Northumberland. He was a man of confiderable abilities; and, among feveral other things, wrote an account of the Mofaic Deluge, which was much approved by the learned.

Mrs Cockburn's remarks upon fome writers in the controverfy concerning the foundation of moral duty and moral obligation, were introduced to the world, in Auguft 1743, in the Literary Journal, intitled *The Hiftory of the Works of the Learned*. The ftrength, clearnefs, and vivacity fhewn in her remarks upon the moft abftract and perplexed queftions, immediately raifed the curiofity of all good judges about the concealed writer; and their admiration was greatly increafed when her fex and advanced age were known. Dr Rutherforth's Effay on the Nature and Obligations of Virtue, publifhed in May 1744, foon engaged her thoughts; and notwithftanding the afthmatic diforder which had feized her many years before, and now left her fmall intervals of eafe, fhe applied herfelf to the confutation of that elaborate difcourfe, and finifhed it with a fpirit, elegance, and perfpicuity equal, if not fuperior, to all her former writings.

The lofs of her hufband in 1748, in the 71ft year of his age, was a fevere fhock to her; and fhe did not long furvive him, dying on the 11th of May 1749, in her 71ft year, after having long fupported a painful diforder with a refignation to the Divine will, which had been the governing principle of her whole life, and her fupport under the various trials of it.

Her works are collected into two large volumes 8vo, by Dr Birch; who has prefixed to them an account of her life and writings.

TROU JACOB, on the fouth fide of the ifland of St Domingo. From this to Cape Beate, or Cape a Foux, the fhore is rocky.—*Morse*.

TROU, Le, a fettlement in the northern part of the French divifion of the ifland of St Domingo. It is $5\frac{1}{2}$ leagues E. of Ouanaminthe, and 2 S. E. of Limonade. N. lat. 19 35, W. long. from Paris 74 22.—*ib.*

TROY, a poft-town of New-York, Ranffelaer county, 6 miles north of Albany, 3 S. of Lanfingburg city, and 271 from Philadelphia. The townfhip of Troy is bounded E. by Peterfburg, and was taken from Renffellaerwyck townfhip, and incorporated in 1791. In 1796, 550 of the inhabitants were electors. Seven years ago, the fcite of the flourifhing village of Troy was covered with flocks and herds, and the fpot on which a fchool, containing 160 fcholars, is now erected, was then probably a fheepfold. The fchool is under the direction of three fchoolmafters, and is a very promifing feminary.—*ib.*

Trumpet Marine.

TRUMPET Marine, or Marigny. This is a ftringed inftrument, invented in the 16th century by an Italian artift Marino or Marigni, and called a *trumpet*, becaufe it takes only the notes of the trumpet, with all its omiffions and imperfections, and can therefore execute only fuch melodies as are fitted for that inftrument. It is a very curious inftrument, though of fmall mufical powers, becaufe its mode of performance is totally unlike that of other ftringed inftruments; and it deferves our very particular attention, becaufe it lays open the mechanifm of mufical founds more than any thing we are acquainted with; and we fhall therefore make ufe of it in order to communicate to our readers a philofophical theory of mufic, which we have already treated in detail as a liberal or fcientific art.

The trumpet marine is commonly made in the form of a long triangular pyramid, ABCD, fig. A. on which a fingle ftring EFG is ftrained over a bridge F by means of the finger pin L. At the narrow end are feveral frets 1, 2, 3, 4, 5, &c. between E and K, which divide the length EF into aliquot parts. Thus E 1 is $\frac{1}{12}$ of EF, E 2 is $\frac{1}{11}$, and fo on. The bow is drawn lightly acrofs the cord at H, and the ftring is ftopped by preffing it with the finger immediately above the frets, but not fo hard as to make it touch the fret. When the open ftring is founded, it gives the fundamental note. If it be ftopped, in the way now defcribed, at $\frac{1}{3}$d of its length from E, it yields the 12th of the fundamental; if ftopped at $\frac{1}{4}$th, it gives the double octave; if at $\frac{1}{5}$th, it gives the 17th major, &c. In fhort, it always gives the note correfponding to the length of the part between the fret and the nut E. The founds refemble thofe of a pipe, and are indeed the fame with thofe known by the name *harmonics*, and now executed by every performer on inftruments of the viol or violin fpecies. But in order to increafe the noife, the bridge F is conftructed in a very particular manner. It does not reft on the found-board of the inftrument through its whole breadth, but only at the corner *a*, where it is firmly fixed. The other extremity is detached about $\frac{1}{100}$ of an inch from the found-board; and thus the bridge being made to tremble by the ftrong vibration of the thick cord, rattles on the found-board, or on a bit of ivory glued to it. The ufual way in which this motion is procured, is to have another ftring paffing under the middle of the bridge in fuch a manner that, by ftraining it tight, we raife the corner *b* from the found-board to the proper height. This contrivance increafes prodigioufly the noife of the inftrument, and gives it fomewhat of the fmart found of the trumpet, though very harfh and coarfe. But it merits the attention of every perfon who wifhes to know any thing of the philofophy of mufical founds, and we fhall therefore fay as much on the fubject as will conduce to this effect.

Plate XLV.

Galileo, as we have obferved in the article Temperament, *Suppl.* was the firft who difcovered the real connection between mathematics and mufic, by demonftrating that the times of the vibrations of elaftic cords of the fame matter and fize, and ftretched by equal weights, are proportional to the lengths of the ftrings. He

Trumpet Marine.

He inferred from this that the musical pitch of the sound produced by a stretched cord depended solely on the frequency of the vibrations. Moreover, not being able to discover any other circumstance in which those sounds physically resembled each other, and reflecting that all sounds are immediately produced by agitations of air acting on the ear, he concluded that each vibration of the cord produced a sonorous pulse in the air, and therefore that the pitch of *any* sound whatever depended on the frequency of the aerial pulses. In this way alone the sound of a string, of a bell, of an organ pipe, and the bellow of a bull, may have the same pitch. He could not, however, demonstrate this in any case but the one above mentioned. But he was encouraged to hope that mathematicians would be able to demonstrate it in all cases, by his having observed that the same proportions obtained in organ pipes as in strings stretched by equal weights. But it required a great progress in mechanical philosophy, from the state in which Galileo found it, before men could speculate and reason concerning the pulses of air, and discover any analogy between them and the vibrations of a string. This analogy, however, was discovered, and its demonstration completed, as we shall see by and by. In the mean time, Galileo's demonstration of the vibrations of elastic cords became the foundation of all musical philosophy. It must be thoroughly understood before we can explain the performance of the trumpet marine.

The demonstration of Galileo is remarkable for that beautiful simplicity and perspicuity which distinguish all the writings of that great mechanician, and it is the elementary proposition in all mechanical treatises of music. Few of them indeed contain any thing more; but it is extremely imperfect, and is just only on the supposition that all the matter of the string is collected at its middle point, and that the rest of it has elasticity without *inertia*. This did not suit the accurate knowledge of the last century, after Huyghens and Newton had given the world a taste of what might be done by prosecuting the Galilean mechanics. When a musical cord has its middle point drawn aside, and it is strained into the shape of two strait lines, if it be let go, it will be observed not to vibrate in this form. It may easily be seen in the extremity of its excursions, where it rests, before it return by its elasticity. The reason is this (see fig. B.) When the middle point C of the cord is drawn aside, and the cord has the form of two straight lines AC, CB, this point C, being pulled in the directions CA, CB, at once, is really accelerated in the direction CD, which bisects the angle ACB; and if it were then detached from the rest of the material cord, it would move in that direction. But any other point *f* between C and B has no accelerating force whatever acting on it. It is equally pulled in the directions *f* C and *f* B. The particle C therefore is obliged to drag along with it the inert matter of the rest of the cord; and when it has come to any intermediate situation *c*, the cord cannot have the form of two straight lines A *c*, *c* B, with the particle *f* situated in '*f*. This particle will be left somewhat behind, as in *φ*, and the cord will have a curved form A *c φ* B; and in this form it will vibrate, going to the other side, and assuming, not the rectilineal form ADB, but the curved form A *δ* B. That every particle of the curve A *e c* '*f* B is now accelerated toward the axis AB is evident, because every part is curved, and the whole is strained toward A and B, which tends to straighten every part of it. But in order that the whole may arrive at the axis in one moment, and constitute a straight line AB, it is evidently necessary that the accelerating force on every particle be as the distance of the particle from that point of the axis at which it arrives. It is well known to the mathematician that the accelerating force by which any particle is urged towards a rectilineal position, with respect to the adjoining particles, is proportional to the curvature. Our readers who are not familiar with such discussions, may see the truth of this fundamental proposition by considering the whole of A *c* B as only a particle or minute portion of a curve, magnified by a microscope. The force which strains the curve may be represented by *c* A or AE. Now it is well known (and is the foundation of Galileo's demonstration) that the straining force is to the force with which *c* is accelerated in the direction *c* E as A *c* to *c* D, or as AE to *c* D, or as AE to twice *c* E. Now *c* E is the measure of the curvature of A *c* B, being its deflection from a right line. Therefore when the straining force is the same all over the curve, the accelerating force, by which any portion of it tends to become straight, is proportional to the curvature of that portion. And if r be the radius of a circle passing through A, c, and B, and coinciding with this element of a curve, it is plain that $cD : cA = cA : r$, or that the radius of curvature is to the element cA as the extending force to the accelerating force; and $cD = \frac{cA^2}{r}$; and is inversely as r, or directly as the curvature.

Hence we see the nature of that curve which a musical chord must have, in order that all its parts may arrive at the axis at once. The curvature at *c* must be to the curvature at *f* as E *c* to *g f*. But this may not be enough. It is farther necessary that when *c* has got half way to E, the curvature in the different points of the new curve into which the cord has now arranged itself, be also, in every point, proportional to the distance from the axis. Now this *will* be the case if the extreme curve has been such. For, taking the cord in any other successive shape, the distance which each point has gone in the same moment must be proportional to the force which impelled it; therefore the remaining distances of all the points from the axis will have the same proportion as before. And the geometrical and evident consequence of this is, that the curvatures will also be in the same proportion.

Therefore a cord that is once arranged in this form will always preserve it, and will vibrate like a cycloidal pendulum, performing its oscillations in equal times, whether they be wide or narrow. Therefore since this perfect isochronism of vibrations is all that is wanted for preserving the same musical pitch or tone, this cord will always have the same note.

This proposition was the discovery of Dr Brooke Taylor, one of the ornaments of our country*, and is published in his celebrated work *Methodus Incrementorum*. The investigation, however, and the demonstration in that work, are so obscure and so tedious that few had patience to peruse them. It was more elegantly treated afterwards by the Bernoullis and others. The curve got the name of the *Taylorean curve;* and is considered by many eminent mathematicians as a trochoid, *viz.*

* See life, E

mpet rine.

viz. the curve deſcribed by a point in the nave or ſpoke of a wheel while the wheel rolls along a ſtraight line. But this is a miſtake, although it is allied to the trochoid in the ſame manner that the figure of ſines is allied to the cycloid. Its phyſical property intitles it to the name of the HARMONICAL CURVE. As this curve is not only the foundation of all our knowledge of the vibration of elaſtic cords, but alſo furniſhes an equation which will lead the mathematician through the whole labyrinth of aereal undulations, and be of uſe on many other occaſions; and as the firſt mathematicians have, through inattention, or through enmity to Dr Taylor, affected to conſider it as the trochoid already well known to themſelves—we ſhall give a ſhort account of its conſtruction and chief properties, ſimplified from the elegant deſcription given by Dr Smith in his Harmonics.

Let SDTV, QERP (fig. C.), be circles deſcribed round the centre C. Draw the diameters QCR, ECP, cutting each other at right angles. From any point G in the exterior circle draw the radius GC, cutting the interior circle in F, draw KHFI parallel to QCR, and make HI, HK, each equal to the arch EG. Let this be done for every point of the quadrantal arch EGR. The points I, K, are in the harmonic curve; that is, the curve AKDIB paſſing through the points K and I, determined by this conſtruction, has its curvature in every point K proportional to the diſtance KN from the baſe AB.

To demonſtrate this, draw FL perpendicular to the axis, and join EL. Take another point *g* in the outer circle indefinitely near to G. Draw *g c*, cutting the inner circle in *f*, and *f h* and *f l* perpendicular to DC, CT, and join E *l*. Then ſuppoſe two lines K*m*′, K*m*′ perpendicular to the curve in K and *k*. They muſt meet in *m*′, the centre of the equicurve circle. Draw KN*n*′ perpendicular to the baſe, and *m*′ *n*′ parallel to it, and join *k n*. Laſtly, draw XL *x* perpendicular to EL.

It is plain that *k* O, the difference of HK and *h k*, is equal to G *g*, the difference of GE and *g* E, and that KO is equal to F *r*, and L *l* to *r f*. Alſo, becauſe ELX is a right angle, $EX = \frac{EL^2}{EC}$.

We have $Fr : Ff = CL : CF, = CL : CD.$

$Ff : Gg = \quad CD : CE.$

Therefore $Fr : Gg$, or $KO : Ok = CL : CE$.

The triangles ECL and *k*OK are therefore ſimilar, as are alſo *k*OK and K *n m*, and conſequently ECL and K *n m*; and becauſe EC is parallel to K *n*, EL is parallel to K *m*. For the ſame reaſon *km* is parallel to E*l*, and the triangles E *l x* and *m* K *k* are ſimilar, and

$Lx : Kk = LE : Km,$

and $Lx : Kk = EC : Kn$. But farther,

$Lx : Ll = CE : CL$

$Ll : Ff = KN : CD$, being $= FL : FC$

$Ff : Gg = CD : CE$, being $= Ff : kO$

$Gg : Kk = CE : CL$, being $= KO : Kk$.

Therefore $Lx : Kk = KN \times CE : EL^2, = KN : EX.$

Therefore $KN : EX = LE : Km$, and $Km = \frac{EX \cdot LE}{KN}$,

and $KN : EX = CE : Kn$, and $Kn = \frac{EX \cdot CE}{KN}$.

In the very narrow vibrations of muſical cords, CD is exceedingly ſmall in compariſon with CE, ſo that EX·EL, or EX CE, may, without ſenſible error, be taken for CE^2, and then we obtain K*m* or K*n* (which hardly differ) $= \frac{CE^2}{KN}$, and therefore the curvature is proportional to KN. The ſmall deviation from this ratio would ſeem to ſhew that this conſtruction does not give the harmonic curve with accuracy. But it is not ſo. For it will be found that although the curvature is not as KN, it is ſtill proportional to the ſpace which any particle K muſt really deſcribe in order to arrive at the axis. Theſe paths are lines whoſe curvatures diminiſh as they approach to DC.

Trumpet Marine.

We ſee 1*ſt*, that the baſe ACB of the curve is equal to the ſemicircular arch QER.

2*d*, Alſo that the tangent KZ in any point K is perpendicular to EL.

3*d*, We learn that the curvature at A and B is nothing, for in theſe two points KN is nothing.

4*th*, The radius of curvature at D is preciſely $= \frac{CE^2}{CD}$.

Therefore as the ſtring approaches the axis, and CD diminiſhes, the curvature diminiſhes in the ſame proportion. The vibrations therefore are performed like thoſe of a pendulum in a cycloid, and are iſochronous, whether wide or narrow, and therefore the muſical pitch is conſtant.

This is not ſtrictly true, becauſe in the wide vibrations the extenſion or extending force is ſomewhat greater. Hence it is that a ſtring when violently twanged ſounds a little ſharper at the beginning. Dr Long made a harpſichord whoſe ſtrings were ſtretched by weights, by which this imperfection was removed.

It is proper to exhibit the curvature at D in terms of the length AB, and of the greateſt excurſion *c* D. Therefore let *c* be the circumference of a circle whoſe diameter is 1. Let AB the length of the cord be = L, and let CD the ½ breadth of the vibration be B.

We had a little ago $Dm = \frac{CE^2}{CD}$, but $c : 1 = AB : CE$, and $CE = \frac{AB}{c}$, and $cE^2 = \frac{ABc}{c^2}$. Therefore $Dm = \frac{AB^2}{c^2 \times CD}, = \frac{L^2}{9{,}87 CD}$ nearly.

We can now tell the number of vibrations made in a ſecond by a ſtring. This we obtain by comparing its motion, when impelled by the accelerating force which acts on it, with its motion when acted on by its weight only. Therefore let L be the length of a ſtring, and W its weight, and let E be the ſtraining weight, or extending force. Let *f* be the force which accelerates the particle D *d* of the cord, and *w* the weight of that particle, while W is the weight of the whole cord. Let *z* be the ſpace which the particle D *d* would deſcribe during the time of one vibration by the uniform action of the force *f*, and let S be the ſpace which it would deſcribe in the ſame time by its weight *w* alone. Then (DYNAMICS, *Suppl.* n° 103. cor. 6.) the time in which *f* would impel the particle D *d* along ½ DC, is to the time of one vibration as $1 : c$. And ½ DC is to *z* as the ſquare of the time of deſcribing ½ DC, is to the ſquare of the time of deſcribing *z*; that is, $1 : c^2 = \frac{1}{2} DC : 2z$, and $c^2 . DC = 2z$.

Now, by the property of the harmonic curve,

$AB : Dm = 2z : AB$

But

Trumpet Marine.

$$\text{But } Dm : Dd = E : f$$
$$\text{And } Dd : AB = w : W$$
$$\text{Therefore } 2z \cdot E \cdot w = AB \cdot f \cdot W$$
$$\text{And } f : w = 2z \times E : AB \times W$$
$$\text{But } w : f = 2S : 2z$$
$$\text{Therefore } 2S \times E = AB \times W$$
$$\text{And } 2E : W = AB : S.$$

That is, a mufical cord, extended by a force E, performs one vibration DCV in the time that a heavy body defcribes a fpace S, which is to the length of the cord as its weight is to twice the extending force.

Now let g be the fpace through which a heavy body falls in one fecond, and let the time of a vibration (eftimated in parts of a fecond) be T. We have

$$AB : S = 2E : W$$
$$S : g = T^2 : 1^2$$
$$\text{Therefore } AB : g = 2E \cdot T^2 : W$$
$$\text{And } AB \times W = T^2 \times 2E \times g$$
$$\text{Therefore } T^2 = \frac{AB \times W}{2g.E}, \text{ and } T = \sqrt{\frac{AB \times W.}{2g.E}}$$

Let n be the number of vibrations made in a fecond.

$$n = \frac{1}{T}, = \sqrt{\frac{2g.E}{AB.W}} = \sqrt{\frac{2gE}{LW}}.$$

If the length of the cord be meafured in feet, $2g$ is very nearly 32. If in inches, $2g$ is 386, more nearly. Therefore $n = \sqrt{\frac{32\,E}{L.W}}$ or $\sqrt{\frac{386\,E}{L.W}}$. This may eafily be compared with obfervation. Dr Smith hung a weight of 7 pounds, or 49,000 grains, on a brafs wire fufpended from a finger pin, and fhortened it till it was in perfect unifon with the double octave below the open ftring D of a violin. In this ftate the wire was 35,55 inches long, and it weighed 31 grains.

Now $\sqrt{\frac{384 \times 49000}{35{,}55 \times 31}} = 130{,}7 = n$. This wire, therefore, ought to make 130,7 vibrations in a fecond. Dr Smith proceeded to afcertain the number of aereal pulfes made by this found, availing himfelf of the theory of the beats of tempered confonances invented by himfelf. On his fine chamber organ he tuned upwards the perfect fifths DA, A e, $e\,b$, and then tuned downward the perfect 6th $e\,d$. Thus he obtained an octave to D, which was too fharp by a comma, and he found that it beat 65 times in 20 feconds. Therefore the number of vibrations was $\frac{65}{20}$ 81, or 263,25. Thefe were complete pulfes or motions from D to V and back again, and therefore contained 526½ fuch vibrations as we have now been confidering. The double octave below fhould make ¼th of this, or 131,6, which is not a complete vibration more than the above theory requires: more accurate coincidence is needlefs.

This theory is therefore very completely eftablifhed, and it may be confidered as one of the fineft mechanical problems which has been folved in the 18th century. We mention it with the greater minutenefs, becaufe the merit of Dr Taylor is not fufficiently attended to. Mr Rameau, and the other great theorifts in mufic, make no mention of him; and fuch as have occafion to fpeak of the abfolute number of vibrations made by any mufical note, always quote Mr Sauveur of the French academy. This gentleman has written fome very excellent differtations on the theory of mufic, and Sir Ifaac Newton in his *Principia* often quotes his authority. He has given the actual determination of the number of vibrations of the note C, obtained in a manner fimilar to that practifed by Dr Smith on his chamber organ, and which agrees extremely well with that meafure. But Mr Sauveur has alfo given a mechanical inveftigation of the problem, which gives the fame number of vibrations that he obferved. We prefume that Rameau and others took the demonftration for good: and thus Mr Sauveur paffes on the continent for the difcoverer of this theorem. But it was not publifhed till 1716, though read in 1713; whereas Dr Taylor's demonftration was read to the Royal Society in May 1714. But this demonftration of Mr Sauveur is a mere paralogifm, where errors compenfate errors; and the affumption on which he proceeds is quite gratuitous, and has nothing to do with the fubject. Yet John Bernoulli, from enmity to Taylor and the Englifh mathematicians, takes not the leaft notice of this fophifticated demonftration, accommodated to the experiment, and fo devoid of any pretenfions to argument that this fevere critic could not but fee its falfity.

Sauveur was one of the firft who obferved diftinctly that remarkable fact which Mr Rameau made the foundation of his mufical theory, *viz.* that a full mufical note is accompanied by its octave, its twelfth, and its feventeenth major. It had been cafually obferved before, by Merfennus, by Perrault, and others; but Sauveur tells diftinctly how to make the obfervation, and affirms it to be true in all deep notes. Rameau afferts it to be univerfally and neceffarily true in all notes, and the foundation of all mufical pleafure.

It had been difcovered before this time, that not only a full note caufed its unifon to refound, but alfo that a 12th, being founded near any open ftring, the ftring *refounded* to this 12th. It does the fame to a 15th, a 17th major, a 22d, &c.

Dr Wallis added a very curious circumftance to this obfervation. Two of his pupils, Mr Noble and Mr Pigot, in 1673, amufing themfelves with thefe refonances, obferved, that if a fmall bit of paper be laid on the ftring of a violin which is made to refound to its unifon, the paper is thrown off: a proof that the ftring refounded by really vibrating, and that it is thrown into thefe vibrations by the pulfes of the air produced by the other ftring. In like manner the paper is thrown off when the ftring refounds to its octave. But the young gentlemen obferved, that when the paper was laid on the middle point of the ftring, it remained without agitation, although the ftring ftill refounded. They found the fame thing when they made the ftring refound to its 12th: papers laid on the two points of divifion lay ftill, but were thrown off when laid on any other place. In fhort, they found it a general rule, that papers laid on any points of divifion correfponding to the note which was refounded, were not agitated.

Dr Wallis (the greateft theorift in mufic of the 17th century) juftly concluded that thefe points of the refounding ftring were at reft, and that the intermediate parts were vibrating, and producing the notes correfponding to their lengths.

From this Mr Sauveur, with great propriety, deduced the theory of the performance of the trumpet marine, the vielle, the clavichord, and fome other inftruments.

When

mpet arine.

When the ſtring of the trumpet marine is gently ſtopped at $\frac{1}{2}$, and the bow drawn lightly acroſs it at H (fig. A), the full vibration at the finger is ſtopped; but the ſtring is thrown into vibrations of ſome kind, which will either be deſtroyed or may go on. It is of importance to ſee what circumſtance will permit their continuance.

Suppoſe an elaſtic cord put into the ſituation ABCDE, (fig. D), ſuch that AB, BC, CD, DE, are all equal, and that BCD is a ſtraight line. Let the point C be made faſt, and the two points B and D be let go at once. It is evident that the two parts will immediately vibrate in two harmonical curves A*b*C and CDE, which will change to ABC and C*d*E, and ſo on alternately. It is alſo evident that if a line FCG be drawn touching the curve ABC, it will alſo touch the curve CDE; and the line which touches the curve A*b*C in C, will alſo touch the curve C*d*E. In every inſtant the two halves of the cord will be curves which have a common tangent in the point C. The undoubted conſequence of this is, that the point C will not be affected by theſe vibrations, and its fixure may be taken away. The cord will continue to vibrate, and will give the ſound of the octave to its fundamental note.

The condition, then, which muſt be implemented, in order that a ſtring may reſound to its octave, or take the ſound of its octave, is ſimply this, that its two parts may vibrate equally in oppoſite directions. This is evidently poſſible; and when the bow is drawn acroſs the ſtring of the trumpet marine at H, and irregular vibrations are produced in the whole ſtring, thoſe which happen to be in one direction on both ſides of the middle point, where it is gently ſtopped by the finger, will deſtroy each other, and the conſpiring ones will be inſtantly produced, and then every ſucceeding action of the bow will increaſe them.

The ſame thing muſt happen if a ſtring is gently ſtopped at one-third of its length; for there will be the ſame equilibrium of forces at the two points of diviſion, ſo that the fixures of theſe points may be removed, and the ſtring will vibrate in three parts, ſounding the 12th of the fundamental.

We may obſerve, by the way, that if the bow be drawn acroſs the ſtring at one of the points of diviſion, correſponding to the ſtopping at the other end of the ſtring, it will hardly give any diſtinct note. It rattles, and is intolerably harſh. The reaſon is plain: The bow takes ſome hold of the point C, and drags it along with it. The cord on each ſide of C is left behind, and therefore the two curves cannot have a common tangent at C. The vibrations into which it is thus jogged by the bow deſtroy each other.

We now ſee why the trumpet marine will not ſound every note. It will ſound none but ſuch as correſpond to a diviſion of the ſtring into a number of equal parts, and its note will be in uniſon with a ſtring equal to one of thoſe parts. Therefore it will *firſt* of all ſound the fundamental, by its whole length;

2. Its octave, correſponding to - $\frac{1}{2}$ its length
3. The 12th, - - - $\frac{1}{3}$
4. The 15th, or double octave, - $\frac{1}{4}$
5. The 17th, - - - $\frac{1}{5}$
6. The 19th, - - - $\frac{1}{6}$
7. The 21ſt, which is not in the diatonic ſcale of our muſic, - $\frac{1}{7}$
8. The triple octave or 22d, $\frac{1}{8}$ its length
9. The 23d, or 2d in the ſcale of the triple octave, . - - $\frac{1}{9}$
10. The 24th or 3d in this ſcale, $\frac{1}{10}$
11. The 25th, a falſe 4th of this ſcale, $\frac{1}{11}$
12. The 26th, a perfect 5th of this ſcale, $\frac{1}{12}$
13. The 27th, a falſe 6th of ditto, $\frac{1}{13} = \frac{3}{39}$ or $\frac{4}{52}$
14. The 28th, a falſe 7th minor, - $\frac{1}{14}$
15. The 28th, a perfect 7th major, $\frac{1}{15}$
16. The quadruple octave, - $\frac{1}{16}$

Muſical Trumpet

Thus we ſee that this inſtrument will not execute all muſic, and indeed will not complete any octave, becauſe it will neither give a perfect 4th nor 6th. We ſhall preſently ſee that theſe are the very defects of the trumpet.

This ſingular ſtringed inſtrument has been deſcribed in this detail, chiefly with the view of preparing us for underſtanding the real trumpet. The Vielle, Savoyarde, or Hurdygurdy, performs in the ſame manner. While the wheel rubs one part of the ſtring like a bow, the keys gently preſs the ſtrings, in points of aliquot diviſion, and produce the harmonic notes.

It is to prevent ſuch notes that the part of harpſichord wires, lying between the bridge and the pins, are wrapped round with liſt. Theſe notes would frequently diſturb the muſic.

Laſtly on this head, the Æolian harp derives its vaſt variety of fine ſounds from this mode of vibration. Seldom do the cords perform their fundamental or ſimple vibrations. They are generally ſounding ſome of the harmonies of their fundamentals, and give us all this variety from ſtrings tuned in uniſon.

Trumpet, Muſical, is a wind inſtrument which ſounds by preſſing the cloſed lips to the ſmall end, and forcing the wind through a very narrow aperture between the lips. This is one of the moſt ancient of muſical inſtruments, and has appeared in all nations in a vaſt variety of forms. The conch of the ſavage, the horn of the cowherd and of the poſtman, the bugle horn, the lituus and tuba of the Romans, the military trumpet, and the trombone, the *cor de chaſſe* or French horn—are all inſtruments winded in the ſame manner, producing their variety of tones by varying the manner and force of blowing. The ſerpent is another inſtrument of the ſame kind, but producing part of its notes by means of holes in the ſides.

Although the trumpet is the ſimpleſt of all muſical inſtruments, being nothing but a long tube, narrow at one end and wide at the other, it is the moſt difficult to be explained. To underſtand how ſonorous and regulated undulations can be excited in a tube without any previous vibration of reeds to form the waves at the entry, or of holes to vary the notes, requires a very nice attention to the mechaniſm of aereal undulations, and we are by no means certain that we have as yet hit on the true explanation. We are certain, however, that theſe aereal undulations do not differ from thoſe produced by the vibration of ſtrings; for they make ſtrings reſound in the ſame manner as vibrating cords do. Galileo, however, did not know this argument for his aſſertion that the muſical pitch of a pipe, like that of a cord, depended on the frequency alone of the aereal undulations; but he thought it highly probable, from his obſervations on the ſtructure of organs, that the notes of pipes were related to their lengths in the ſame manner as thoſe of wires, and he expreſsly makes this remark.

remark. Newton having difcovered that found moved at the rate of about 960 feet per fecond, obferved that, according to the experiments of Mr Sauveur, the length of an open pipe is half the length of an aereal pulfe. This he could eafily afcertain by dividing the fpace defcribed by found in a fecond by the number of pulfes.

Daniel Bernoulli, the celebrated promoter of the Newtonian mechanics, difcovered, or at leaft was the firft who attentively marked, fome other circumftances of refemblance between the undulations of the air in pipes and the vibrations of wires. As a wire can be made, not only to vibrate in its full length, founding its fundamental note, but can alfo be made to fubdivide itfelf, and vibrate like a portion of the whole, with points of reft between the vibrating portions, when it gives one of its harmonic notes; fo a pipe cannot only have fuch undulations of air going on within it as are competent to the production of its fundamental note, but alfo thofe which produce one of its harmonic notes. Every one knows that when we force a flute by blowing too ftrongly, it quits its proper note, and gives the octave above. Forcing ftill more, produces the 12th. Then we can produce the double octave or 15th, and the 17th major, &c. In fhort, by attending to feveral circumftances in the manner of blowing, all the notes may be produced from one very long pipe that we produce from the trumpet marine, and in precifely the fame order, and with the fame omiffions and imperfections. This alone is almoft equivalent to a proof that the mechanifm of the undulations of air in a pipe are analogous to that of the vibrations of an elaftic cord. Having with fo great fuccefs inveftigated the mechanifm of the partial vibrations of wires, and alfo another kind of vibrations which we fhall mention afterwards, incomparably more curious and more important in the philofophy of mufical founds, Mr Bernoulli undertook the inveftigation of thofe more myfterious motions of air which are produced in pipes; and in a very ingenious differtation, publifhed in the Memoirs of the Academy of Paris for 1762, &c. he gives a theory of them, which tallies in a wonderful manner with the chief phenomena which we obferve in the wind inftruments of the flute and trumpet kind. We are not, however, fo well fatisfied with the truth of his *affumptions* refpecting the ftate of the air, and the precife form of the undulations which he affigns to it; but we fee that, notwithftanding a probability of his being miftaken in thefe circumftances (it is with great deference that we prefume to fuppofe him miftaken), the chief propofitions are ftill true; and that the changes from note to note muft be produced in the order, though perhaps not in the precife manner, affigned by him.

It is by no means eafy to conceive, with clearnefs, the way in which mufical undulations are excited in the various kinds of trumpets. Many who have reputation as mechanicians, fuppofe that it is by means of vibrations of the lips, in the fame manner as in the hautboy, clarionette, and reed pipes of the organ, where the air, fay they, is put in motion by the trembling reed. But this explanation is wrong in all its parts; even in the reed-pipes of an organ, the air is *not* put in motion by the reeds. They are indeed the *occafions* of its mufical undulation, but they do not *immediately impel* it into thofe waves. This method (and indeed all methods but the vibrations of wires, bells, &c.) of producing found is little underftood, though it is highly worthy of notice, being the origin of animal voice, and becaufe a knowledge of it would enable the artifts to entertain us with founds hitherto unknown, and thus add confiderably to this gift of our Bountiful Father, who has fhewn in the ftructure of the larynx of the human fpecies, that he intended that we fhould enjoy the pleafures of mufic as a *laborum dulce lenimen*. He has there placed a micrometer apparatus, by which, *after* the other mufcles have done their part in bringing the glottis nearly to the tenfion which the intended note requires, we can eafily, and inftantly, adjuft it with the utmoft nicety.

We truft, therefore, that our readers will indulge us while we give a very curfory view of the manner in which the tremulous motion of the glottis, or of a reed in an organ pipe, produces the fonorous undulations with a conftant or uniform frequency, fo as to yield a mufical note.

If we blow through a fmall pipe or quill, we produce only a whizzing or hiffing noife. If, in blowing, we fhut the entry with our tongue, we hear fomething like a folid blow or tap, and it is accompanied with fome faint perception of a mufical pitch, juft as when we tap with the finger on one of the holes of a flute when all the reft are fhut. We are then fenfible of a difference of pitch according to the length of the pipe; a longer pipe or quill giving a graver found. Here, then, is like the beginning of a fonorous undulation. Let us confider the ftate of the air in the pipe: It was filled by a column of air, which was moving forward, and would have been fucceeded by other air in the fame ftate. This air was therefore nearly in its ftate of natural denfity. When the entry is fuddenly ftopped by the tongue, the included air already in motion, continues its motion. This it cannot do without growing rarer, and then it is no longer a balance for the preffure of the atmofphere. It is therefore retarded in its motion, totally ftopped (being in a rarefied ftate), and is then preffed back again. It comes back with an accelerated motion, and recovers its natural denfity, while the ftate of rarefaction goes forward through the open air like any other aereal pulfe. Its motions are fomewhat, but not altogether, like that of a fpiral wire, which has been in like manner moving uniformly along the pipe, and has been ftopped by fomething catching hold of its hindermoft extremity. This fpring, when thus catched behind, ftretches itfelf a little, then contracts *beyond* its natural ftate, and than expands again, quivering feveral times. It can be demonftrated that the column of air will make but one quiver. Suppofe this accomplifhed in the hundredth part of a fecond, and that at that inftant the tongue is removed for the hundredth part of a fecond, and again applied to the entry of the pipe. It is plain that this will produce fuch another pulfe, which will join to the former one, and force it out into the air, and the two pulfes together will be like two pulfes produced by the vibration of a cord. If, inftead of the tongue we fuppofe the flat plate of an organ-reed to be thus alternately applied to the hole and removed, at the exact moments that the renewals of air are wanted, it is plain that we fhall have *fonorous* undulations of *uniform* frequency, and therefore a mufical note. This is the way in which reeds produce their effect, not by *impelling* the air into alternate ftates

ftates of motion to and fro, and alternate ftrata of rarefied and condenfed air, but by giving them time to acquire this ftate by the combination of the air's elafticity with its progreffive motion.

The adjuftment of the fucceeding puff of air to the pulfe which precedes it, fo that they may make one fmooth and regular pulfe, is more exact than we have yet remarked; for the ftoppage of the hole not only *occafions* a rarefaction *before it*, but by checking the air which was juft going to enter, makes a condenfation *behind the door* (fo to fpeak); fo that, when the paffage is again opened, the two parcels of air are fitted for fupporting each other, and forming one pulfe.

Suppofe, in the next place, that the reed, inftead of completely fhutting the hole each time, only half fhuts it. The fame thing muft ftill happen, although not in fo remarkable a degree. When the paffage is contracted, the fupply is diminifhed, and the air now in the pipe muft rarefy, by advancing with its former velocity. It muft therefore retard; by retarding regain its former denfity; and the air not yet got into the pipe, muft condenfe, &c. And if the paffage be again opened or enlarged in the proper time, we fhall have a complete pulfe of condenfed and rarefied air; and this muft be accompanied by the beginning of a mufical note, which may be continued like the former.

This will be a fofter or more mellow note than the other; for the condenfed and rarefied air will not be fo fuddenly changed in their denfities. The difference will be like the difference of the notes produced by drawing a quill along the teeth of a comb, and that produced by the equally rapid vibrations of a wire. For let it be remarked here, that mufical notes are by no means confined, as theorifts commonly fuppofe, to the regular cycloidal agitations of air, fuch as are produced by the vibrations of an elaftic cord; but that any crack, fnap, or noife whatever, when repeated with fufficient frequency, becomes *ipfo facto* a mufical found, of which we can tell the pitch or note. What can be lefs mufical than the folitary cracks of fnaps made by a ftiff door when very flowly opened? Do this brifkly, and the creak changes to a chirp, of which we can tell the note. The founds will be harfh or fmooth, according as the fnaps of which they are compofed are abrupt or gradual.

This diftinction of founds is moft fatisfactorily confirmed by experiment. If the tongue of the organ reed is quite flat, and if, in its vibrations, it apply itfelf to the whole margin of the hole at once, fo as completely to fhut it (as is the cafe in the oldfafhioned regal ftop of the organ), the note is clear, fmart, and harfh or hard: but if the lips of the reed are curved, or the tongue properly bent backward, fo that it applies itfelf to the edges of the hole *gradatim*, and never completely fhuts the paffage, the note may have any degree of mellow fweetnefs. This remark is worth the attention of the inftrument-makers or organ builders, and enables them to vary the VOICE of the organ at pleafure. We only mention it here as introductory to the explanation of the founds of the trumpet.

We truft that the reader now perceives how the air, proceeding along a pipe, may be put in the ftate of alternate ftrata of condenfed and rarefied air, the particles, in the mean time, proceeding along the pipe with a very moderate velocity; while the *ftate of undulation* is propagated at the rate of eleven or twelve hundred feet in a fecond; juft as we may fometimes fee a ftream of water gliding gently down a canal, while a wave runs along its furface with much greater rapidity.

It will greatly affift the imagination, if we compare thefe aëreal undulations with the undulations of water in an open canal. While the water is flowing fmoothly along, fuppofe a fluice to be thruft up from the bottom quite to the furface, or beyond it. This will immediately caufe a depreffion on the lower fide of the fluice, by the water's going along the canal, and a heaping up of the water on the other fide. By properly timing the motion of this fluice up and down, we can produce a feries of connected waves. If the fluice be not pufhed up to the furface but only one-half way, there will be the fame fucceffion of waves, but much fmoother, &c. &c.

It is in this ftate, though not by fuch means, that the air is contained in a founding trumpet. It is not brought into this ftate by any tremor of the lips. The trumpeter fometimes feels fuch a tremor; but whenever he feels it, he can no longer found his note. His lips are painfully tickled, and he muft change his manner of winding.

When blowing with great delicacy and care, the deepeft notes of a French horn, or trombone, we fometimes can feel the undulations of the air in the pipe diftinctly fluttering and beating againft the lips; and it is difficult to hinder the lips from being affected by it; but we feel plainly that it is not the lips which are fluttering, but the air before them. We feel a curious inftance of this when we attempt to whiftle in concert. If our accompanier intonates with a certain degree of incorrectnefs, we feel fomething at our own lips which makes it impoffible to utter the intended note. This happens very frequently to the perfon who is whiftling the upper note of a greater third. In like manner, the undulations in a pipe react on the reed, and check its vibrations. For if the dimenfions of a pipe are fuch that the undulations formed by the reed cannot be kept up in the pipe, or do not fuit the length of the pipe, the reed will either not play at all, or will vibrate only in ftarts. This is finely illuftrated by a beautiful and inftructive experiment. Take a fmall reed of the *vox humana* ftop of an organ, and fet it in a glafs foot, adapted to the windbox of the organ. Inftead of the common pipe above it, fix on it the fliding tube of a fmall telefcope. When all the joints are thruft down, touch the key, and look attentively to the play of the reed. While it is founding, draw out the joints, making the pipe continually longer. We fhall obferve the reed thrown into ftrange fits of quivering, and fometimes quite motionlefs, and then thrown into wide fonorous vibrations, according as the *maintainable* pulfe is commenfurate or not with the vibrations of the reed. This plainly fhews that the air is not impelled into its undulations by the reed, but that the reed accommodates itfelf to the undulations in the pipe.

We acknowledge that we cannot explain with diftinctnefs in what manner the air in a trumpet is firft put into mufical undulations. We fee that it is only in very long and flender tubes that this can be done. In fhort tubes, of confiderable diameter, like the cowherd's horn, we obtain only one or two very indiftinct notes, of which it is difficult to name the pitch; and this requires great force of blaft; whereas, to bring out

out the deep notes of the French horn, a very gentle and well regulated blaft is neceffary. The form of the lips, combined with the force of the blaft, form all the notes. But this is in a way that cannot be taught by any defcription. The performer learns it by habit, and *feels* that the inftrument leaps into its note without him, when he gradually varies his blaft, and continues founding the fame note; although he, in the mean time, makes fome fmall change in his manner of blowing. This is owing to what Mr Bernoulli obferved. The tube is fuited only to fuch pulfes, and can only maintain fuch pulfes as correfpond to aliquot parts of its length; and when the embouchure is very nearly, but not accurately, fuited to a particular note, that note *forms itfelf* in the tube, and, reacting on the lips, brings them into the form which can maintain it with eafe. We have a proof of this when we attempt to found the note correfponding to one-feventh of the length. Not having a diftinct notion of this note, which makes no part of our fcale of melody, we cannot eafily prepare for it in the way that habit teaches us to prepare for the others: whereas, from what we fhall fee prefently, the notes *one-fixth* and *one-eighth* are both familiar to the mind, and eafily produced. When, therefore, we attempt to produce the note *one-feventh*, we flide, againft our will, into the *one-fixth* or *one eighth*.

Nor can we completely illuftrate the formation of mufical pulfes by waves in water. A canal is equally fufceptible of every height and length of progreffive waves; whereas we fee that a certain length of tube will maintain only certain determined pulfes of air.

We muft therefore content ourfelves for the prefent with having learned, by means of the reed pipes, how the air may exift progreffively in a tube, in an alternate ftate of condenfation and rarefaction; and we fhall now proceed to confider how this ftate of the air is related to the length of the tube. And here we can do no more than give an outline of Mr Bernoulli's beautiful theory of flutes and trumpets, but without a mathematical examination of the particular motions. We can, however, fhew, with fufficient evidence, how the different notes are produced from the fame tube. It requires, however, a very fteady attention from the reader to enable him to perceive how the different portions of this air act on each other. We truft that this will now be given.

The conditions which muft be implemented, in order to maintain a mufical pulfe, are two: 1. That the vibrations of the different plates of air be performed in equal times, otherwife they would all mix and confound each other. 2. That they move all together, all beginning and all ending at the fame inftant. It does not appear that any other ftate of vibration can exift and be maintained.

The column of air in a tube may be confidered as a material fpring (having weight and inertia). This fpring is compreffed and coiled up by the preffure of the atmofphere. But in this coiled ftate it can vibrate in its different parts, as a long fpiral wire may do, though preffed a little together at the ends. It is evident that the air within a pipe, fhut at both ends, may be placed in fuch a fituation, *in a variety of ways*, that it will vibrate in every part, in the fame manner as a chord of the fame length and weight, ftrained by a force equal to the preffure of the atmofphere. Thus, in the fhut pipe AB (fig. 1.), fuppofe a harmonic curve ACB, or a wire of the fame weight with the air, throwing itfelf into the form of this curve. The force which impels the point C to the axis is to that which impels the point *c* as CE to *ce*. Now, fuppofe the air in this pipe divided into parallel ftrata or plates, croffing the tube like diaphragms. In order that thefe may vibrate in the fame manner (not acrofs the tube, but in the direction of its axis), all that is neceffary for the moment is, that the excefs of the preffure of the ftratum *dd* above that of the ftratum *ff* may be to the excefs of the preffure of DD above that of FF as *ce* to CE. In this cafe, the ftratum *ce* will be accelerated in the direction *ef*, and the ftratum EE is accelerated in the fame direction, and in the due proportion. Now this may be done in an infinite variety of ways for a fingle moment. It depends, not on the abfolute denfity, but on the *variation* of denfity; becaufe the preffure by which a particle of air is urged in any direction arifes from the *difference* of the diftances of the adjoining particles on each fide of it. But in order to *continue* this vibration, or in order that it may obtain at once in the whole pipe, this variation of denfity muft continue, and be according to fome connected law. This circumftance greatly limits the ways in which the vibration may be kept up. Mr Bernoulli finds that the ifochronifm and fynchronifm can be maintained in the following manner, and in no other that he could think of:

Let AB (fig. 2.) be a cylindrical pipe, fhut at A, and open at B. Then, in whatever manner the found is produced in the pipe, the undulations of the contained air muft be performed as follows: Let *aa* be a plate of air. This plate will approach to, and recede from, the fhut end A, vibrating between the fituations *bb* and *cc*, the whole vibration being *bc*, and the plate will vibrate like a pendulum in a cycloid. The greater we fuppofe the excurfions *ab*, *ac*, the louder will the found be; but the duration of them all muft be the fame, to agree with the fact that the tone remains the fame. The motion will be accelerated in approaching to *aa* from either fide, and retarded in the recefs from it. Let us next confider a plate $\alpha\alpha$, more remote from A. It muft make fimilar vibrations from the fituation $\beta\beta$ to the fituation $\gamma\gamma$. But thefe vibrations muft be greater in proportion as the plate is farther from A. It cannot be conceived otherwife: For fuppofe the plate $\alpha\alpha$ to make the *fame* excurfions with *aa*, and that the reft do the fame. Then they will all retain the fame diftances from each other; and thus there will be no force whatever acting on any particles to make them vibrate. But if every particle make excurfions proportional to its diftance from A, the *variation* of denfity will, in any inftant, be the fame through the whole pipe, and each particle in the vibrating plate $\beta\beta$ will be accelerated or retarded in proportion to its diftance from A; while the accelerations and retardations over all will, in any inftant, be proportional to the diftance of each particle from its place of reft. All this will appear to the mathematician, who attentively confiders any momentary fituation of the particles. In this manner all the particles will fupport each other in their vibrations.

It follows from this defcription that the air in the tube is alternately rarefied and condenfed. But thefe changes are very different in different parts of the tube. They muft be greateft of all at A; becaufe, while all the

the plates approach to A, they concur in condenfing the air immediately adjoining to A; while the air in *a a* and *α α* is lefs condenfed by the action of the plates beyond it. The air at B is always of its natural denfity, being in equilibrio with the furrounding air. At B, therefore, there is a fmall parcel of air, of its natural denfity, which is alternately going in and out.

This account is confirmed by many facts. If the bottom of the pipe be fhut by a fine membrane, ftretched acrofs it like a drumhead, with a wire ftretched over it, either externally or internally, in the fame manner as the catgut is ftretched acrofs the bottom of a drum, it will be thrown into ftrong vibrations, making a very loud noife, by rattling againft the crofs wire. The fame thing happens if the membrane be pafted over a hole clofe to the bottom, leaving a fmall fpace round the edge of the hole without pafte, fo that the membrane may play out and in, and rattle on the margin of the hole. This alfo makes a prodigious noife. Now, if the membrane be pafted on a hole far from the bottom, the agitations will be much fainter; and when the hole is near the mouth of the pipe, there will be none.— When a pipe has its air agitated in this manner, it is giving the loweft note of which it is fufceptible.

Let us next confider a pipe open at both ends. Let CB (fig. 3.) be this pipe. It is plain that, if there be a partition A in the middle, we fhall have two pipes AB, AC, each of which may undulate in the manner now defcribed, if the undulations in each be in oppofite directions. It is evidently poffible, alfo, that thefe undulations may be the fame in point of ftrength in both, and that they may begin in the fame inftant. In this cafe, the air on each fide of the partition will be in the fame ftate, whether of condenfation or rarefaction, and the partition A itfelf will always be in equilibrio. It will perfectly refemble the point C of the mufical cord BFCGH (fig. 6.), which is in equilibrio between the vibrating forces of its two parts. In the pipe, the plates of air on each fide are either both approaching it, or both receding from it, and the partition is either equally fqueezed from both fides, or equally drawn outwards. Confequently this partition may be removed, and the parcels of air on each fide will, in any inftant, fupport each other. There feems no other way of conceiving thefe vibrations in open pipes which will admit of an explanation by mechanical laws. The vibrations of all the plates muft be obtained without any mutual hinderance, in order to produce the tone which we really hear; and therefore fuch vibrations are impreffed by Nature on each plate of air.

But if this explanation be juft, it is plain that this pipe CB muft give the fame note with the pipe AB (fig. 2.) of half the length, fhut at one end. But the found, being doubled, with perfect confonance, muft be clear, ftrong, and mellow. Now this is perfectly agreeable to obfervation; and this fact is an unequivocal confirmation of the juftnefs of the theory. If we take a flender pipe, about fix inches long and one half of an inch wide, fhut at one end, and found it by blowing acrofs its mouth, as we whiftle on the pipe of a key, or acrofs a hole that is clofe to the mouth, and formed with an edge like the found-hole of a German flute, we fhall get a very diftinct and clear tone from it. If we now take a pipe of double the length, open at both ends, and blow acrofs its mouth, we obtain the fame note, but more clear and ftrong. And the note produced by blowing acrofs the mouth is not changed by a hole made exactly in the middle, in refpect of its mufical pitch, although it is greatly hurt in point of clearnefs and ftrength. Alfo a membrane at this hole is ftrongly agitated. All this is in perfect conformity to this mechanifm.

Thus we have, in a great meafure, explained the effect of an open and a fhut pipe. The fhut pipe is always an octave, graver than an open pipe of the fame length; becaufe the open pipe is in unifon with the fhut pipe of half the length.

Let AC (fig. 4.) be a pipe fhut at both ends. We may confider it as compofed of two pipes AB, BC, ftopped at A and C, and open at B. Undulations may be performed in each half precifely as in the pipe AB of fig. 2.; and they will not, in the fmalleft degree obftruct each other, if we only fuppofe that the plates in each half are vibrating at once in the *fame* direction. The condenfation in AB will correfpond with the rarefaction in BC, and the middle parcel B will maintain its natural denfity, vibrating to, and again acrofs the middle; and two plates *a a*, *α α*, which are equally diftant from B, will make equal excurfions in the fame direction.

We may produce found in this pipe by making an opening at B. Its note will be found to be the fame with that of BC of fig. 2. or of AB of fig. 2.

In the next place, let a pipe, fhut at one end, be confidered as divided into any odd number of equal parts, and let them be taken in pairs, beginning at the ftopped end, fo that there may be an odd one left at the open end. It is plain that each of thefe pairs may be confidered as a pipe ftopped at both ends, as in fig. 4.

For the partitions will, of themfelves, be in equilibrio, and may be removed, and vibrations may be maintained in the whole, confiftent with the vibration of the odd part at the open end; and thefe vibrations will all fupport each other, and the plates of air which are at the point of divifion will remain at reft. Conceive the pipe AB of fig. 2. to be added to the pipe AC of fig. 4. the part A of the firft being joined to A of the other. Now, fuppofe the vibrations to be performed in both, in fuch a manner that the fimultaneous undulations on each fide of the junction may be in oppofite directions. It is plain that the partition will be in equilibrio, and may be removed; and the plate of air will perform the fame office, being alternately the middle plate of a condenfed and of a rarefied parcel of air. The two pipes CA, AB will together give the fame note that AB would have given alone, but louder.

In like manner may another pipe, equal to AC, be joined to the fhut end of this compound pipe, as in fig. 5. and the three will ftill give the fame note that AB would have done alone.

And in the fame manner may any number of pipes, each equal to AC, be added, and the whole will give ftill the fame note that AB would have given alone.

Hence it legitimately follows, that if the undulations can be once begun in this manner in a pipe, it may give either the found competent to it, as a fingle pipe AB (fig. 2.); or it may give the found competent to a pipe of $\frac{1}{3}$d, $\frac{1}{5}$th, $\frac{1}{7}$th, &c. of its length; the undulations in each part AB, BC, CD, maintaining themfelves in the

the manner already described. This seems the only way in which they can be preserved, both isochronous and synchronous.

It is known that the gravest tones of pipes are as the lengths of the pipes, or the frequency of the undulations are inversely as their lengths. (This will be *demonstrated* presently). Therefore these accessory tones should be as the odd numbers 3, 5, 7, &c. and the whole tones, including the fundamental, should form the progression of the odd numbers 1, 3, 5, 7, &c.

This is abundantly confirmed by experiment. Take a German flute, and stop all the finger holes. The flute, by gradually forcing the blast, will give the fundamental, the 12th, the 17th, the 21st, &c. (A).

Again, let AD (fig. 6.) represent the length of a pipe. Construct on AD an harmonic curve AEBFCGHD, in such a manner that HD may be $\frac{1}{2}$ AB, $= \frac{1}{2}$ BC, $= \frac{1}{2}$ CH. The small ordinates *m n* will express the total excursion of the plates of air at the points *m*, *n*, &c. and those ordinates which are above the axis will express excursions on one side of the place of rest, and the ordinates below will mark the excursions in the opposite directions, in the same manner as if this harmonic curve were really a vibrating cord. These excursions are nothing in the points A, B, C, H, and are greatest at the points E, F, G, D, where the little mass of air retains its natural density, and travels to and again, condensing the air at B, or rarefying it, according as the parcels E and F are approaching to or receding from each other. The points A, B, C, H, may be called Nodes, and the parts E, F, G, D, may be called Bights or Loops. This represents very well to the eye the motion of the plates of air. The density and velocity need not be minutely considered at present. It is enough that we see that when the density is increasing at A, by the approach of the parcel E, it is diminishing at B by the recess of E and F; and increasing at C, by the approach of F and G, and diminishing at H, by the recess of G. In the next vibration it will be diminishing at A and C, and increasing at B and H. And thus the alternate nodes will be in the same state, and the adjoining nodes in opposite states.

The reader must carefully distinguish this motion from the undulatory motion of a pulse, investigated by Newton, and described in the article Acoustics, *Encycl.* That undulation is going on at the same time, and is *a result* of what we are now considering, and the cause of our hearing this undulation. The undulation we are now considering is the original agitation, or rather it is the sounding body, as much as a vibrating string or bell is; for it is not the trumpet that we hear, but the air trembling in the trumpet. The trumpet is performing the office, not of the string, but of the pin and bridge on which the string is strained. This is an important remark in the philosophy of musical sounds.

There is yet another set of notes producible from a pipe besides those which follow in the order of frequency 1, 3, 5, 7, &c.

Suppose a pipe open at both ends, sounding by blowing across the end, and undulating, as already described, with a node in the middle A (fig. 3.) If we still express the fundamental note of the pipe AB of fig. 2. by 1, it is plain that the fundamental of an open pipe of the same length will have the frequency of its undulations expressed by 2; because an open pipe of twice the length of AB (fig 2.) will be 1, the two pipes AB (fig. 2.), and CB (fig. 3.), being in unison.

But this open pipe may be made to undulate in another manner; for we have seen that AB of fig. 2. joined to CA of fig. 4. may sound altogether when the partition A is removed, still giving the note of AB (fig. 2.) Let such another as AB (fig. 2.) be added to the end C, and let the partition be removed. The whole may still undulate, and still produce the same note; that is, a pipe open at both ends may sound a note which is the fundamental of a pipe like AB (fig. 2.), but only one-fourth of its length. The pipe CB of fig. 3. may thus be supposed to be divided into four equal parts, CE, EA, AF, FB, of which the extreme parts EC and FB contain undulations similar to those in AB (fig. 2.); and the two middle parts contain undulations like those in CA (fig. 4.) The partitions at E and F may be removed, because the undulations in EC and EA will support each other, if they are in opposite directions; and those in FB and FA may support each other in the same manner.

It must here be remarked, that in this state of undulation the direction of the agitations at the two extremities is the same; for in the middle piece EF the particles are moving one way, condensing the air at E, while they rarefy it at F. Therefore, while the middle parcel is moving from E towards F, the air at B must be moving towards F, and the air at C must be moving from E. In short, the air at the two extremities must, in every instant, be moving in the opposite direction to that of the air in the middle.

In like manner, if the pipe CB of fig. 3. be divided into six parts, the two extreme parts may undulate like AB of fig. 2. and the four inner parts may undulate like two pipes, such as CA of fig. 4. and the whole will give the sound which makes the fundamental of a pipe, of one-sixth of the length, or having the frequency 6.

We may remark here, that the simultaneous motion of

(A) A little reflection will teach us that these tones will not be perfectly in the scale. A certain proportion between the diameter and length of the pipe produces a certain tone. Making the pipe wider or smaller flattens or sharpens this tone a little, and also greatly changes its clearness. Organ builders, who have tried every proportion, have adopted what they found best. This requires the diameter to be about $\frac{1}{11}$th or $\frac{1}{11}$th of the length. Therefore, when we cause the same pipe to sound different notes, we neglect this proportion; and the notes are false, and even very coarse, when we produce one corresponding to a very small portion of the pipe. For a similar reason, Mr Lambert found that, in order to make his pitch-pipe sound the octave to any of its notes, it was not sufficient to shorten its capacity one-half by pushing down the piston; he found that the part remaining must be less than the part taken off by a fixed quantity $1\frac{5}{11}$ inches. Or, the length which gave any note being x, the length for its octave must be $\frac{x - 1\frac{5}{11}}{2}$.

Musical Trumpet.

of the air at the extremities is in opposite directions, whereas in the last case it was in the same direction. This is easily seen; for as the partition which is between the two middle pieces must always be in equilibrio, the air must be coming in or going out at the extremities together. This circumstance must give some sensible difference of character to the sounds 4 and 6. In the one, the agitations at each end of the tube are in the same direction, and in the other they are in the opposite. Both produce pulses of sound which are conveyed to the ear. Thus we see that the air in a pipe open at both ends may undulate in two ways. It may undulate with a node in the middle, giving the note of AB (fig. 2.), or of its 3d, 5th, 7th, &c. part; and it may undulate with a loop or bight in the middle, sounding like $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{6}$, &c. of AB, fig. 2.

In like manner may this pipe produce sounds whose frequency are expressed by 8, 10, &c. and proceed as the even numbers.

This state of agitation may be represented in the same way that we represented the sounds 1, 3, 5, &c. by constructing on AM (fig. 7,) an harmonic curve, with any number of nodes and loops. Divide the parts AF, FD, DE, EM, equally in C, O, P, B. CB will correspond to the pipe, and the ordinates to the curve GFHDLEN will express the excursions of the plates of air.

If the pipe gives its fundamental note, its length must be represented by CO, and the undulations in it will resemble the vibrations of part CO of a cord, whose length AD is equal to 2CO, and which has a node in F.

If the pipe is sounding its octave, it will be represented by CP, and its undulations will resemble the vibrations of a cord CP, whose length AE is $\frac{3}{2}$ of CP, having nodes at F and D, &c. &c.

We can now see the possibility of such undulations existing in a pipe as will be permanent, and produce all the variety of notes by a mere change in the manner of blowing, and why these notes are in the order of the natural numbers, precisely as we observe to happen in winding the trumpet or French horn. We have, 1*st*, the fundamental expressed by 1; then the octave 2: then the 12th, 3; the double octave 4; then the third major of that octave 5, or 17th of the fundamental; then the octave of the 12th, or the 5th of this double octave = 6. We then jump to the triple octave 8, without producing the intermediate sound corresponding to $\frac{1}{7}$th of the pipe. With much attention we can hit it; and it is a fact that a person void of musical ear stumbles on it as easily as on any other. But the musician, finding this sound begin with hum, and his ear being grated with it, perhaps thinks that he is mistaking his embouchure, and he slides into the octave. After the triple octave, we easily hit the sounds corresponding to $\frac{1}{9}$ and $\frac{1}{10}$, which are the 2d and 3d of this octave. The next note $\frac{1}{11}$ is sharper than a just 4th. We easily produce the note 12, which is a just 5th; 13 is a false 6th; 14 is a sound of no use in our music, but easily hit; 15 and 16 give the exact 7th and 8th of this octave.

Thus, as we ascend, we introduce more notes into every octave, till at last we can nearly complete a very high octave; but in order to do this with success, and tolerable readiness, we must take an instrument of a very low pitch, that we may be able nearly to fill up the steps of the octave in which our melody lies. Few players can make the French horn or trombone sound its real fundamental, and the octave is generally mistaken for it. The proof of this is, that most players can give the 5th of the lowest note that they are able to produce; whereas the 5th of the real fundamental cannot be uttered. Therefore that lowest note is not the fundamental, but the octave to the fundamental.

Few performers can sound even this second octave on a short instrument, such as the ordinary military trumpet; and what they imagine to be the fundamental sound of this instrument is the double octave above it. This appears very strange; and it may be asked, how we know what is really the fundamental note of a trumpet? The answer to this is to be obtained only by demonstrating, on mechanical principles, what is the frequency of undulation corresponding to a given length of pipe. This is a proposition equally fundamental with its corresponding one in the theory of musical cords; but we have reserved it till now, because many readers would stop short at such an investigation, who are able to understand completely what we have now delivered concerning the music of the trumpet.

Suppose therefore a pipe shut at both ends, and that the whole weight of the contained air is concentrated in its middle point, the rest retaining its elasticity without inertia: or (which is a more accurate conception), let the middle point be conceived as extending its elasticity to the two extremities of the pipe, being repelled from each by a force inversely as the distance. Let the length of this pipe be L. This may also express the weight of the middle plate of air, which will always be proportional to the length of the pipe, because all is supposed to be concentrated there. Let E be the elasticity of the air. This must be measured by the pressure of the atmosphere, or by the weight of the column of mercury in the barometer. Perhaps the rationale of this will be better conceived by some readers by considering E as the height of a homogeneous atmosphere. Then it is plain that E is to L as the weight of this atmospheric column to the weight of the column of the same air which fills the pipe whose length is L. Then it is also plain that E is to L as the external pressure; and consequently, as the elasticity which supports that pressure is to the weight or inertia of the matter to be moved. Let this middle plate or diaphragm be withdrawn from its place of rest to the very small distance a. The elasticity or repulsion will be augmented on one side and diminished on the other; and the difference between them is the only force which impels the diaphragm toward the middle point, and causes it to vibrate, or produces the undulation. It is plain that the repulsion on one side is $\frac{\frac{1}{2}L}{\frac{1}{2}L - a} \times E$, or $\frac{L}{L - 2a}E$ $\left(\text{for } \frac{1}{2}L - a : \frac{1}{2}L = E : \frac{\frac{1}{2}LE}{\frac{1}{2}L - a}\right)$, and the repulsion on the other side is $\frac{\frac{1}{2}L}{\frac{1}{2}L + a} \times E$, or $\frac{L}{L + 2a}E$. The difference of these repulsions is $E \times L \times \frac{4a}{L^2 - 4^2}$. But as we suppose a exceedingly small in comparison with L, L, this difference, or the accelerating force, may safely be expressed by $E\frac{4a}{L}$, or $4a\frac{E}{L}$.

Hence we deduce, in the first place, that the undulations will be isochronous, whether wide or narrow; because the accelerating force is always proportional to the distance a from the middle point.

Now, let a pendulum, whose quantity of matter is L, and length a, be supposed to vibrate in a cycloid by the force $\frac{4a}{L}E$, or $\frac{4E}{L}a$. It must perform its vibrations in the same time with the plate of air; because the moving force, the matter to be moved, and the space along which they are to be similarly impelled, are the same in both cases. Let another pendulum, having the same quantity of matter L, vibrate by its weight L alone. In order that these two pendulums may vibrate in equal times, their lengths must be as the accelerating forces. Therefore we must have $\frac{4E}{L}a : L = a : \frac{aL^2}{4Ea}, = \frac{L^2}{4E}$, which is therefore the length of the synchronous pendulum.

Now, a cord without weight and inertia, but loaded with the weight L at its middle point, and strained by a weight E, and drawn from the axis to the distance a, is precisely similar in its motion to the diaphragm we are now considering, and must make its oscillations in the same time.

This is applicable to any number of plates of air, by substituting in the cord a loaded point for each of the plates; for when the case is thus changed, both in the pipe and the cord, the space to be passed over by the plate of air bears the same proportion to a, which is passed over by the whole air concentrated in the middle point, which the space to be passed over by the corresponding loaded point of the cord bears to that passed over by the whole matter of the cord concentrated in the middle point; and the same equality of ratios obtains in the accelerating forces of the plate of air and the corresponding loaded point of the cord. Suppose, then, a pipe divided into 2, 3, 4, &c. equal parts, by 1, 2, 3, diaphragms, each of which contains the air of the intervening portions of the pipe, the whole weight L being equally divided among them. If there be but one diaphragm, its weight must be L; if two, the weight of each must be $\frac{1}{2}$ L; if three, the weight of each must be $\frac{1}{3}$ L; and so on for any number.

By considering this attentively, we may infer, without farther investigation, what will be the undulations of all the different plates of air in a pipe stopped at both ends. We have only to compare it with a cord similarly divided and loaded. Increase the number of loaded points, and diminish the load on each, continually—it is evident that this terminates in the case of a simple cord, with its matter uniformly diffused; and a simple pipe, with its air also uniformly diffused over its whole length.

Therefore, if we take an elastic cord, and stretch it by such a weight that the extending weight may bear the same proportion to the accelerating force acting on the whole matter concentrated in its middle point, which the elasticity of the air bears to its accelerating force acting on the whole matter concentrated at the mouth of an open pipe, sounding its fundamental note, the cord and the air will vibrate in the same time. Moreover, since the proportion between the vibrations of a cord so constituted, and those of a cord having its matter uniformly diffused, is the same with the proportion between the undulations in a pipe so constituted, and those of a pipe in which the air is uniformly diffused—it is plain that the vibrations of the cord and of the pipe in their natural state will also be performed in equal times.

We look on this as the easiest way of obtaining a distinct perception of the authority on which we rest our knowledge of the absolute number of undulations of the air in a pipe of given length. It may be obtained directly; and Daniel Bernoulli, Euler, and others, have given very elegant solutions of this problem, without having recourse to the analogy of the vibrations of cords and undulations of a column of air. But it requires more mathematical knowledge than many readers are possessed of who are fully able to follow out this analogical investigation.

Let us therefore compare this theory with experiment. What we call an open pipe of an organ is the same which we, in this theory, have considered as a pipe open at both ends; for the opening at the foot, which the organ builders call the VOICE of the pipe, is equivalent to a complete opening. The aperture, and the sharp edge which divides the wind, may be continued all round, and the wind admitted by a circular slit, as is represented in fig. 10. We have tried this, and it gives the most brilliant and clear tones we ever heard, far exceeding the tones of the organ. An open organ pipe, therefore, when sounding its fundamental note, undulates with one node in its middle, and its undulations are analogous, in respect of their mechanism, with the vibrations of a wire of the same length, and the same weight, with the column of air in the pipe, and stretched by a weight equal to that of a column of the same air, reaching to the top of a homogeneous atmosphere, or equal to the weight of a column of mercury as high as that in the barometer.

Dr Smith (see *Harmonics*, 2d edit. p. 193.) found that a brass wire whose length was 35,55 inches, and weight 31 troy grains, and stretched by 7 pounds avoirdupois or 49000 grains, was in perfect unison with an open organ pipe whose length was 86,4 inches.

Now 86,4 inches of this wire weighs 75,34 grains. When the barometer stands at 30 inches, and the thermometer at 55° (the temperature at the time of the experiment), the height of a homogeneous atmosphere is 332640 inches. This has the same proportion to the length of the pipe which the pressure of the atmosphere has to the weight of the column of air contained in the pipe.

Now 86,4 : 332640 = 75,34 : 290060. This wire, therefore, should be stretched (if the theory be just) by 290060 grains, in order to be unison with the other wire, and we should have $35{,}55^2 : 86{,}4^2 = 49000 : 290060$

But, in truth, - $35{,}55^2 : 86{,}4^2 = 49000 : 289430$

The difference is - - - - - 630

The error scarcely exceeds $\frac{1}{500}$, and does not amount to an error of one vibration in a second.

We must therefore account this theory as accurate, seeing that it agrees with experiment with all desirable exactness.

We

We may alfo deduce from it a very compendious rule for determining the abfolute number of aereal pulfes made by an open pipe of any given length. When confidering the vibrations of cords, we found that the number of vibrations made in a fecond is $\sqrt{\frac{386\,E}{LW}}$, where E is the extending weight, W the weight of the cord, and L its length. Let H be the height of a homogeneous atmofphere. We have its weight $= \frac{HW}{L}, = E$. Therefore fubftituting $\frac{HW}{L}$ for E in the above formula, we have the number of aereal pulfes made per fecond $= \sqrt{\frac{386\,H}{L^2}}$, or $= \frac{\sqrt{386\,H}}{L}$. Now $\sqrt{386}\,H$, computed in inches, is 11331. Therefore, if we alfo meafure the length of the pipe L in inches, the pulfes in a fecond are $= \frac{11331}{L}$. Thus, in the cafe before us, $\frac{11331}{86,4} = 131,12$, or this pipe produces 131 pulfes in a fecond. Dr Smith found by experiment that it produced 130,9, differing only about $\frac{1}{5}$th of a pulfe.

We fee that the pitch of a pipe depends on the height of the homogeneous atmofphere. This may vary by a change of temperature. When the air is warmer it expands, and the weight of the induced column is leffened, while it ftill carries the fame preffure. Therefore the pitch muft rife. Dr Smith found his organ a full quarter tone higher in fummer than in winter. The effect of this is often felt in concerts of wind inftruments with ftringed inftruments. The heat which fharpens the tone of the firft flattens the laft. The harpfichord foon gets out of tune with the horns and flutes.

Sir Ifaac Newton, comparing the velocity of found with the number of pulfes made by a pipe of given length, obferved that the length of a pulfe was twice the length of the open pipe which produced it. Divide the fpace paffed over in a fecond by the number of pulfes, and we obtain the length of each pulfe. Now it was found that a pipe of 21,9 inches produced 262 pulfes. The velocity of found (as computed by the theory on which our inveftigation of the undulations in pipes proceeds) is 960 feet. Now $\frac{960 \times 12}{262} = 44$ inches very nearly, the half of which is 22, which hardly differs from 21,9. The difference of this theoretical velocity of found, and its real velocity 1142 feet per fecond, remains ftill to be accounted for. We may juft obferve here, that when a pipe is meafured, and its length called 21,9 we do really allow it too little. The voice hole is equivalent to a portion, not inconfiderable of its length, as appears very clearly from the experiments of Mr Lambert on a variable pitch pipe, and on the German flute, recorded in the Berlin Memoirs for 1775. He found it equivalent to $\frac{1}{6}$th; and this is fufficient for reconciling thefe meafures of a pulfe with the real velocity of found.

The determination which we have given of the undulations of air in an organ pipe is indirect, and is but a fketch of the beautiful theory of Daniel Bernoulli, in which he ftates with accuracy the precife undulation of each plate of air, both in refpect of pofition, denfity, velocity, and direction of its motion. It is a pleafure to obferve how the different equations coincide with thofe which exprefs the vibrations of an elaftic cord. But this would have taken up much room, and would not have been fuited to the information of many curious readers, who can eafily follow the train of reafoning which we have employed.

Mr Bernoulli applies the fame theory to the explanation of the undulations in flutes, or inftruments whofe founds are modified by holes in the fides of the pipe. But this is foreign to our purpofe of explaining the mufic of the trumpet. We fhall only obferve, that a hole made in that part of a pipe where a node fhould form itfelf, in order to render practicable the undulations competent to a particular note, prevents its formation, and in its place we only get fuch undulations (and their correfponding founds) as have a loop in that place. The intelligent reader will perceive that this fingle circumftance will explain almoft every phenomenon of flutes with holes; and alfo the effects of holes in inftruments with a reed voice, fuch as the hautboy or clarionette.

We now fee that the found or mufical pitch of a pipe is inverfely as its length, in the fame manner as in ftrings. And we learn, by comparing them, that the found of a trumpet has the fame pitch with an open organ pipe of the fame length. A French horn, 16 feet long, has the found C *fa ut*, which is alfo the found of an open flute-pipe of that length.

The Trombone, great trumpet, or Sackbut, is an old inftrument defcribed by Merfennus, and other authors of the laft century. It has a part which flides (air-tight) within the other. By this contrivance the pitch can be altered by the performer as he plays. This is a great improvement when in good hands; becaufe we can thus correct all the falfe notes of the trumpet, which are very offenfive, when they occur in an emphatical or holding note of a piece of mufic. We can even employ this contrivance for filling up the blanks in the lower octaves.

We muft not take leave of this fubject without taking notice of another difcovery of Mr Bernoulli's, which is exceedingly curious, and of the greateft importance in the philofophy of mufic.

Artifts had long ago obferved that the deep notes of mufical inftruments are fometimes accompanied by their harmonic founds. This is moft clearly perceived in bells, fome of which give thefe harmonics, particularly the 12th, almoft as ftrong as the fundamental. Muficians, by attending more carefully to the thing, feem now to think that this accompaniment is univerfal. If one of the fineft founding ftrings of the bafes of a harpfichord be ftruck, we can hear the 12th very plainly as the found is dying away, and the 17th major is the laft found that dies away on the ear. This will be rendered much more fenfible, if we divide the wire into five parts, and at the points of divifion tie round it a thread with a faft knot, and cut the ends off very fhort. This makes the ftring falfe indeed by the unequal loading; but, by rendering thofe parts fomewhat lefs moveable by this additional matter, the portions of the wire between thefe points are thus jogged, as it were, into fecondary vibrations, which have a more fenfible proportion to the fundamental vibration. This is ftill more

fenfible

fensible in the found of the ftrings of a violincello when fo loaded; but we muft be careful not to load them too much, becaufe this would fo much retard the fundamental vibration, without retarding the fecondary vibrations, that both cannot be maintained together. (*N. B.* This experiment always produces a beat in the found).—Liftening to a fine founding flute pipe of the organ, we can alfo very often perceive the fame thing. Mr Rameau, and moft other theorifts in mufic, now affert that this is the effence of a mufical found, and *neceffarily* exifts in all of them, diftinguifhing them from harfh noifes. Rameau has made this the foundation of his fyftem of mufic, afferting that the pleafure of harmony refults from the fuccefsful imitation of this harmony of Nature, (fee Music, *Encycl.*). But a little logic fhould convince thefe theorifts that they muft be miftaken. If a note is mufical becaufe it has thefe accompaniments, and by this compofition alone is a mufical note, what are thefe harmonics? Are they mufical notes? This is granted. Therefore they have the fame compofition; and a mufical note muft confift at once of every poffible found; yet we know that this would be a jarring noife. A little mathematics, too, or mechanics, would have convinced them. A fimple vibration is furely a moft poffible thing, and therefore a fimple found. No, fay the theorifts; for though the vibration of the cord may be fimple, it produces fuch undulations in the air as excite in us the perception of the harmonics. But this is a mere affertion, and leaves the queftion undecided. Is not a fimple undulation of the air as poffible as the fimple vibration of a cord?

It is, however, a very curious thing, that almoft all mufical founds really have this accompaniment of the octave, 12th, double octave, and 17th major; for thefe are the harmonics that we hear.

The jealoufy of Leibnitz and of John Bernoulli, and their unfriendly thoughts refpecting all the Britifh mathematicians, made John Bernoulli do every thing in his power to leffen the value of Dr Taylor's inveftigation of the vibration of a mufical cord. Taylor gave him a good opportunity. Perhaps a little vain of his inveftigation of this abftrufe matter, he thought too much of it. He affirmed that the harmonic curve was the effential form of a ftring giving a mufical note. This was denied without knowing at firft whether it was true or falfe. But as the analytic mathematics improved, it was at length found that there are an infinity of forms into which an elaftic cord can be thrown, which are confiftent both with ifochronous vibrations, whether wide or narrow, and alfo with the condition of the whole cord becoming a ftraight line at once. Euler, D'Alembert, and De la Grange, have profecuted this matter with great ingenuity, and it is one of the fineft problems of the prefent day.

Daniel Bernoulli, of a very different caft of mind from his illuftrious friends, admired both Newton and Taylor; and fo far from wifhing to eclipfe Dr Taylor by the additions he had made to his theory, tried whether he could not extend Taylor's doctrine as far as the author had faid. When he took a review of what he had done while explaining the partial vibrations of mufical cords, he thought it very poffible that while a cord is vibrating in three portions, with two nodes or points of reft, and founding the 12th to its fundamental, it might at the fame time be alfo vibrating as a fimple cord, and founding its fundamental note. It was poffible, he thought, that the three portions might be vibrating between the four points with a triple frequency, while the two middle nodes were vibrating acrofs the ftraight line between the two pins; and thus the vibrating cord might be a moveable axis, to which the rapid vibrations of the three parts might always be referred. This was very fpecious, and when a little more attentively confidered, became more probable; for if the cord $ApBqCrD$ (fig. 8.) be vibrating as a 12th to its fundamental AD, the points B and C are in equilibrio. If therefore thefe two points be laid hold of by hooks, and be drawn afide to β and γ, while the ftring is yet vibrating, this fhould not hinder the vibrations. If the hooks be annihilated in an inftant, the whole fhould vibrate between A and D; and this fhould be in a way very different from the fimple vibration. The queftion now is, will the cord *continue* to vibrate with the loops $\beta s \gamma$, $\beta q \gamma$, &c. in the 900th part of a fecond (for inftance), while the whole ftring vibrates from $A \beta \gamma D$ to $A \beta' \gamma' D$ in the 300th part of a fecond? or will it at once acquire the form of the fimple harmonic curve? The cafe in which it is moft likely to take the latter mode of vibration is when the points β and γ are let go at the inftant that each portion of the ftring is in the middle of its vibration, and therefore forms the line $A \beta \gamma D$. But a moment's confideration will fhew us that it cannot do this; for at that inftant the point v, for inftance, which had come from q, is moving outwards with a moft rapid motion, and therefore will continue to go outward, while β and γ are approaching the axis. The point w, on the contrary, is at this moment approaching the axis with a motion equally rapid. They cannot therefore all come to the axis at once, and the vibration muft differ greatly from a fimple one. On the other hand, let it be fuppofed that both fpecies of vibrations can be preferved, and that, at the moment of letting go the points β and γ, the cord has the form $Am\beta q\gamma nD$. Then, when β and γ have come to B and C, having made $\frac{1}{4}$ a vibration, the point m will be in the axis, having made a vibration downward, and a half vibration upwards, q, in like manner, is in the axis, having made a whole vibration upwards, and half a vibration downwards. n is like m. Thus the whole comes to the axis at once; and in fuch a manner, that if the points B and C were inftantly ftopped, the three portions would continue their partial vibrations without any new effort. The refult of this compound vibration muft be a compound pulfe of air, which will excite in us the perception of the fundamental found and of its 12th. The confequence will be the fame if the points β and γ are ftopped any where fhort of the axis; and therefore (faid Bernoulli) the ftring will really vibrate fo if not ftopped at all.

But this was refufed by Euler, who obferved that in the points β and γ of contrary flexure, having no curvature, there can be no accelerating force. This caufed Bernoulli to attempt a direct inveftigation, examining minutely the curvatures and accelerating forces in the different points.

He had the pleafure of finding that the accelerating forces arifing from the curvature in every point, were precifely fuch as would produce the accelerations neceffary in thofe points for performing the motion that was

was required. And he exhibited the equations expressive of the state of the cord in all these points. And, on the faith of these equations, he restored the Taylorean curve to the rank which its inventor had given it; and he asserted that in every musical vibration the cord was disposed in a harmonical curve either simple or compound. He farther shewed that the equations which Euler and D'Alembert had given for the musical cord (at least in the cases which they had published) were included in his equations, and that their equations only exhibited its momentary states, while his own equations shewed the physical connection of them all; which is, that the whole cord forms a harmonic curve between the two fixed pins, while its different portions form subordinate harmonic curves on the first as an axis. Euler and D'Alembert, although they acknowledge this in the particular cases which they had taken as examples, on account of their simplicity, still insist that no subordinate harmonic vibrations can correspond to all the states of an elastic cord which their equations exhibit as isochronous and permanent. Mr Bernoulli's death put an end to the controversy, and the question (considered as a general theory) is perhaps still undecided. It may very probably be true, that as a simple vibration may be permanent which never has the form of the simple harmonic described by Dr Taylor, so a vibration may exist compounded of such vibrations, and therefore not expressible by any equation deduced from the Taylorean curve.

But, in the mean time, Mr Bernoulli has made the most beautiful discovery in mechanics which has appeared in the course of the last century, and has explained the most curious phenomenon of continued sounds, *viz.* the *almost universal* accompaniment of the harmonic notes of any fundamental sound. For this *susceptibility* of compounded variation is not confined to a 12th, but is equally demonstrable of every other harmonic. Nay, it is evident that the same simple vibration of a cord may furnish a moveable axis to more than one harmonic. For as the simple vibration can have a subordinate harmonic vibration superinduced upon it, so may this compounded vibration have another superinduced on it, and so on to any degree of composition. And farther, as Mr Bernoulli has shewn the complete analogy between the accelerations of the different points of an elastic cord and of the corresponding plates of a column of air, it legitimately follows that all the consequences which we can easily deduce, respecting the vibrations of an elastic cord, may be affirmed respecting the undulations of a column of air in a pipe. Therefore this accompaniment of the harmonics must not be confined to the music of strings and bells, but equally obtains in the music of wind instruments. And thus the doctrine becomes universal.

Mr Bernoulli did not think it enough to shew that these compound vibrations are possible. He endeavours to shew that this accompaniment must be frequent. He illustrates this very prettily, by supposing that a toothed wheel is turned round, and rubs with its teeth on an elastic cord. If the successive dropping of the teeth keep exactly pace with such vibrations as the cord can take and maintain by its elasticity, these will certainly be formed on it. If the intervals do not *exactly* correspond, a little reflection will shew that the agitation which the cord acquires will approximate to those which it can maintain: and if when they are exactly so in any place of it, and the wheel be in that instant removed, this vibration will remain and diffuse itself through the rest of the cord; so that the very last dying quiver (so to speak) will be harmonic. Every *harmonic* agitation tends, by the very nature of the thing, to continue, while those that are incompatible really *do* destroy each other; and the very last must be the remainder or superplus of such as could continue, over those which destroyed each other. Accordingly, the harmonic notes of wires are always most distinctly heard as the sound is dying away.

There is no occasion now to say any thing about the fallacy of Rameau's *Generation Harmonique* as a theory of musical pleasure. Our harmonies please us, not because a sound is accompanied by its harmonics, but because harmonics please. His principle is therefore a tautology, and gives no instruction whatever. His theory is a very *forced* accommodation of this principle to the practice of musicians, and taste of the Public. He is exceedingly puzzled in the case of the *sousdominante*, or 4th of the scale, and the 6th where there is no resonance. He says that these notes, "fremissent, quoiqu' elles ne resonnent pas." But this misleads us. They do not resound; because a 4th and a 6th cannot be produced at all by dividing the chord. They tremble; because the false 4th and false 6th are very near the true ones, and the true 4th and 6th would both tremble and resound, if they were made false. A string will both tremble and resound, if very nearly true, as any one observes the 12th and 17th on a harpsichord tremble and resound very strongly, though they are tempered notes. The whole theory is overturned at once by tuning the 4th false, so as to correspond to an aliquot division of the cord. It will then resound; and if this had happened to be agreeable, it would have been catched at as the sousdominant.

The physical cause of the pleasure of harmonic sounds is yet to seek, as much as our choice of those notes for melody which give us the best harmony (see Temperament, *Suppl.*). We have no hesitation in saying that, with respect to our choice, the two are quite independent. Thousands enjoy the highest pleasure from melody who never heard a harmonious sound. All the untaught singers, and all simple nations, are examples. They not only fix on certain intervals as the steps of their tunes, but are disgusted when other steps are taken. Nor do we hesitate, for the very same reasons, to say that the rules of accompaniment are dependent on the cantus or air, and by no means on the fundamental bass of Rameau. The dependence assumed by him, as the rule of accompaniment, would, if properly adhered to, according to his own notions of the comparative values of the harmonics, lead to the most fantastic airs imaginable, always jumping by large intervals, and altogether incompatible with graceful music. The rules of modulation which he has squeezed out of his principle, are nothing but forced, very forced, accommodations of a very vague principle to the current practice of his contemporaries. They do not suit the primitive melodies of many nations, and they have caused these national musics to degenerate. This is acknowledged by all who are not perverted by the prevailing habits. We have heard, and could write down, some most enchanting lullabies of simple peasant women, Musical Trumpet.

men, possessed of musical sensibility, but far removed, in the cool sequestered vale of life, from all opportunities of stealing from our great composers. Some of these lullabies never fail to charm, even the most erudite musician, when sung by a fine flexible voice: but it would puzzle Mr Rameau to accompany them *secundum artem*.

We conclude this subject by describing a most beautiful and instructive experiment.

Mr Watt, the celebrated engineer, was amusing himself (about the year 1765) with organ building, and invented a monochord of continued sound, by which he could tune an organ with mathematical precision, according to any proposed system of temperament. It consisted of a covered string of a violincello, sounding by the friction of an ivory wheel. The instrument did not answer Mr Watt's purpose, by reason of the dead harshness of its tone, and a flutter in the string by the unequal action of the wheel. But Mr Watt was amused by observing the string frequently taking, of its own accord, points of division, which remained fixed, while the rest was in a state of strong vibration. The instrument came into the possession of the writer of this article. He soon saw that it gave him an opportunity of making all the experiments which Bernoulli could only relate. When the string was kept in a state of simple vibration, by a very uniform and gentle motion of the wheel, if its middle point was then gently touched with a quill, this point immediately stopped, but the string continued to vibrate in two parts, sounding the octave: And this it continued to do, however strong the vibrations were rendered afterwards by increasing the pressure and velocity of the wheel. The same thing happened if the string was gently touched at one-third. It instantly divided itself into three parts, with two nodes, and sounded the 12th. In the same manner the double octave, the 17th, and all other harmonics, were produced and maintained.

But the prettiest experiment was to put something soft, such as a lock of cotton, in the way of the wide vibrations of the cord, at one-third and two-thirds of its length, so as to disturb them when they became very wide. When this was done, the string instantly put on the appearance of fig. 8. performing at once the full vibration competent to its whole length, and the three subordinate vibrations, corresponding to one-third of its length, and sounding the fundamental and the 12th with equal strength. In this manner all the different accompaniments were produced at pleasure, and could be continued, even with strong sounds. And it was amusing to observe, when the wheel was strongly pressed to the string, and the motion violent, the nodes would form themselves on various parts of the string, running from one part to another. This was always accompanied with all the jarring sounds which corresponded to them.

When the string was making very gentle, simple vibrations, and the wheel hardly touching it, if a violincello was made to sound the 12th very strongly in its neighbourhood, the string instantly divided itself, and vibrated in unison, frequently retaining its simple vibration and fundamental tone. We recommend this experiment to every person who wishes to make himself well acquainted with the mechanism of musical sounds. He will see, in a most sensible and convincing manner, how a single string of the Æolian harp gives us all the changes of harmony, sliding from one sound to another, according as it is affected in its different parts by an irregular breeze of wind. The writer of this article has attempted to regulate these sweet harmonic notes, and to introduce them into the organ. His success has been very encouraging, and the sounds far exceed in pathetic sweetness any that have yet been produced by that noble instrument. But he has not yet brought them fully under command, nor made them strong enough for any thing but the softest chamber music. Other necessary occupations prevent him from giving the attention to this subject that it deserves. He recommends it therefore to the musical instrument makers as richly deserving their notice. His general method was this: A wooden pipe is made, whose section is a double square. A partition in the middle divides it into two pipes, along side of each other. One of them communicates with the foot and wind chest, and is shut at the upper end. The other is open at the upper, and shut at the lower end. In the partition there is a slit almost the whole length, and the sides of this slit are brought to a very smooth chamfered or feather edge. A fine catgut is strained in this slit, so as almost to touch the sides. It is evident that when the wind enters one pipe by the foot, it passes through the slit into the other, and escapes at the top, which is open. In its passage it forces the catgut into motion, and produces a musical note, having all the sweetness of the Æolian harp. The strength of sound may be increased by increasing the body of air which is made to undulate. This was done by using, instead of catgut, very narrow silk tape or ribband varnished: but the unavoidable raggedness of the edges made the sounds coarse and wheesing. Flat silver wire was not sufficiently elastic; flat wire, used for watch balance springs, was better, but still very weak sounded. Other methods were tried, which promised better. A thin round plate of metal, properly supported by a spring, was set in a round hole, made in another plate not so thin, so as just not to touch the sides. The air forced through this hole made the spring plate tremble, dancing in and out, and produced a very bold and mellow sound.—This, and similar experiments, are richly worth attention, and promise great additions to our instrumental music.

Musical Trumpet ‖ Truro.

TRURO, a town of Nova-Scotia, situated in Halifax county, at the head of the Basin of Minas, opposite to, and 3 miles southerly of, Onslow; 40 miles N. by W. of Halifax, and 40 from Pictou. It was settled by the North-Irish, some Scotch, and the descendants of North-Irish. Through this town runs the river called by the Indians Shubbenacadie, navigable for boats to within 9 miles of Port Sackville.—*Morse*.

TRURO, a township of Massachusetts, situated in Barnstable county, lies between lat. 41 57, and 42 4 N. and between long. 70 4 and 70 13 W. It is on the easternmost part of the peninsula of Cape Cod, 57 miles S. E. of Boston, in a straight line, but as the road runs it is 112, and 40 from the court-house of Barnstable. It is the *Pamet* of the Indians, and after its settlement in 1700 was some time called *Dangerfield*; it was incorporated under its present name in 1709, and contains 1,193 inhabitants. Only one family of Indians remained a few years since, and lived on *Pamet Point*. In the valley called *Great Hollow*, a creek sets up from the bay, at the mouth of which is a tide harbour. The other landing-places are of small note.

Pamet Harbour is about 100 yards wide at the mouth, but is wider within; and if repaired would be of public utility. It lies above 3 leagues S. E. of Cape Cod harbour. The hill on which the meeting-houfe ftands branches from the high land of Cape-Cod, well known to feamen. The mountain of clay in Truro, in the midft of fandy hills, feems to have been placed there by the God of Nature, to ferve as a foundation for a light-houfe, which if erected might fave the lives of thoufands, and millions of property. The foil of Truro is, in moft places, fandy, like Provincetown; and the inhabitants derive their principal fubfiftence from the fea, which here abounds with vaft variety of fifh. Great part of their corn and vegetables are procured from Bofton and the neighbouring towns. Two inhabitants of Truro, Captains David Smith and Gamaliel Collings, were the firft who adventured to Falkland Iflands in purfuit of whales. This voyage, which was crowned with fuccefs, was undertaken in 1774, by the advice of Admiral Montague of the Britifh navy. The whalemen of Truro now vifit the coaft of Guinea and Brazil. Many of the mafters of fhips employed from Bofton and other ports, are natives of Truro. The elderly men and fmall boys remain at home to cultivate the ground; the reft are at fea two-thirds of the year. The women are generally employed in fpinning, weaving, knitting, &c.—*ib.*

TRUXILLO, a bay, harbour, and town, at the bottom of St Giles's Bay, on the coaft of Honduras, in the gulf of that name. The bay is about 6 miles broad, being deep and fecure, and defended by a caftle; but it has little trade. The town ftands about a league from the North Sea, between two rivers, the mouths of which, with fome iflands before them, form the harbour. The country is exceedingly fruitful in corn and grapes, and notwithftanding the heat of the climate, very populous. The city is defended by a thick wall towards the fea, and is inacceffible but by a narrow, fteep afcent. The caftle joins to the wall, and ftands on a hill. Behind the city are high mountains. It lies 300 miles N. E. of Amapalla. N. lat. 15 20, W. long. 85 56.—*ib.*

Truxillo, the firft diocefe in the audience of Lima, in Peru.—*ib.*

Truxillo, a bay or harbour, and one of the principal cities of the province of the fame name in Peru, is 11 leagues from Chocope, and 80 N. W. of Lima; and according to Ulloa, the city lies in lat. 8 6 3 S. and long. 77 30 W. It ftands in the valley of Chimo, on a fmall river, about half a league from the fea; is furrounded with a brick wall, and from its circuit may be claffed among cities of the third order. Two leagues to the northward is the port of Guanchaco, the channel of its trade. The houfes make an elegant appearance, being generally of brick, with ftately balconies and fuperb porticos.—*ib.*

Truxillo, or *Noftra Seniora de la Paz*, a town of New-Granada (Venezuela) and Terra Firma, in S. America, 125 miles fouth of Maracaibo Lake; on the fouthernmoft bank of which lake is a village, called Truxillo, dependent on this city. The city is in lat. 9 21 N. and long. 69 15 W.—*ib.*

TRYON *Mountains*, in N. Carolina, lie N. W. of the town of Salifbury, on the borders of the State of Tenneffee.—*ib.*

Tfchirnhaus.

TSCHIRNHAUS, (Ehrenfred Walther Von), a name well known in the republic of letters, and one of the ornaments of the 17th century, was born April 10, 1651, at Kiflingfwald near Gorlitz in Upper Lufatia. His father was Erneft Chriftopher Von Tfchirnhaus, Baron Kiflingfwald and Stolzberg, and Obernfchonfeld, privy counfellor, and in various offices of rank under the Electors George I, and II. of Saxony, the firft of whom honoured him with the diftinction of the gold chain and portrait, as a mark of his fenfe of his merits and fervices. The mother of the young Von Tfchirnhaus was Maria Stirling, daughter of *Baron Stirling et Achil*, Stirling of Achil, or Achyle, in Scotland, an old and refpectable family, as appears by an epitaph which the Duke Chriftian, brother of the Elector George II. infcribed on the tomb of Johan Albert Stirling of Achil, in the cathedral of Marckfpurg. This gentleman had been prefident of the fenate of the electorate, privy counfellor, director of the impofts, and mafter of horfe to the Prince, and had, by his faithful and ufeful fervices, acquired his higheft efteem.

E. W. Von Tfchirnhaus was born, as has been obferved, at Kiflingfwald, the ufual refidence of the family, and poffeffed by it during more than 300 years. The family came originally from Bohemia, and appears to have been confiderable, feeing that, from the earlieft accounts of it in Lufatia, the Barons of Kiflingfwald are generally found in the moft refpectable civil offices.

The figure which Baron Von Tfchirnhaus, the fubject of this relation, has made in the fcientific and political world, makes it fuperfluous to fay that his early years were well employed. Quick apprehenfion, a clear perception of the fubject of his thoughts, and the moft ardent and infatiable thirft for knowledge, diftinguifhed him during his academical education. When 17 years of age, he was fent to Leyden. In 1672 all ftudy was interrupted in Holland by the din of war; and Mr Van Tfchirnhaus left the univerfity for the camp. His knowledge in mathematics, mechanics, and all phyfical fcience, found ample room in the military fervice for fhewing the importance of thofe fciences; and Tfchirnhaus fo diftinguifhed himfelf by his fervice in this way, that Baron Nieuland, a general officer of great merit, and at the fame time an accomplifhed fcholar, took delight in pufhing him into every fervice where he could fhew himfelf and his talents.

After two years fervice, he returned to his father's; but finding little to intereft him in the life of a mere country gentleman, and ftill burning with the fame thirft of knowledge, he prevailed on his father to allow him to travel. His younger brother George Albrecht Von Tfchirnhaus, Baron Obernfchonfeld, which he inherited from his grandfather Stirling, loved him with the warmeft affection, and fupplied him liberally with what was required for his appearance every where in a manner becoming his rank, and for fully gratifying his curiofity. He ufed often to fay, "Sorry was I to lofe the company of my dear brother, and I fometimes wifhed to accompany him; but not having his thirft for knowledge, I knew that his love for me would debar him of much happinefs, which I fhould thus have obftructed." *Felices animæ!* He went to Holland, from thence into England, France, Italy, Sicily, Malta, Greece.—Returning through the Tyrol, he met his brother at Vienna, where both were in great favour at the court of Leopold.

Tſchirnhaus.

Leopold. Wherever he went, he made himſelf acquainted with the moſt eminent in all departments of ſcience, living with them all in the mutual exchange of diſcoveries and of kind offices. In Holland he was intimate with Huyghens and Hudde; in England with Newton, Wallis, Halley, and Oldenburgh; in France, among a people who more ſpeedily contract acquaintance, there was not a man of note with whom he did not cultivate an active acquaintance—and, fortunately, Leibnitz then lived at Paris: in Italy, he was particularly careſſed by Michaeli, ſoon after Cardinal; and was in the cloſeſt correſpondence with Kircher. His enjoyments, however, were derived ſolely from the communications of the moſt eminent; his curioſity was directed to every thing, and wherever he ſaw an ingenious artiſan, he was eager to learn from him ſomething uſeful. In 1682, when at Paris for the third time, he communicated to his friends his celebrated theory of the cauſtic curves, which marked him out as a valuable acquiſition, and he was elected a member of the Royal Academy of Sciences, which was then reformed by the great miniſter Colbert, and the moſt illuſtrious in all nations were picked out for its ornaments. There he found himſelf ſeated with Leibnitz, Huyghens, John Bernoulli, &c.

After twelve years employed in viſiting Europe, he returned home: but after a ſhort ſtay, went to Flanders, and prepared to publiſh his work, intitled *Medicina Mentis;* of which the ſubject may almoſt be gueſſed, from the way in which he had exerciſed his own mind. Having the moſt exalted notions of the intellectual and moral nature of man, he thought that the continual ſupply of information was as neceſſary as the continual ſupply of food. And his great principle was TO ENLIGHTEN. This work was committed to the care of ſome friends, and did not appear till 1687, at Amſterdam. A ſecond edition appeared at Leipſic in 1695.

Finding now that his moderate fortune was inſufficient for the great public projects he had in view, he ſought for aſſiſtance, and endeavoured to make friends by frequenting the court of the Elector at Dreſden. He ſoon became a favourite of his Princes, George the II. and III. and was appointed to active offices of great reſponſibility. By the orders and encouragement of the Elector, then king of Poland, he introduced into his native country the firſt manufacture of glaſs; and his project ſoon throve to ſuch a degree, that not only Saxony was ſupplied, but they even began to export the finer kinds of white glaſs for windows; in which manufacture Saxony ſtill excels. It was in the courſe of experiments for improving this manufacture that Tſchirnhaus made the celebrated great burning glaſſes which ſtill bear his name. He made two of theſe lenſes, and gave one to the Emperor, and the other to the Academy of Paris. He was eager to improve the art of forming and poliſhing optical glaſſes; and in the proſecution of the theory on which their performance depends, he made ſome beautiful diſcoveries in the department of pure geometry. It is well known that all the ſciences are allied, and of a family, and that eminence in one is ſeldom attainable without the aſſiſtance of others. His preſent purſuits led him to the ſtudy of chemiſtry, which he proſecuted with the ſame ardour which he exhibited in every thing he undertook. But all the while, mathematics, and eſpecially geometry, was his favourite ſtudy; and he was anxious to make the ſame advances in the general paths of mathematical inveſtigation which he thought he had made in the general laws of material nature. He apprehended that only bye paths were yet known, and that many things were yet inacceſſible; becauſe we had not yet found out the great roads from which thoſe branches were derived. He was of Des Cartes's opinion, that the true road in mathematics muſt be an eaſy one, except in caſes which were, in their own nature, complicated. Very early, therefore, he began writing on mathematical ſubjects, always continuing his general views of the ſcience, and his endeavours to ſyſtematiſe the ſtudy; but, at the ſame time, beſtowing a very particular attention on any branch which chanced to intereſt him; each of theſe his epiſodical ſtudies in mathematics deſerves the name of a department of the ſcience. This is the caſe with his theory of cauſtic curves, with his method of tangents, and his attempt to free Leibnitz's calculus from all conſideration of infiniteſimal quantities. Mr Tſchirnhaus ſeldom gave himſelf any trouble with a particular problem. In all his mathematical performances, there is an evident connection with ſomething which he conſidered as the great whole of the ſcience; and the manner of treating the different queſtions is plainly accommodated to a ſyſtem in his thoughts. This he intended as the third part of the Medicina Mentis; and, having nearly completed the ſecond, he had propoſed theſe as the occupation of the enſuing winter (1708-9). But his death, which may be called premature, has deprived the world of theſe, and other beneficent and uſeful labours.

Mr Von Tſchirnhaus was of the moſt mild and gentle diſpoſition, as was well known to all who enjoyed his acquaintance. This diſpoſition was ſo eminent in him, that ſcarcely any perſon ever ſaw him angry, or even much ruffled in his temper. He forgave injuries frankly and heartily, and often ſtood the friend (unknown) of thoſe who had wronged him. By ſuch conduct, he changed ſome enmities into the moſt ſteady and affectionate friendſhips. As an inquirer and an inventor, he had contentions with other claimants, and ſome diſputes about the legitimacy of his methods; as, for example, with Nicholas Fatio Duiller, who attacked Tſchirnhaus's method of tangents; and Preſtet and Rolle, who found fault with his expreſſion of equations of the third degree. But theſe were all friendly debates, and never carried him beyond the limits of gentlemanly behaviour. He began to diſpute with Ozanam about a quadratrix; but on being merely told that he was miſtaken, by P. Souciet, he immediately acknowledged his error, and corrected it.

Many original and important mathematical performances of Mr Von Tſchirnhaus are to be ſeen in the Leipſic Acts, in the Memoirs of the Academy of Sciences at Paris, and other literary journals. His happy generaliſation of Dr Barrow's theorem for the focus of a ſlender pencil of rays after reflection or refraction, and the theory of cauſtic curves, in which this terminates, both conſtitutes one of the moſt elegant branches of optical ſcience, and affords a rich harveſt of very curious and unexpected geometrical truths. The manner in which he notices the rough way in which his firſt and ſole miſtake in this theory was pointed out, is perhaps incomparable as an example of gentlemanlike reprehenſion, Tschirnhaus.

reprehension, and is a lesson for literati of all descriptions, highly valuable on account of the soft way in which it falls, while it is convincing as a mathematical theorem.

Tschirnhaus was the discoverer of the substance of which the celebrated Saxon porcelain is made, and of the manner of working it up; by which he established a manufacture highly profitable to his country, and has given us the finest pottery in the world. He never wearied in spreading useful knowledge; and the shops of our artisans of almost all kinds were supplied with books of instructions and patterns, many of them written by Mr Von Tschirnhaus, or under his inspection. Useful books of all kinds were translated out of foreign languages at his expense. Men of genius in the arts were enabled, through the encouragement of himself and his friends, and often by his pecuniary assistance, to bring their talents before the public eye. In short, he seemed at all times to prefer the public good to his own; and never felt so much pleasure as when he could promote science or the useful arts. He was as it were stimulated to this by an innate propensity. And as he was more desirous of *being* than of *appearing* the accomplished man, he was in no concern what notice others took of his services to the public. He even represents the desire of fame as hostile to the improvement either of science or morality, in his *Medicina Mentis*; a work which is acknowledged by all who knew him to be a picture of his own amiable mind. He lightly esteemed riches; and knew not what use they were of, except for providing the necessaries of life, and the means of acquiring knowledge. In perfect conformity to this maxim, he modestly, and with elegant respect, refused the ample presents made him by his affectionate sovereign; and when he was added to his cabinet council, he received the diploma, but begged and obtained to be free from the title. And when he presented his great burning glass to the Emperor, and got from him the dignity and insignia of Baron of the Empire, he pleaded for leave to decline it, requesting to keep the chain and portrait, which he always wore under his vest. He expended a very great portion of the ample revenue left him by his father in the service of his country, by promoting the useful arts and sciences.

Mr Von Tschirnhaus venerated truth above all things; saying, that those who thought any thing comparable with it were not the sons of God, but step children, and that the love of truth is the ruling affection in every man of a worthy heart. In a letter to an intimate friend, he said that, by the age of five-and-twenty, he had completely subdued the love of glory, of riches, and of worldly pleasures; and that at no time he had found it difficult to repress vanity, because he was every day conscious of having acted worse than he was certain that he might and should have done. He felt himself humbled in the sight of the All-perfect Judge.

Nor was all this the vain boast of a man averse to business, and possessed of an ample fortune, which permitted him, without inconvenience, to please his fancy in study, and in helping others with what to himself was superfluous. Such a character, though rare, may exist, without being the object of much respect. No: Mr Tschirnhaus was really a philosopher of the true stoic sect, in respect of fortitude of mind, while a good Christian in modesty and diffidence. In the last five years of his life he bore up under troubles, and embarrassments, and misfortunes in his family, which would have tried the mind of Cato himself. But in the midst of these storms he was unshaken, and preserved his serenity of mind. He was even sensible of this being a rare gift of Providence, and used frequently to express his thankfulness for a treasure so precious. He felt deeply his relation to the Author of Nature, and rejoiced in thinking himself subject to the providence of God. He said that he was fully persuaded that he would meet with perfect justice, and would therefore strive to perform his own part to the utmost of his power, that his future condition might be the more happy, and that he might in the mean time enjoy more satisfaction on reflecting on his own conduct. His lot, he said, was peculiarly fortunate: having such thirst for novelty, he would have been unhappy without an affluent fortune; and his own enjoyments encouraged neither vice nor idleness in himself or in the ministers to his pleasures.

This amiable person was of a constitution not puny, but not robust, and he had hurt it by too constant study. He feared no disease; thinking that he had a cure or an alleviation for all but one, namely, the stone and gravel. He had a dread of this, and laboured to find a preventative or a remedy. He thought that he had also done a great deal here; and describes in his *Medicina Corporis* a preparation of whey, which he said he used with great advantage to his health. But his precautions were in vain: He was attacked with the gravel, which, after three months suffering, brought on a suppression of urine. The physicians saw that his end approached; and finding him disregard their prescriptions, they quitted him. He treated himself (it is said judiciously) for some time, and with some appearance of success; but at last he saw death not far off. He dictated a letter to his Sovereign, thanking him for all his favours and kindness, and recommended his children to his protection. He never fretted nor complained; but frequently, with glistening eyes, expressed his warmest thanks to Providence for the wonderful track of good fortune and of happiness that he had enjoyed; and said that he also felt some satisfaction in the consciousness that some of this was owing to his own prudent conduct. He possessed his entire faculties to the last moment, and when he felt his spirit just about to depart, his last words were, "*Jö triumphé—Victoria!*" No longer able to speak, he made signs for what he wanted; and a little after, shutting his eyes, as if to sleep, he gently, and without a groan, yielded up his spirit, about four o'clock in the morning of the 11th of October 1708, aged 56.

His funeral was performed in a manner becoming his rank, and the body conveyed to the family vault. The Elector (King of Poland) defrayed the expense; for he would not allow his family to have any thing to do with the funeral of a man of so public a character, and so universally beloved.

The account of such a life as that of Baron Von Tschirnhaus would, at all times, make a pleasant and useful impression. In these our times, in the beginning of the 19th century, after society has availed itself of all the acquisitions in science and art, furnished by that ardent age of the world which this gentleman contributed to adorn; in an age when we boast of illumination unparalleled in history, and of improvements almost amount-

ing

ing to perfection; and in particular, of an emancipation from the prejudices which had obſcured our view of the chief good, and ſtifled public ſpirit—now, when we are ſo full of knowledge that it is running over on all hands, in volumes of inſtruction, how to make the world one happy family; in theſe bright days of philanthropiſm, can the public records of Europe exhibit a ſuperior character to that of Mr Von Tſchirnhaus, either in reſpect of wiſdom or of diſpoſition? Was he not a philanthropiſt, a ſincere lover of mankind? Was he not wiſe, in employing his great acquired knowledge as the means of direct and active beneficence, by limiting his exertions to the extent of thoſe circles where his own efforts would be effective? He did not write books, teaching others how to do good: he taught it by example; being determined that his own wiſhes to ſee men happier ſhould not fail by the want of ſuch wiſhes in others, even after he ſhould inſtruct them. He never allowed his inſatiable curioſity for freſh diſcoveries to interfere with the immediate turning to the good of his own country the knowledge he had already acquired. He probably never thought of improving the ſituation of the Chineſe or the Mexicans, finding that it required all his ample fortune, and all the intereſt and influence he could acquire, to do the good he wiſhed in Saxony. We doubt not but that he was equally attentive to the ſtill narrower circle of duties formed by his own family. We ſee that he was a dearly beloved brother; which could hardly be without his alſo being a loving brother and a dutiful ſon. The nature of the diſtreſſes which he experienced in his family, and the manner in which he behaved under them, ſhew him to have been an eminent Chriſtian moraliſt. With a modeſty that is unmatched by any one of the thouſands who have poured out inſtructions upon us during the laſt ten years, and a gracefulneſs which characteriſes the gentleman, his *Medicina Mentis* is offered to public notice, merely as an experimental proof that a certain way of thinking and acting is productive of internal quiet of mind; of great mental enjoyment, both moral and intellectual; and of peace, and the good will of thoſe around us: and that it did, in fact, produce a dutiful and comfortable reſignation to the unavoidable trials of human life. He pretends not to be greatly ſuperior in wiſdom to his neighbours, but merely tells how things ſucceeded with himſelf. He did not ſcruple, however, to publiſh to the world diſcoveries in ſcience, in which he had got the ſtart of others during that buſy period of ſcientific occupation: and theſe diſcoveries in mathematics were highly prized by the firſt men of the age; nor will the name of Tſchirnhaus, or his cauſtic curves, ever be forgotten.

We felt ourſelves obliged to the friend who took notice of the omiſſion of this gentleman's name, ſo eminent in the mathematical world, in the courſe of our alphabet; but when we looked into the memoirs of the Academy of Paris for 1709 for ſome account of him, what we there ſaw appeared ſuch a continual panegyric, that we could not take it as a fair picture of any real character. Looking about for more impartial information, we found in the *Acta Eruditorum*, Leipſ. 1709, the account of which the foregoing is an abſtract, except a particular or two which we have copied from an account in the Literary Journal of Breſlaw, by Count Herberſtein, whom we can ſcarcely ſuſpect of undue partiality, becauſe he had ſome diſputes with Mr Von Tſchirnhaus on mathematical ſubjects. May we not ſay, "the memory of this man is ſweet!"

TSHAMIE, the Indian name of a tree in the Northern Circars of Hindoſtan. It grows, ſays Dr Roxburgh, to be a pretty large tree, is a native of moſt parts of the coaſt, chiefly of low lands at a conſiderable diſtance from the ſea, and may be only a variety of *proſopis ſpicigera*, for the thorns are in this ſometimes wanting; flowers during the cold and beginning of the hot ſeaſons. *Trunk* tolerably erect, bark deeply cracked, dirty aſh colour. *Branches* irregular, very numerous, forming a pretty large ſhady head. *Prickles* ſcattered over the ſmall branches; in ſome trees wanting. *Leaves* alternate, generally bipinnate, from two to three inches long; pinnæ from one to four, when in pairs oppoſite, and have a gland between their inſertions. *Leaflets* oppoſite, from ſeven to ten pair, obliquely lanced, ſmooth, entire, about half an inch long, and one-ſixth broad. *Stipules* none. *Spikes* ſeveral axillary, filiform, nearly erect. *Bracts* minute, one-flowered, falling. *Flowers* numerous, ſmall, yellow, ſingle, approximated. *Calyx* below, five-toothed. *Filaments* united at the baſe. *Anthers* incumbent, a white gland on the apex of each, which falls off ſoon after the flower expands. *Style* crooked. *Stigma* ſimple. *Legume* long, pendulous, not inflated. *Seeds* many, lodged in a brown meally ſubſtance.

The pod of this tree is the only part uſed. It is about an inch in circumference, and from ſix to twelve long; when ripe, brown, ſmooth, and contains, beſides the ſeeds, a large quantity of brown meally ſubſtance, which the natives eat; its taſte is ſweetiſh and agreeable; it may therefore be compared to the Spaniſh *algaroba*, or locuſt tree. (*Ceratonia ſiliqua*, Linn.)

In compliance with Dr Kœnig's opinion, Dr Roxburgh calls this tree a *proſopis*; but as he thinks the antheral glands give it a claim to the genus *adenanthera*, we have retained the Indian name till its botanical claſſification ſhall be aſcertained by thoſe who have greater authority in the ſcience than we lay claim to.

TUAPE, the chief town of the diviſion of Senora, in New Mexico.—*Morſe.*

TUBAI, a ſmall iſland, one of the Society Iſlands, in the S. Pacific Ocean, is about 4 or 5 leagues to the N. by W. or N. N. W. from Bolabola. S. lat. 16 12, W. long. 151 44.—*ib.*

TUCAPEE, on the coaſt of Chili, and the W. ſide of S. America, is on the S. Atlantic Ocean, 10 leagues N. N. E. from Rio Imperial, and 10 to the iſland of Santa Maria, or St Mary.—*ib.*

TUCKABATCHEES, a town of the Creek nation of Indians.—*ib.*

TUCKAHOE *Creek*, in Maryland, Talbot county, a branch of Choptank river.—*ib.*

TUCKER (Abraham), Eſq; a curious and original thinker, was a gentleman of affluent fortune, and author of "The Light of Nature purſued," 9 vols 8vo; of which the five firſt volumes were publiſhed by himſelf in 1768, under the aſſumed name of "Edward Search, Eſq;" and the four laſt after his death, in 1777, as "The poſthumous Work of Abraham Tucker, Eſq; publiſhed from his manuſcript as intended for the preſs by the author." Mr Tucker lived at Betchworth-caſtle, near Dorking, in Surry; an eſtate which he purchaſed purchafed in the early part of his life. He married the daughter of Edward Barker, Efq; by whom he had two daughters; one of whom married Sir Henry St John, and died in his lifetime; the other furvived, and now lives at Betchworth-caftle. He loft his eyefight a few years before his death, which happened in 1775. To defcribe him as a neighbour, landlord, father, and magiftrate, it would be neceffary to mention the moft amiable qualities in each. It is unneceffary to add that he was very fincerely regretted by all who had the pleafure of his acquaintance, and who ftood connected with him in any of thofe relations.

Tucker (Jofiah, D. D.) well known as a political and commercial writer, was born at Langhorn, in Caermarthenfhire, in the year 1712. His father was a farmer, and having a fmall eftate left him at or near Aberyftwith, in Cardiganfhire, he removed thither; and perceiving that his fon had a turn for learning, he fent him to Ruthin fchool, in Denbighfhire, where he made fo refpectable a progrefs in the claffics, that he obtained an exhibition at Jefus College, Oxford. It is generally underftood that feveral of his journeys to and from Oxford were performed on foot, with a ftick on his fhoulder, and bundle at the end of it. Thus it might be faid by him, as by Simonides, "*Omnia mea mecum porto.*"

At the age of 23 he entered into holy orders, and ferved a curacy for fome time in Gloucefterfhire. About 1737 he became curate of St Stephen's church in Briftol, and was appointed minor-canon in the cathedral of that city. Here he attracted the notice of Dr Jofeph Butler, then Bifhop of Briftol, and afterwards of Durham, who appointed Mr Tucker his domeftic chaplain. By the intereft of this prelate Mr Tucker obtained a probendal ftall in the cathedral of Briftol; and on the death of Mr Catcott, well known by his treatife on the Deluge, and a volume of excellent fermons, he became rector of St Stephen. The inhabitants of that parifh confift chiefly of merchants and tradefmen; a circumftance which greatly aided his natural inclination for commercial and political ftudies.

When the famous bill was brought into the Houfe of Commons for the naturalization of the Jews, Mr Tucker, confidering the meafure rather as a merchant or politician than as a Chriftian divine, wrote in defence of it with a degree of zeal which, to fay no more, was at leaft indecent in a man of his profeffion. As fuch it was viewed by his brethren of the clergy, and by his parifhioners; for, while the former attacked him in pamphlets, newfpapers, and magazines, the latter burnt his effigy dreffed in canonicals, together with the letters which he had written in defence of the naturalization.

In the year 1753 he publifhed an able pamphlet on the "Turkey Trade;" in which he demonftrates the evils that refult to trade in general from chartered companies. At this period Lord Clare (afterwards Earl Nugent) was returned to Parliament for Briftol; which honour he obtained chiefly through the ftrenuous exertions of Mr Tucker, whofe influence in his large and wealthy parifh was almoft decifive on fuch an occafion. In return for this favour the earl procured for him the deanery of Gloucefter, in 1758, at which time he took his degree of doctor in divinity. So great was his reputation for commercial knowledge, that Dr Thomas Hayter, afterwards Bifhop of London, who was then tutor to his prefent majefty, applied to Dr Tucker to draw up a differtation on this fubject for the perufal of his royal pupil. It was accordingly done, and gave great fatisfaction. This work, under the title of "The Elements of Commerce," was printed in quarto, but never publifhed.

Dr Warburton, who became Bifhop of Gloucefter in the year 1760, thinking very differently from Dr Tucker of the proper ftudies of a clergyman, as well as of the project for naturalizing the Jews, faid once to a perfon who was praifing the Elements of Commerce, that "his Dean's trade was religion, and religion his trade." This farcafm, though not perhaps groundlefs, was certainly too fevere; for fome of the Dean's publications evince him to have devoted part of his time at leaft to the ftudy of theology, and to have been a man of genuine benevolence.

In the year 1771, when a ftrong attempt was made to procure an abolition of fubfcription to the 39 articles, Dr Tucker came forward as an able and moderate advocate of the church of England. About this time he publifhed "Directions for travellers;" in which he lays down excellent rules, by which gentlemen who vifit foreign countries may not only improve their own minds, but turn their obfervations to the benefit of their native country.

The Dean was an attentive obferver of the American conteft. He examined the affair with a very different eye from that of a party-man, or an interefted merchant; and he difcovered, as he conceived, that both fides would be better off by an abfolute feparation. Mr Burke's language in the Houfe of Commons, in confequence of his publifhing this opinion, was harfh, if not illiberal. In his famous fpeech on the American taxation bill, April the 13th, 1774, he called the Dean of Gloucefter the advocate of the court faction, though it is well known that the court difapproved of the propofal as much as the oppofition. This attack roufed the Dean to refentment; and he publifhed a letter to Mr Burke; in which he not only vindicates the purity of his own principles, but retorts upon his adverfary in very forcible and farcaftic terms. He afterwards fupported Lord Nugent's intereft in Briftol againft that of Mr Burke, and was certainly very inftrumental in making the latter lofe his election.

When the terrors of an invafion were very prevalent in 1779, Dr Tucker circulated, in a variety of periodical publications, fome of the moft fenfible obfervations that were ever made on the fubject, in order to quiet the fears of the people. In 1781 he publifhed, what he had printed long before, "A Treatife on Civil Government," in which his principal defign is to counteract the doctrines of Locke and his followers. The book made a confiderable noife, and was very fharply attacked by feveral writers on the democratic fide of the queftion, particularly by Dr Towers and Dr Dunbar of Aberdeen. This laft gentleman acted a part which, if not difhonourable, was at leaft uncommon. The Dean had thrown off thirty copies of his work long before he publifhed it; and thefe he fent to different men of eminence, that he might avail himfelf of their animadverfions before he fhould fubmit it to the public at large. Principal Campbell of Aberdeen received one copy for this purpofe; and Dr Dunbar having

ing by him been favoured with a perusal of it, instead of sending his objections privately to the author, published severe remarks on it in a work which he had then in the press. Thus was the answer to the Dean of Gloucester's Treatise on Government published before that treatise itself; but Dr Dunbar was no match for Dr Tucker.

In the year 1782 our author closed his political career with a pamphlet intitled "*Cui Bono?*" in which he balances the profit and loss of each of the belligerent powers and recapitulates all his former positions on the subject of war and colonial possessions. His publications since that period consisted of some tracts on the commercial regulations of Ireland, on the exportation of woollens, and on the iron trade. In 1777 he published seventeen practical sermons, in one volume octavo. In the year 1778, one of his parishioners, Miss Pelloquin, a maiden lady of large fortune and most exemplary piety, bequeathed to the Dean her dwelling house in Queen-Square, Bristol, with a very handsome legacy, as a testimony of her great esteem for his worth and talents. In the year 1781 the Dean married a lady of the name of Crowe, who resided at Gloucester.

It should be recorded to his praise, that though enjoying but very moderate preferment (for to a man of no paternal estate, or other ecclesiastical dignity, the Deanery of Gloucester is no very advantageous situation), he was notwithstanding a liberal benefactor to several public institutions, and a distinguished patron of merit. The celebrated John Henderson of Pembroke-College, Oxford, was sent to the university, and supported there, at the Dean's expense, when he had no means whatever of gratifying his ardent desire for study. We shall mention another instance of generosity in this place, which reflects the greatest honour upon the Dean. About the year 1790 he thought of resigning his rectory in Bristol, and, without communicating his design to any other person, he applied to the Chancellor, in whose gift it is, for leave to quit it in favour of his curate, a most deserving man, with a large family. His Lordship was willing enough that he should give up the living, but he refused him the liberty of nominating his successor. On this the Dean resolved to hold the living himself till he could find a fit opportunity to succeed in his object. After weighing the matter more deliberately, he communicated his wish to his parishioners, and advised them to draw up a petition to the Chancellor in favour of the curate. This was accordingly done, and signed by all of them, without any exception, either on the part of the dissenters or others. The Chancellor being touched with this testimony of love between a clergyman and his people, yielded at last to the application; in consequence of which the Dean cheerfully resigned the living to a successor well qualified to tread in his steps. Since that time he resided chiefly at Gloucester, viewing his approaching dissolution with the placid mind of a Christian, conscious of having done his duty both to God and man. He died in November 1799. The following we believe to be a tolerably correct list of his works.

Theological and Controversial.—1. A Sermon, preached before the Governors of the Infirmary of Bristol, 1745. 2. Letters in behalf of the Naturalization of the Jews. 3. Apology for the Church of England, 1772. 4. Six Sermons, 12mo, 1773. 5. Letter to Dr Kippis on his Vindication of the Protestant Dissenting Ministers. 6. Two Sermons and Four Tracts. 7. View of the Difficulties of the Trinitarian, Arian, and Socinian Systems, and Seventeen Sermons, 1777.

Political and Commercial.—8. A pamphlet on the Turkey Trade. 9. A brief View of the Advantages and Disadvantages which attend a Trade with France. 10. Reflections on the Expediency of Naturalizing foreign Protestants, and a Letter to a Friend on the same Subject. 11. The Pleas and Arguments of the Mother Country and the Colonies stated. 12. A Letter to Mr Burke. 13. Quere, Whether a Connection with, or Separation from, America, would be for national Advantage? 14. Answers to Objections against the Separation from America. 15. A Treatise on Civil Government. 16. *Cui Bono?* 17. Four Letters on national Subjects. 18. Sequel to Sir William Jones on Government. 19. On the Dispute between Great Britain and Ireland. 20. Several Papers under the Signature of Cassandra, &c. on the Difficulties attendant on an Invasion. 21. A Treatise on Commerce (Mr Coxe, in his Life of Sir Robert Walpole, says that this was printed, but never published).

Miscellaneous.—22. Directions for Travellers. 23. Cautions against the Use of Spirituous Liquors. 24. A Tract against the Diversions of Cock-fighting, &c.

TUCKERTON, the port of entry for the district of Little Egg-Harbour, in the State of New-Jersey. —*Morse.*

TUCUYO, a town of New-Granada, and Terra Firma, in N. America. It stands in a valley of the same name, every where surrounded by mountains. The air is very healthy, and the soil fruitful, and a river divides the place. It is 200 miles S. of Maracaibo city. N. lat. 7 10, W. long. 68 36.—*ib.*

TUFTONBOROUGH, a town of New-Hampshire, in Strafford county, situated on the N. E. side of Lake Winipiseogee, adjoining Wolfborough, containing 109 inhabitants.—*ib.*

TUGELO *River*, in Georgia, is the main branch of Savannah river. The other great branch is Keowee, which joining with the other, 15 miles N. W. of the northern boundary of Wilke's county, form the Savannah. Some branches of the Tugelo rise in the State of Tennessee. A respectable traveller relates that in ten minutes, having walked his horse moderately, he tasted of Tugelo, Apalachicola, and Hiwassee rivers. —*ib.*

TUICHTENOONA *Creek*, in the State of New-York, is 16 miles above Schenectady. E. of the creek is a curious Indian inscription.—*ib.*

TULIPOMANIA, the very proper name given to a kind of gambling traffic in *tulip-roots*, which prevailed in Holland and the Netherlands during some part of the 17th century. It was carried on to the greatest extent in Amsterdam, Haerlem, Utrecht, Alkmaar, Leyden, Rotterdam, Hoorn, Enkhuysen, and Meedenbliek; and rose to the greatest height in the years 1634, 1635, 1636, and 1637. Munting, who, in 1696, wrote a book of 1000 pages folio on the subject, has given a few of the most extravagant prices, of which we shall present the reader with the following. For a root of that species called the *Viceroy*, the after-mentioned articles, valued as below, were agreed to be delivered.

pomania. Tulipomania.

	Florins.
2 lasts of wheat - - -	448
4 ditto rye - - -	558
4 fat oxen - - - -	480
8 fat swine - - -	240
12 fat sheep - - - -	120
2 hogsheads of wine - -	70
4 tons beer - - - -	32
2 ditto butter - - -	192
1000 pounds of cheese - - -	120
a complete bed - -	100
a suit of clothes - - -	80
a silver beaker - -	60
Sum -	2500

These tulips afterwards were sold according to the weight of the roots. Four hundred perits* of Admiral Liefken cost 4400 florins; 446 ditto of Admiral Von der Eyk, 1620 florins; 106 perits Schilder cost 1615 florins; 200 ditto Semper Augustus, 5500 florins; 410 ditto Viceroy, 3000 florins, &c. The species Semper Augustus has been often sold for 2000 florins; and it once happened that there were only two roots of it to be had, the one at Amsterdam and the other at Haerlem. For a root of this species, one agreed to give 4600 florins, together with a new carriage, two grey horses, and a complete harness. Another agreed to give twelve acres of land for a root: for those who had not ready money, promised their moveable and immoveable goods, house and lands, cattle and clothes. A man, whose name Munting once knew, but could not recollect, won by this trade more than 60,000 florins in the course of four months. It was followed not only by mercantile people, but also by the first noblemen, citizens of every description, mechanics, seamen, farmers, turf-diggers, chimney-sweeps, footmen, maid-servants, and old clothes-women, &c. At first, every one won and no one lost. Some of the poorest people gained in a few months houses, coaches, and horses, and figured away like the first characters in the land. In every town some tavern was selected which served as a change, where high and low traded in flowers, and confirmed their bargains with the most sumptuous entertainments. They formed laws for themselves, and had their notaries and clerks.

* perit is ... small ... ght less ... a ... n.

To get possession of fine flowers was by no means the real object of this trade, though many have said that it was, and though we have known some individuals in Scotland, who, led away by what they thought the fashion, have given ten guineas for a tulip root. During the time of the tulipomania, a speculator often offered and paid large sums for a root which he never received, and never wished to receive. Another sold roots which he never possessed or delivered. Oft did a nobleman purchase of a chimney-sweep tulips to the amount of 2000 florins, and sold them at the same time to a farmer; and neither the nobleman, chimney-sweep, or farmer, had roots in their possession, or wished to possess them. Before the tulip season was over, more roots were sold and purchased, bespoke, and promised to be delivered, than in all probability were to be found in the gardens of Holland; and when Semper Augustus was not to be had, which happened twice, no species perhaps was oftener purchased and sold. In the space of three years, as Munting tells us, more than ten millions were expended in this trade in only one town of Holland.

To understand this gambling traffic, it may be necessary to make the following supposition. A nobleman bespoke of a merchant a tulip root, to be delivered in six months, at the price of 1000 florins. During these six months the price of that species of tulip must have risen or fallen, or remained as it was. We shall suppose that, at the expiration of that time, the price was 1500 florins; in that case, the nobleman did not wish to have the tulip, and the merchant paid him 500 florins, which the latter lost and the former won. If the price was fallen when the six months were expired, so that a root could be purchased for 800 florins, the nobleman then paid to the merchant 200 florins, which he received as so much gain; but if the price continued the same, that is, 1000 florins, neither party gained or lost. In all these circumstances, however, no one ever thought of delivering the roots or of receiving them. Henry Munting, in 1636, sold to a merchant at Alkmaar, a tulip root for 7000 florins, to be delivered in six months; but as the price during that time had fallen, the merchant paid, according to agreement, only 10 *per cent.* "So that my father (says the son) received 700 florins for nothing; but he would much rather have delivered the root itself for 7000." The term of these contracts was often much shorter, and on that account the trade became brisker. In proportion as more gained by this traffic, more engaged in it; and those who had money to pay to one, had soon money to receive of another; as at faro, one loses upon one card, and at the same time wins on another. The tulip dealers often discounted sums also, and transferred their debts to one another; so that large sums were paid without cash, without bills, and without goods, as by the Virements at Lyons. The whole of this trade was a game at hazard, as the Mississippi trade was afterwards, and as stock-jobbing is at present. The only difference between the tulip trade and stock-jobbing is, that at the end of the contract the price in the latter is determined by the Stock Exchange; whereas in the former it was determined by that at which most bargains were made. High and low priced kinds of tulips were procured, in order that both the rich and the poor might gamble with them; and the roots were weighed by perits, that an imagined whole might be divided, and that people might not only have whole, but half and quarter lots. Whoever is surprised that such a traffic should become general, needs only to reflect upon what is done where lotteries are established, by which trades are often neglected, and even abandoned, because a speedier mode of getting fortunes is pointed out to the lower classes.

At length, however, this trade fell all of a sudden. Among such a number of contracts many were broken; many had engaged to pay more than they were able; the whole stock of the adventurers was consumed by the extravagance of the winners; new adventurers no more engaged in it; and many becoming sensible of the odious traffic in which they had been concerned, returned to their former occupations. By these means, as the value of tulips still fell, and never rose, the sellers wished to deliver the roots *in natura* to the purchasers at the prices agreed on; but as the latter had no desire for

for tulips at even such a low rate, they refused to take them or to pay for them. To end this dispute, the tulip-dealers of Alkmaar sent, in the year 1637, deputies to Amsterdam; and a resolution was passed on the 24th of February, that all contracts made prior to the last of November 1636 should be null and void; and that, in those made after that date, purchasers should be free on paying ten *per cent.* to the vender.

The more disgusted people became with this trade, the more did complaints increase to the magistrates of the different towns; but as the courts there would take no cognizance of it, the complainants applied to the States of Holland and West Friesland. These referred the business to the determination of the provincial council at the Hague; which, on the 27th of April 1637, declared that it would not deliver its opinion on this traffic until it had received more information on the subject; that in the mean time every vender should offer his tulips to the purchaser; and, in case he refused to receive them, the vender should either keep them, or sell them to another, and have recourse on the purchaser for any loss he might sustain. It was ordered also, that all contracts should remain in force till farther enquiry was made. But as no one could foresee what judgment would be given respecting the validity of each contract, the buyers were more obstinate in refusing payment than before; and venders, thinking it much safer to accommodate matters amicably, were at length satisfied with a small profit instead of exorbitant gain: and thus ended this extraordinary traffick, or rather gambling. *Beckmann's History of Inventions*, vol. i.

TULLY, one of the military townships of Onondago county, New-York, having Sempronius on the west, and Fabius on the east. It is within the jurisdiction of Pompey, and lies 29 miles S. E. of the ferry on Cayuga Lake.—*Morse.*

TULPEHOCKEN, a branch of the Schuylkill, which empties into that river at Reading. Also, the name of a town of Pennsylvania, in Lancaster county, 6 miles west of Middletown, and 65 north-west of Philadelphia. Tulpehocken creek or river, and Quitapahilla, lead within 4 miles of each other. The water communication between Schuylkill and Susquehannah must be formed over a tract of country of about 40 miles in extent, from river to river, in a straight line; but about 60 miles as the navigation must go. This tract is cut by the above 2 creeks. The bottom of the canal, through which the navigation must pass, will not here rise more than 30 feet above the level of the head waters of the above 2 creeks; nor so much as 200 feet above the level of the waters of Susquehannah or Schuylkill.—*ib.*

TUMAR, in Bengal, rent-roll or assessment.

TUMBEZ, a town in the road to Lima and Peru, in South-America, 7 leagues from Salto, a place for landing of goods consigned to this place, and in lat. 3 12 16 S. Near this town is a river of the same name, which empties into the bay of Guayaquil. It has near 70 cane houses.—*Morse.*

TUMBLING *Dam*, on Delaware river, is about 22 miles above Trenton.—*ib.*

TUMBREL, is a kind of carriage with two wheels, used either in husbandry for dung, or in artillery to carry the tools of the pioneers, &c. and sometimes likewise the money of an army.

TUNBRIDGE, a township of Vermont, Orange county, 12 miles west of Thetford. It contains 487 inhabitants.—*Morse.*

TUNGSTEN (See CHEMISTRY, n° 178, &c. in this *Suppl.*) when well fused, is, according to Guyton *alias* Morveau, of no higher specific gravity than 8.3406. This is very different from the specific gravity which has hitherto been assigned to it. The same eminent chemist concludes, from its extreme brittleness and difficulty of fusion, that it affords little promise of utility in the arts, except in metallic alloys, or by virtue of the property which its oxyd possesses, of affording fixed colours, or giving fixity to the colours of vegetables.

TUNIA, a city of New-Granada, in Terra Firma. —*Morse.*

TUNJA, a town of New-Granada and Terra Firma, in South-America. Near it are mines of gold and emeralds. The air is temperate, and the soil fruitful. It is about 30 miles south-west of Truxillo. N. lat. 4 51, W. long. 72 10.—*ib.*

TUNKHANNOCK, a township and creek in Luzerne county, Pennsylvania. The creek is a water of Susquehannah.—*ib.*

TUPINAMBAS, the name of a famous nation who inhabited Brazil on its first discovery by the Portuguese. They left their chief abode about Rio de Janeiro, and wandered up to the parts near the Amazon, where the Tapayos are now the descendants of that brave people. Their migration and history are fully described by Father Dacunha.—*ib.*

TURA *Bamba*, a spacious plain of Peru, in South-America, at the extremity of which stands the city of Quito. To this plain there is a road from Guayaquil. —*ib.*

TURBET, a township of Pennsylvania, on Susquehannah river.—*ib.*

TURIANO, a river on the north coast of South-America, 3 leagues to the east of the islands Barbarata. Near it is a salt pond which furnishes all the coast with salt, and there is harbour and road for ships to ride in. —*ib.*

TURKEY, a small town of New-Jersey, Essex county, 14 miles north-westerly of Elizabeth-Town, and 179 north-east of Philadelphia.—*ib.*

TURKEY *Foot*, in Youghiogany river, is the point of junction of the great S. Branch, Little Crossings from the south-east, and N. Branch from the northward. It is 35 miles from the mouth of the river, 22 miles S. S. W. of Berlin, in Pennsylvania, and 36 north-east of Morgantown. N. lat. 39 44.—*ib.*

TURKEY *Point*, a promontory on the north side of Lake Erie, lies opposite to Presque Isle, on the south side, about 50 miles across.—*ib.*

TURKEY *Point*, at the head of Chesapeak Bay, is a point of land formed by the waters of the bay on the north-west, and those of Elk river on the south east. It is about 15½ miles south-west of Elkton, and 44 north-east of Annapolis. Here the British army landed, in August, 1777, before they advanced to Philadelphia.—*ib.*

TURKISH *Islands*, a group of little islands, called also *Ananas*, since they are the islands of *Don Diego Luengo*, thus called by him who discovered them. They are more than 30 leagues north of Point Isabelique, on the north coast of the island of St Domingo.—*ib.*

TURKS

TURKS *Islands*, feveral fmall iflands in the Weft-Indies, about 35 leagues north-eaft of the ifland of St Domingo, and about 60 to the fouth-eaft of Crooked Ifland. The Bermudians frequently come hither and make a great quantity of falt, and the fhips which fail from St Domingo commonly pafs within fight of them. N. lat. 21 18, W. long. 71 5.—*ib.*

TURNER, a townfhip of the Diftrict of Maine, Cumberland county, on the weft bank of Androfcoggin river, which divides it from Green in Lincoln county. It was incorporated in 1786, contains 349 inhabitants. and lies 172 miles north of Bofton, and 31 fouth-weft of Hallowell.—*ib.*

TURNSOL, a dye-ftuff manufactured in Holland, the preparation of which was long kept a profound fecret. In order to miflead foreigners, the Dutch pretended that turnfol was made from rags dyed with the juice of the fun-flower (*Helianthus*), from which it obtained its name. Since the late revolution, however, in Holland, the true method employed by the Dutch for preparing this colour has been difcovered, and the procefs is as follows:—That kind of lichen called orchil (Lichen-*Rocella*. See that article in this *Suppl.*), or, when that cannot be procured, the large oak-mofs, after being dried and cleaned, is reduced to powder, and by means of a kind of oil-prefs the powder is forced through a brafs fieve, the holes of which are fmall. The fifted powder is then thrown into a trough, and mixed with an alkali called *vetas*, which is nothing elfe than the afhes of wine lees, in the proportion of half a pound of afhes to one pound of powder. This mixture is moiftened with a little human urine, for that of other animals contains lefs ammonia, by which a fermentation is produced; and the moiftnefs is ftill kept up by the addition of more urine. As foon as the mixture affumes a red colour, it is poured into another trough; is again moiftened with urine, and then ftirred round in order that the fermentation may be renewed. In the courfe of a few days it acquires a bluifh colour, and is then carefully mixed with a third part of very pure pulverifed potafh; after which the mixture is put into wooden pails, three feet in height, and about half a foot broad. When the third fermentation takes place, and the pafte has acquired a confiderably dark blue colour, it is mixed with chalk or pulverifed marble, and ftirred well round that the whole may be completely united. This laft fubftance gives the colour no higher quality, and is intended merely to add to the weight. The blue, prepared in this manner, is poured into oblong fquare iron moulds; and the cakes, when formed, are placed upon fir boards on an airy floor in order to dry, after which they are packed up for fale.

TURPENTINE, a well known fubftance extracted from the pine. Under the article Pinus (*Encycl.*), we have given an account of one procefs by which this extract is made; but the following, which is taken from the 31ft volume of the *Journal de Phyfique*, is very different, and probably better. The pine from which turpentine is extracted, is never fit for this operation till it be thirty years of age. The extraction is begun in February and continued to the end of October. Incifions are made with an hatchet, beginning at the foot of the tree on one fide, and rifing fucceffively: they are repeated once or twice a week, the fize about one finger's breadth acrofs, and three or four inches long.

During the four years in which it is continued, the incifions have rifen to about eight or nine feet. Then the incifions are begun on the other fide; and during this time the old ones fill up, and may be again opened after fome years, fo that a tree on a good foil, and well managed, may yield turpentine for a century. At the bottom of the tree, under the incifion, a hole is dug in the ground to receive the refin which flows from the tree. This refin is called *terebinthine brut*, is of a milky colour, and is that which flows during the three fummer months; it requires further purification.

The winter crop is called *barras galipot*, or white refin: it fticks to the bark of the tree, when the heat has not been ftrong enough to let it flow into the trough in the ground. It is fcraped off with iron knives.

Two methods are practifed for purifying thefe refins. That which is followed at Bayonne is to have a copper cauldron which will hold 300 lb. of materials fixed over a fire, and the flame circulating at the bottom of the copper. The turpentine is put in, melted with a gentle heat, and, when liquid, it is ftrained through a ftraw-bafket made for the purpofe, and ftretched over a barrel, which receives the ftrained turpentine. This purification gives it a golden colour, and may be performed at all times of the year.

The fecond manner, which is practifed only in the mountain of De Buch, near Bordeaux, confifts in having a large tub, feven or eight feet fquare, and pierced with fmall holes at the bottom, fet upon another tub to catch the liquor. This is expofed to the hotteft fun for the whole day, filled two-thirds with turpentine, which as it melts falls through the holes, and leaves the impurities behind. This pure turpentine is lefs golden-coloured, and is much more efteemed than the other. This procefs can only be done in the fummer.

To make *oil* of turpentine, an alembic, with a worm like what is ufed by the diftillers, is employed here. It generally contains 250 lb. of turpentine, which is boiled gently, and kept at the boiling point till no more oil paffes, when the fire is damped. This generally gives 60 lb. of oil, and the operation lafts one day.

The boiling turpentine, when it will give no more oil, is tapped off from the ftill and flows into a tub, and from thence into a mould of fand, which it fills, and is fuffered to cool for at leaft two days without difturbing it. This refidue is known under the name of *colophony*. It is of a brown colour, and very dry. It may be made clearer and nearer in colour to that of the refin, by adding hot water to it before it is tapped off the ftill, and ftill boiling and ftirring the water well with it, which is done with a befom of wet ftraw; and it is then fold for rofin, but is little efteemed, as it contains no effential oil.

TURTLE, *Ifland*, in the South Pacific Ocean, is nearly a league long, and not half fo broad. It is furrounded by a reef of coral rocks, that have no foundings without them. S. lat. 19 49, W. long. 177 57.—*Morse.*

Turtle *Creek*, in Pennfylvania, a fmall ftream which empties through the E. bank of Monongahela river, about 12 miles from the mouth of that river, at Pittfburg. At the head of this creek, General Braddock engaged a party of Indians, the 9th of July, 1755, on his way to Fort du Quefne, now Pittfburg, where he was repulfed, himfelf killed, his army put to flight, and the remains of the army brought off the field by the addrefs and courage of Colonel, afterwards General Wafhington.—*ib.*

Turtle *River*, in Georgia, empties into St Simon's Sound, and its bar has a fufficiency of water for the largeft veffel that fwims. At its mouth is the town of Brunfwick, which has a noble and capacious harbour. The town is regularly laid out, but not yet built. The lands on the banks of this river are faid to be excellent. —*ib.*

TURY, a river on the coaft of Brazil, in S. America, 40 leagues E. S. E. of the river Cayta. The ifland of St John lies juft off the river's mouth, and makes a very good harbour on the infide of it. But the paffage both in and out, is difficult, and no pilots are to be had.—*ib.*

TUSCARORA *Creek*, a fmall ftream of Pennfylvania, which empties through the S. W. bank of Juniatta river, 12 miles fouth-eaftward of Lewiftown.—*ib.*

Tuscarora *Villages*, lie a mile from each other, 4 miles from Queenftown, in Upper Canada, containing together about 40 decayed houfes. Veftiges of ancient fortifications are vifible in this neighbourhood. The Indian houfes are about 12 feet fquare; many of them are wholly covered with bark, others have the walls of logs, in the fame manner as the firft fettlers among white people built their huts, having chimnies in which they keep comfortable fires. Many of them, however, retain the ancient cuftom of having the fire in the centre of the houfe. The lands in the vicinity are of a good quality.—*ib.*

TUSCARORAS, a tribe of Indians in the ftate of New-York. They migrated from North Carolina, about the year 1712, and were adopted by the Oneidas, with whom they have fince lived, on the fuppofition that they were originally the fame tribe, from an affinity which there is in their language. They now confift of about 400 fouls, their village is between Kahnanwolohale and New-Stockbridge, on Tufcarora or Oneida Creek. They receive an annuity of about 400 dollars from the United States.—*ib.*

TUSCULANUM, a villa belonging to Cicero, near Tufculum, where he wrote his *Quæftiones Tufculanæ*, fo named from the place; thus become famous as well for the productions of genius as of nature. Formerly the villa of Sylla: now called *Grotta Ferrata*.—Another *Tufculanum* (infcription), a town of the Tranfpadana, fituated on the weft fide of the Lacus Benatus. Now faid to be called *Tofcolano*, in the territory of Brefcia, fubject to Venice. Here many monuments of antiquity are dug up.

TUSCULUM (anc. geog.) a town of Latium, to the north of Alba, fituated on an eminence, and therefore called *Supernum* (Horace, Strabo). In fight of Rome, at about the diftance of 100 ftadia, or 12 miles. Adorned with plantations and princely edifices: The fpot remarkable for the goodnefs of the foil, and its plenty of water. Built by Telegonus, who flew his father Ulyffes (Ovid, Horace); called the grandfon of Ulyffes in Silius Italicus. A municipium (Cicero); the birth-place of the elder Cato (Nepos, Cicero). Now *Frefcati*, in the Campania of Rome.

TUSKARAWI, the ancient name of a head water of Mufkingum river. It is alfo called Tufcarawas. —*Morse.*

TUTAPAN, a large town on the W. coaft of New-Mexico, in the N. Pacific Ocean. From the river Sacatulca, the high and rugged land extends N. W. 25 leagues.—*ib.*

TUTENAG, according to Sir George Staunton, is, properly fpeaking, zinc extracted from a rich ore, or calamine. The ore is powdered and mixed with charcoal-duft, and placed in earthen jars over a flow fire, by means of which the metal rifes in the form of vapour, in a common diftilling apparatus, and afterwards is condenfed in water. The calamine from which tutenag is thus extracted, contains very little iron, and no lead or arfenic, fo common in the calamine of Europe (See Calamine, *Encycl.*) Hence it is that tutenag is more beautiful than our zinc, and that the white copper of the Chinefe takes fo fine a polifh. See *White Copper*, in this *Supplement.*

TWELVE ISLES, or *Twelve Apoftles*, ifles on the S. fide of Lake Superior, and on the S. fide of the mouth of Weft Bay.—*Morse.*

TWENTY MILE *Creek*, an eaftern branch of Tombigbee river, in Georgia, which runs firft a S. by E. courfe, then turns to the S. W. Its mouth lies in about lat. 33 33 N. and long. 88 W.—*ib.*

Twenty Five Mile *Pond*, a fettlement in Lincoln county, Diftrict of Maine.—*ib.*

TWIGHTWEES, a tribe of Indians, in the N. W. Territory, inhabiting near Miami river and Fort. Warriors 200.—*ib.*

TYBEE *Ifland*, on the coaft of Georgia, lies at the mouth of Savannah river, to the fouthward of the bar. It is very pleafant, with a beautiful creek to the W. of it, where a fhip of any burden may lie fafe at anchor. A light-houfe ftands on the ifland, 80 feet high, and in lat. 32 N. and long. 81 10 W. The light-houfe is 7 miles E. S. E. ½ E. from Savannah, and 6 S. W. ¼ W. from Port Royal.—*ib.*

TYBOINE, a townfhip of Pennfylvania, in Cumberland county.—*ib.*

TYERS (Thomas), an author both in poetry and profe, the friend of Johnfon, and well known to moft of the eminent characters of the prefent time, was a ftudent of the Temple in 1753. His father intended him for the law, but the young man it feems penned a fonnet when he fhould engrofs. He was an accomplifhed, but not a profound man; and had tafte and elegance of mind, flightly tinged with gleams of genius. He wrote fome paftorals and political tracts, which probably will not furvive the partiality of his particular friends.

TYGART's *Valley*, in Pennfylvania, lies on Monongahela river.—*Morse.*

TYGER, a fmall river of S. Carolina, rifes in the Alleghany Mountains, and, taking a S. E. courfe nearly parallel to Enoree river, empties into Broad river, five miles above the Enoree.—*ib.*

TYNGSBOROUGH, a townfhip of Maffachufetts, Middlefex county, on Merrimack river, 31 miles north of Bofton.—*ib.*

TYPOGRAPHY, as the word imports, is the art of printing by types; but it is likewife ufed to fignify the multiplying of copies by any mechanical contrivance. Of the art of printing by types, and the many improvements from time to time either made or attempted in it, a pretty full account will be found in the *Encyclopædia*, under the titles Letter, Logography, and Printing; and in this *Supplement* under the word Printing.

PRINTING. Of typography, in the other and larger sense, some account may likewise be found in the *Encyclopædia* under the title *Method of Copying* WRITINGS; but to almost all these articles there is ample room for some additions here.

The *stereotype* printing of *Didot* and *Herhan*, being considered in France as a great improvement, must not be passed over wholly without notice. The term *stereotype* is derived from the Greek words στερεος and τυπος, because in this method the types are fixed and immoveable in the form, so that none of them can be pulled or displaced by the pressman. We need hardly observe, to those who are at all acquainted with the history of printing, that the project of soldering a whole form together, or of casting a solid form from an impression made by a general system of types, or page ready composed, is not new. It was realised 70 years ago by WILLIAM GED, a goldsmith in Edinburgh; for an account of whose method we refer the reader to his life in the *Encyclopædia*. Didot now follows nearly the same process as Ged. He does not indeed cast his types to a mass, but after the form is composed and carefully corrected, he cements or solders the types together so firmly that none of them is liable to be loosened by the action of the press or the adhesion of the balls. How far this method of printing is of value with regard to books which are altered and improved in every subsequent edition, may, perhaps, be questioned; but on a loose consideration of the subject, it seems as if it would, in every case, be advantageous to a bookseller to print a few copies of a work, and keep the types standing to print others as they may be wanted;—we say it would be advantageous, if it were not for the immense value in types, which would, by that means, be locked up. To form some judgment of this, it may be stated, that the works of Virgil, printed by Didot, in 18mo, form a beautiful volume of 418 pages, of 35 lines each. The character ranges line for line with that called burgeois, N° 2. in Caslon's book of specimens, the face of the letter being rather smaller; and we are told* that the price of the plates of this work is twelve hundred franks, or 50l. sterling. From this fact some judgment may be formed of the commercial question. We have casually looked at different books printed by Didot, but can say nothing of their correctness: the page is very pretty.

* De- Philoso-.

For multiplying copies of any writing, or of a book of ordinary size, Rochon, of the French National Institute, and now director of the Marine Observatory at the port of Brest, invented, about the year 1781, a machine for engraving, with great celerity and correctness, the pages of the book or manuscript on so many plates of copper. It was submitted to the examination of a committee of the Royal Academy of Sciences, whose report of its utility was given in the following words:

"This machine appears to us to unite several advantages. *1st*, Engraved editions of books may be executed, by this means, superior to those which can be made by the hand of the engraver, however skilful; and these engraved originals will be made with much more speed, and much less expense. *2d*, As this machine is portable, and of no considerable bulk, it may become very useful in armies, fleets, and public offices, for the impression of orders, instructions, &c. *3d*, It possesses the advantage which, in a variety of circumstances, is highly valuable, of being capable of being used by any man of intelligence and skill, without requiring the assistance of any professional workman. And, *lastly*, It affords the facility of waiting for the entire composition and engravings of a work before any of the copies are pulled off; the expense of plates, even for a work of considerable magnitude, being an object of little charge; and this liberty it affords to authors, may prove highly beneficial in works of which the chief merit consists in the order, method, and connection of ideas."

Rochon's machine consists of two brass wheels*, placed on the same axis above each other, and separated by a number of pillars, each two inches in length. These two wheels, with the interval which separates them, are equivalent to a single wheel about three inches thick. In order therefore to simplify the description, they are considered as a single wheel which moves freely on its axis.

* See Plate XLVI.

This wheel is perforated near its circumference with a number of square holes, which are the sheaths or sockets through which a like number of steel punches, of the same shape, are inserted, and are capable of moving up and down. They are very well fitted; and from this circumstance, as well as the thickness of the double wheel, they have no shake, or side motion, independent of the motion of the wheel itself. Every punch is urged upwards by a separate spring, in such a manner, that the wheel armed with its characters, or steel types (the lower faces of the punches being cut into the figures of the several letters), may turn freely on its axis; and if it be moved, the several punches will pass in succession beneath an upright screw, for pressure. The screw is fixed in a very firm and solid frame, attached to the supports of the machine; and by this arrangement a copperplate, disposed on the table, or bed of the apparatus, will receive the impression of all the punches in succession, as they may be brought beneath the vertical pressing screw, and subjected to its action.

But as the press is fixed, it would necessarily follow that each successive impression would, in part, destroy or mutilate the previous impressions, unless the plate itself were moveable. It therefore becomes necessary that the plate should be moveable in two directions: the first, to determine the interval between the letters and words, and form the lines; and the other motion, which is more simple, because its quantity may remain the same through the whole of a book, serves to give the interval between line and line, and to form the pages.

It will easily be conceived that it would be a tedious operation to seek, upon the circumference of the wheel, each several character, as it might be required to come beneath the press, because it is necessary to repeat this operation as many times as there are characters in a work. The author has considerably diminished the time and trouble of this operation, by fixing upon the aixs of the great wheel, which carries the punches, another small wheel, about four inches in diameter, the teeth of which act upon a rack, which carries a rule moving between two sliders. This rule, or straight line, will therefore represent the developement, or unfolding of the circumference of the wheel which causes it to move, and will shew the position at the great wheel, which carries the punches. For these two wheels being concentric, the developement of the fmall toothed wheel, of about two inches radius, will exhibit, in a fmall fpace (for example that of a foot), an accurate regifter of the relative pofitions of the punches with regard to the prefling-fcrew. To obtain this effect, nothing more is neceffary than to place a fixed index oppofite to the moveable rule, which laft is divided in the following manner:

The punch on which the firft letter of the alphabet is engraved, muft be brought under the centre of the prefling-fcrew; and a line of divifion then drawn upon the moveable rule, to which the letter itfelf muft be added to diftinguifh it. The index, already mentioned, being placed oppofite, and upon this firft divifion, will ferve to place immediately beneath the prefling-fcrew the punch or rather the character, correfponding with the divifion upon the rule, without its being afterwards neceffary to infpect the place either of the punch or the fcrew, with regard to each other. Confequently, as foon as the divifions which correfpond with all the punches inferted in the wheel are engraved upon the ftraight rule, the fixed index will immediately determine the pofition into which that wheel muft be brought, in order to place the punches under the prefling-fcrew in the order which the work may require.

This regifter, for this name diftinguifhes the rule and its index, has no other function in the machine than to guide the hand of the operator, and to fhew when the punch is very near its proper pofition beneath the prefling-fcrew. When this is the cafe, the required pofition is accurately obtained by means of a detent or catch.

The detent which he ufes for this operation is a lever with two tails, one of which is urged toward the circumference of the wheel by a fpring. To this extremity of the lever is fixed a piece of hardened fteel, of the figure of a wedge, which, by means of a fpring, is preffed towards the axis of the great wheel, but may be relieved, or drawn back, by preffure on the oppofite tail of the lever, fo as to permit the great wheel to revolve at liberty.

In the next place, it muft be explained how this detent takes hold of the wheel, fo as to retain it precifely in the fituation neceffary to caufe any one of the punches, at pleafure, to give its impreffion to the plate. For this purpofe there are a number of notches cut in the circumference of the wheel, for the purpofe of receiving the detent. Thefe notches may be about half an inch deep, wider towards the circumference than elfewhere, and it will be of advantage that this outer width fhould be as great as the circumference of the wheel can conveniently allow. By this contrivance, the wedge will not fail to prefent itfelf oppofite to one of the notches into which it will fall, and draw the wheel exactly to its due fituation, even though the index of the regifter fhould not be brought precifely to the line of divifion appropriated to any particular letter. For if this laft degree of precifion were required in working the machine, it would be very prejudicial to the requifite fpeed which, above all things, is required in its ufe. When the wedge is therefore left at liberty, it not only enters immediately into its place, and moves the wheel till its two fides apply fairly to the interior furfaces of the notch, but retains the wheel in this ftate with the neceffary degree of ftability.

The method of giving the proper figure to thefe notches is very eafy. For this purpofe it is neceffary, in the firft place, to imprefs all the characters contained in the wheel on a plate of copper or pewter. The fupport on which the plate is fixed muft be moved in a right line, after each ftroke of the punch, through fuch a fpace that the characters may be arranged one after the other without touching. Now, as the perfect linear arrangement (fuppofing every other part to be true) muft depend on the notches, it might feem fufficient to cut thefe according to the method ufed for the wheels of clock-work: but as it is very difficult to avoid fome obliquity on the face of the punch, and perhaps in the hole through which it paffes, it is in almoft every cafe neceffary to retouch the notch itfelf. The requifite degree of precifion may be eafily obtained, when, upon examining with attention the print of the characters engraved upon the plate, the inequalities fhall have been afcertained by a very fine line paffing exactly under the bafe of two fimilar letters, affumed as objects of comparifon: for the irregularity of linear pofition may, by this means, be determined with great exactnefs, and remedied to the moft extreme nicety. In this operation, the workman muft file away part of that furface of the notch which is oppofite to the direction of the motion the character requires. Great care muft be taken to file only a fmall portion at a time, in order that the inftant may be feized at which the wedge, by entering into the notch, brings the character to its due fituation.

Thefe details, refpecting the right-lined arrangement on the characters, muft not divert our attention from the very great celerity with which any letter is brought to its place under the prefs by means of the regifter and detent. This celerity is an object of fo much importance in the engraving of a great work, that every means ought to be purfued which may tend to increafe it. For this reafon it is that inftead of following the alphabetic order in the arrangement of punches on the furface of the wheel, we ought to prefer that in which the fum of the different motions to be given to the wheel, for engraving an entire work, fhall be the leaft poffible. This tedious enquiry may well be difpenfed with, by obferving the order in which printers difpofe their cafes of characters, that the letters of the moft frequent recurrence may be moft immediately under the hand of the workman.

If all the characters afforded an equal refiftance to impreffion in a plate of metal, a conftant force would never fail to drive the punches to the fame depth. But the faces of the letters are very unequal, and confequently it will be neceffary to ufe a variable force. Moft workmen ufe the hammer, and not a fcrew, as in this machine for ftamping. If the hammer had been ufed in this machine, it is evident, that if we fuppofed it to have fallen from the fame height upon every one of the punches, the force of the ftroke could be rendered variable according to the nature of the characters, by placing a capital, or head, upon each, of an height properly adjufted to receive the hammer after paffing through a greater or lefs fpace. But the heads of our punches are variable at pleafure, becaufe they are fcrewed on; and thus it is that, by experimentally adjufting the heads of all the punches, a fet of impreffions are obtained of equal depths from every one of them. When, for

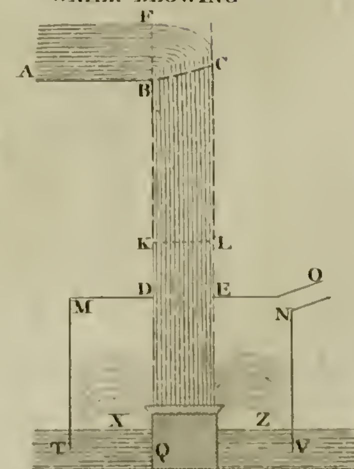
WATER BLOWING



Lawson sculp.

for example, the letter *i* is placed under the hammer, the upper part of its head is at a fmall diftance from the head of the hammer, in order that its fall, which begins always at the fame place, may ftrike this letter weakly; but when the letter M is brought under the hammer, the upper part of its head being much lefs elevated than that of the letter *i*, will receive a much ftronger blow. The impreffions of the letters M and *i* will therefore always be equally deep, if the heads of the punches be once properly fixed by experiment.

Inftead of the ftroke of a hammer, however, our author makes ufe of the preffure of a fcrew, of which the threads are fo inclined that it runs through its female focket, and would fall out merely by its own weight. This conftruction affords the double advantage of preferving the impreffions from the effects of the circular motion, and of affording a fall in the fcrew of nearly nine lines for each revolution. The head of this fcrew is folidly fixed in the centre of a brafs wheel, of which the pofition is horizontal. The diameter of this wheel muft be fufficiently large, that its motion may not be perceptibly affected by the irregularities of friction in the fcrew. This confiderable diameter is alfo requifite, becaufe the preffure of the fcrew depends, not only upon the force which is applied, but the diftance of the place of application from the centre of movement.

It is effential that this wheel fhould have very little fhake; for which reafon it is advifable that the axis of the fcrew fhould be prolonged above the wheel itfelf, that it may flide in a focket firmly fixed to the frame of the machine. In this fituation, the wheel, which is fixed on the prolongation of the fcrew, will have its plane conftantly preferved in a fituation parallel to itfelf, without any libration, notwithftanding the rife and fall of near nine lines, or three quarters of an inch, which it undergoes for each revolution on its axis.

It has been ftated, as a requifite condition, that the fcrew fhould conftantly fall from the fame fixed point, or elevation, upon the heads of every one of the punches. To accomplifh this effential purpofe, a lever is firmly fixed to the fupport of the fcrew; which lever refembles the beam of a balance, having one of its extremities armed with a claw, and the other ferving to give it motion through a fmall vertical fpace. The claw falls into a notch in the upper furface of the wheel attached to the fcrew, as foon as that wheel has rifen to the defired elevation; and that lever itfelf is fo far limited in its motion, that it cannot take hold of the wheel, excepting when it has reached that height. The wheel, therefore, remains confined and immoveable, by means of this detent, and cannot defcend until it is delivered by preffure upon the oppofite tail of the lever. In this machine, the wheel which has the preffing fcrew for its axis does not perform an entire revolution. It was with a view that there might never be any fall capable of fhaking and difturbing the machine that the author determined to ufe only two-thirds of a revolution to ftrike thofe punches, which afford the ftrongeft refiftance. The fcrew confequently falls only through fix lines upon thofe heads which are leaft elevated, and about two lines upon thofe which ftand higheft. Whence the difference between the extreme heights does not exceed four lines.

It is obvious that fo fmall a difference is not fufficient to ftrike all the characters from M to the letter *i*, when the wheel which governs the fcrew is put in motion by a conftant weight, of which the impulfe, like that of a hammer, is increafed only by the acceleration of its fall. It is evident that this requifite variation of force might be had by changing the weight; but it is equally clear, that the numberlefs and inceffant changes which the engraving of an entire work would demand, would be incompatible with that degree of fpeed which forms one of the firft requifites. He was therefore obliged to render the force of the weight, which turns the fcrew, variable, by caufing it to act upon levers of greater or lefs lengths, according to the different quantities of impulfe required by the feveral punches. For this purpofe he adopted the following conftruction: He connected by a fteel chain to the wheel, which moves the fcrew, another wheel, having its axis horizontal, fo that the two wheels refpectively command each other. They are of equal diameter, and the chain is no longer than to make an entire turn round each wheel. This fecond wheel, or leading pully, is intended to afford the requifite variations of force, which it does by means of a fnail fixed upon its axis. The fnail is acted upon by a cord paffing over its fpiral circumference, or groove, and bearing a weight which is only to be changed when a new fet of punches for characters of a different fize are put into the great wheel. The fpiral is fo formed, that when the weight defcends only through a fmall fpace, the part of the cord, which is unwound, acts at a very fhort diftance from the centre of the pulley; but when the fall is greater, the part of the fnail upon which it acts is fo far enlarged as to afford a much longer lever, and, confequently, to give a proportionally greater effect to the ftroke. This conftruction, therefore, by giving the advantage of a longer lever to a greater fall of the fcrew, affords all the power which the nature of the work, and the different fpaces of the letters demand.

The fupport on which the plate is fixed muft, as has before been remarked, move fo as to form ftrait lines. This motion, which ferves to fpace the different characters with precifion, is obtained by means of a fcrew, the axis of which remains fixed, and carries a female fcrew or nut. The nut itfelf is attached to the fupport of the metallic plate, which receives the letters, and carries it in the right lined direction without any deviation; becaufe it is confined in a groove formed between two pieces of metal. The fcrew is moved by a lever, which can turn it in one direction only, becaufe it acts by a click upon a ratchet-wheel, which is fixed to the head of the fcrew. The action of this lever always begins from a fixed ftop; but the fpace through which it moves is variable, according to the refpective breadths of the letters. This new confideration induced M. Rochon to fix upon the rule or plate of the regifter, a number of pins, correfponding with the different divifions which anfwer to each punch: thefe pins determine the diftance to which the lever can move. It therefore becomes a condition, that its pofition in the machine fhould be oppofite to the fixed index which determines the character at any time beneath the preffing-fcrew. The lever and its pin are therefore the fole agents employed to fpace the characters. If the plate were not moved by the lever, the impreffions would fall upon each other; and thus, for example, the letter *i* would be totally obliterated by the impreffion of the letter *l*.

Whenever, therefore, it is required to difpofe the letters *i* and *l* beside each other, the plate muſt be moved after ſtriking the letter *i* through a ſpace equal to the quantity of the deſired operation. Suppoſe this to be one-fourth of a line, and that the lever ſhould run through an arc of ten degrees to move the plate through this quantity; as ſoon as the pin of the letter *l* ſhall be adjuſted to the neceſſary length to enable the lever to deſcribe an arc of ten degrees, the operation of ſpacing the two letters *i* and *l* will be reduced to that of placing the laſt letter beneath the fixed index, and moving the plate till the lever ſhall be ſtopped by the pin belonging to the letter *l*. All the other letters will be equally ſpaced, if the diſpoſition of the punches in the wheel be ſuch, that the laſt ſtroke of any letter ſhall confound itſelf with any letter of a ſingle ſtroke, ſuppoſing them to be impreſſed one after the other, without moving the lever between ſtroke and ſtroke. This arrangement deſerves to be very ſeriouſly attended to, becauſe the proceſs could not be performed without it.

Many well-informed perſons are of opinion, that the perfect equality which this machine for engraving affords in the formation of letters and ſigns the moſt difficult to be imitated, may afford a means of remedying the dangers of forgery. It is certain that the performance exhibits a ſimple and ſtriking character of preciſion, which is ſuch, that the leaſt experienced eyes might flatter themſelves, in certain caſes, to diſtinguiſh counterfeits from originals. Lavoiſier, whom the friends of ſcience and the arts will not ceaſe to regret, made ſome experiments of this kind for the *caiſſe de'ſcompte*, which were attended with perfect ſucceſs. Artiſts appointed for that purpoſe endeavoured in vain to imitate a vignette, formed by the ſucceſſive and equal motion of a character of ornament.

TYRINGHAM, a townſhip of Maſſachuſetts, Berkſhire county. It contains 1397 inhabitants, lies 14 miles from the ſhire town, and 140 weſt of Boſton.—*Morse*.

TYRONE, two townſhips of Pennſylvania; the one in York county, the other in that of Cumberland.—*ib.*

TYRREL, a maritime county of Edenton diſtrict, N. Carolina; bounded N. by Roanoke river and Albemarle Sound, and ſouth by Beaufort. It is generally a low, flat, and ſwampy country, and contains 4744 inhabitants, including 1176 ſlaves.—*ib.*

TYRTÆUS, an Athenian general and muſician, is celebrated by all antiquity for the compoſition of military ſongs and airs, as well as the performance of them. He was called to the aſſiſtance of the Lacedæmonians in the ſecond war with the Meſſenians, about 685 B. C.; and a memorable victory which they obtained over that people is attributed by the ancient ſcholiaſts upon Horace to the animating ſound of a new military flute or clarion, invented and played upon by Tyrtæus. Plutarch tells us that they gave him the freedom of their city; and that his military airs were conſtantly ſung and played in the Spartan army to the laſt hour of the republic. And Lycurgus the orator, in his oration againſt Leocrates, ſays, "The Spartans made a law, that whenever they were in arms, and going out upon any military expedition, they ſhould all be firſt ſummoned to the king's tent to hear the ſongs of Tyrtæus;" thinking it the beſt means of ſending them forth in a diſpoſition to die with pleaſure for their country. Fragments of his poetry, in elegiac verſe, are preſerved in Stobæus, Lycurgus Orat. in Fulvius Urſinus, at the end of Poems by illuſtrious women: and in the Oxford edition of *Eleg. & Lyric. Frag. & Scholia.* printed 1759. Εα Συζομινα, &c.

TYTLER (William, Eſq;), ſo well known in the literary world as one of the ableſt, and certainly the moſt gentlemanly, of the defenders of the fame of Mary Queen of Scots, was born at Edinburgh, October 12, 1711. He was the ſon of Mr Alexander Tytler, writer (or attorney) in Edinburgh, by Jane, daughter of Mr William Leſlie, merchant in Aberdeen, and granddaughter of Sir Patrick Leſlie of Idan, provoſt of that city. He received his education at the grammar ſchool (or, as it is there called, the High School) and the univerſity of his native city, and diſtinguiſhed himſelf by an early proficiency in thoſe claſſical ſtudies, which, to the lateſt period of his life, were the occupation of his leiſure hours, and a principal ſource of his mental enjoyments.

In the year 1731, he attended the academical lectures of Mr Alexander Bayne, Profeſſor of municipal law in the univerſity of Edinburgh, a gentleman diſtinguiſhed alike for his profeſſional knowledge, his literary accompliſhments, and the elegance of his taſte. The Profeſſor found in his pupil a congenial ſpirit; and their connection, notwithſtanding the diſparity of their years, was ſoon ripened into all the intimacy of the ſtricteſt friendſhip. So ſtrong indeed became at length that tie of affection, that the worthy Profeſſor, in his latter years, not only made him the companion of his ſtudies, but when at length the victim of a lingering diſeaſe, choſe him as the comforter of thoſe many painful and melancholy hours which preceded his death.

At the age of 31, Mr Tytler was admitted into the Society of Writers to his Majeſty's Signet, and continued the practice of that profeſſion with very good ſucceſs, and with equal reſpect from his clients and the public, till his death, which happened on the 12th of September 1792. He married, in September 1745, Anne Craig, daughter of Mr James Craig of Dalnair, writer to the ſignet, by whom he has left two ſons, Alexander Fraſer Tytler, his Majeſty's Judge advocate for Scotland, and Profeſſor of civil hiſtory in the univerſity of Edinburgh; and Patrick Tytler, Lieutenant-colonel of a regiment of fencible infantry, and Fort-major of the caſtle of Stirling; together with one daughter, Miſs Chriſtina Tytler. His wife died about nine years before him; and, previouſly to that period, he had loſt a ſon and a daughter, both grown to maturity.

The moſt remarkable feature of Mr Tytler's character was an ardour and activity of mind, prompted always by a ſtrong ſenſe of rectitude and honour. He felt with equal warmth the love of virtue and the hatred of vice; he was not apt to diſguiſe either feeling, nor to compromiſe, as ſome men more complying with the world might have done, with the faſhion of the time, or the diſpoſition of thoſe around him. He ſeldom waved an argument on any topic of hiſtory, of politics, or literature; he never retreated from one on any ſubject that touched thoſe more important points on which he had formed a decided opinion. Decided opinions he always formed on ſubjects of importance; for on ſuch ſubjects he formed no opinions raſhly; and what he firmly believed he avowed with confidence, and ſometimes with warmth.

Nor

Tytler.

Nor was it in opinion or argument only that this warmth and ardour of mind were confpicuous. They prompted him equally in action and conduct. His affection to his family, his attachment to his friends and companions, his compaffion for the unfortunate, were alike warm and active. He was in fentiment alfo what Johnfon (who felt it ftrongly in himfelf, and mentions it as the encomium of one of his friends) calls a *good hater*; but his hatred or refentment went no further than opinion or words, his better affections only rofe into action. In his opinions, or in his expreffion of them, there was fometimes a vehemence, an appearance of acrimony, which his friends might regret, and which ftrangers might cenfure; but he had no afperity in his mind to influence his actual conduct in life. He indulged oppofition, not enmity; and the world was juft to him in return. He had opponents; but two of his biographers, who knew him well, as well as the people with whom he moft affociated, declare their belief that he had not a fingle enemy. His contefts were on opinions, not on things; his difputes were hiftorical and literary. In converfation, he carried on thefe with uncommon intereft and vivacity; and the fame kind of impulfe which prompted his converfation (as is juftly obferved by an author, who publifhed fome notices of his life and character in the periodical work intitled *The Bee*) induced him to become an author. He wrote not from vanity or vain-glory, which Rouffeau holds to be the only inducement to writing; he wrote to open his mind upon paper; to fpeak to the public thofe opinions which he had often fpoken in private; opinions on the truth of which he had firmly made up his own conviction, and was fometimes furprifed when he could not convince others: it was fair to try, if, by a fuller expofition of his arguments, he could convince the world.

With this view, he publifhed, in 1759, his "Inquiry, hiftorical and critical, into the Evidence againft *Mary Queen of Scots*, and an Examination of the Hiftories of Dr Robertfon and Mr Hume with refpect to that Evidence;" in which he warmly efpoufed the caufe of that unfortunate Princefs, attacked with feverity the conduct of her enemies, and expofed the fallacy, in many parts the fabrication, of thofe proofs on which the charges againft her had been founded.

This was a caufe worthy of an advocate who loved truth better than popular applaufe; and Mr Tytler evinced himfelf to be fuch an advocate. The problem of Mary's guilt or innocence, if confidered merely as a detached hiftorical fact, would appear an object which, at this diftance of time, feems hardly to merit that laborious and earneft inveftigation to which it has given rife; though, even in this point of view, the mind is naturally ftimulated to fearch out the truth of a dark myfterious event, difgraceful to human nature; and our feelings of juftice and moral rectitude are interefted to fix the guilt upon its true authors. But when we confider that this queftion involves a difcuffion of the politics of both England and Scotland during one of the moft interefting periods of their hiftory, and touches the characters, not only of the two fovereigns, but of their minifters and ftatefmen, it muft then be regarded in the light of a moft important hiftorical inquiry, without which our knowledge of the hiftory of our own country muft be obfcure, confufed, and unfatisfactory. In addition to thefe motives of inquiry, this queftion has exercifed fome of the ableft heads both of earlier and of latter times; and it is no mean pleafure to engage in a conteft of genius and of talents, and to try our ftrength in the decifion of a controverfy which has been maintained on both fides with confummate ability.

As we have elfewhere (fee Mary, *Encycl.*) given an abftract of the arguments on both fides of this difputed queftion, it would be altogether improper to repeat them here; but juftice to the fubject of this memoir requires us to fay, that by his manner of difcuffing it he acquired high reputation in the republic of letters. Before the appearance of the Inquiry, fays an ingenious writer, it was the fafhion for literary difputants to attack each other like mifcreants and banditti. The *perfon* was never feparated from the *caufe*; and whatever attached the *one*, was confidered as equally affecting the *other*; fo that fcurrility and abufe bloated the pages even of a Bentley and a Ruddiman. The Hiftorical Inquiry was free from every thing of that fort: and though the higheft name produced not a mitigation of the force of any argument, the meaneft never fuffered the fmalleft abufe. He confidered it as being greatly beneath the dignity of a man contending for truth, to overftretch even an argument in the fmalleft degree, far more to pervert a fact to anfwer his purpofe on any occafion. In the courfe of his argument, he had too often occafion to fhew that this had been done by others; but he difdained to imitate them. His reafoning was forcible and elegant; impartially fevere, but always polite, and becoming the gentleman and the fcholar.

When this book appeared, it was univerfally read in Britain, and very well tranflated into French, under the title of "Recherches Hiftoriques et Critiques fur les Principales Preuves del'Accufation intentée contre Marie Reine d'Ecoffe." The intereft it excited among literary men may be judged of from the character of thofe by whom it was reviewed on its publication, in the periodical works of the time. Dr Douglas, now bifhop of Salifbury, Dr Samuel Johnfon, Dr John Campbell, and Dr Smollet—all wrote reviews of Mr Tytler's book, containing very particular accounts of its merits, and elaborate analyfes of the chain of its arguments. As an argument on evidence, no fuffrage could perhaps be more decifive of its merit than that of one of the greateft lawyers, and indeed one of the ableft men that ever fat on the woolfack of England, the late Lord Chancellor Hardwicke, who declared Mr Tytler's Inquiry to be the beft concatenation of circumftantiate proofs brought to bear upon one point that he had ever perufed. What effect that body of evidence, or the arguments deduced from it, ought to have upon the minds of thofe to whom the fubject may become matter of inveftigation, we do not prefume to determine. The opinion of the late Dr Henry, author of the Hiftory of Great Britain on a New Plan, may perhaps be thought neither partial nor confident. He fays, in a letter to Mr Tytler, publifhed in the firft volume of Tranfactions of the Antiquarian Society of Scotland, That he would be a bold man who fhould now publifh an hiftory of Queen Mary in the fame ftrain with the two hiftorians (Mr Hume and Dr Robertfon), whofe opinions on the fubject the Inquiry had examined and controverted.

The moft exceptionable part of Mary's conduct, which, though it may admit of an apology, cannot be vindicated, is her marriage to Bothwell; and for that marriage-

marriage Mr Tytler made an apology, founded on facts, which he would be a daring or very bigotted man who would attempt to controvert. See the article already referred to.

Besides the *Historical Inquiry*, and the *Dissertation on the Marriage of Queen Mary with the Earl of Bothwell*, our author published several other works on historical and literary subjects; of which the first was, the *Poetical remains of James I. King of Scotland*, consisting of *the King's Queir*, in six cantos, and *Christ's Kirk on the Green*; to which is prefixed a dissertation on the Life and Writings of King James, in one volume 8vo, printed at Edinburgh in 1783. This dissertation forms a valuable morsel of the literary history of Europe; for James ranked still higher in the literary world as a *poet*, than in the political world as a *prince* (A). Great justice is done to his memory in both respects in this dissertation: and the two morsels of poetry here rescued from oblivion will be esteemed by men of taste as long as the language in which they are written can be understood.

2. "A Dissertation on Scottish Music," first subjoined to Arnot's history of Edinburgh. The simple melodies of Scotland have been long the delight of the natives, many of which, to them, convey an idea of pathos that can be equalled by none other; and are much admired by every stranger of musical talents who has visited this country. They have a powerful effect, indeed, when properly introduced, as a relief, into a musical composition of complicated harmony. These are of two kinds, pathetic and humorous. Those who wish to receive information concerning this curious subject, will derive much satisfaction from the perusal of this dissertation. There is yet another kind of music peculiar to the Highlands of Scotland, of a more wild, irregular, and animating strain, which is but slightly treated here, and requires to be still more fully elucidated.

3. "Observations on the Vision, a poem," first published in Ramsay's Evergreen, now also printed in the Transactions of the Society of Antiquaries of Scotland. This may be considered as a part of the literary history of Scotland.

4. "On the Fashionable Amusements in Edinburgh during the last century," *ibid.* It is unnecessary to dwell on the light that such dissertations as these, when judiciously executed, throw upon the history of civil society and the progress of manners. Mr Tytler was likewise the author of N° 16. of the Lounger, a weekly paper, published at Edinburgh in the year 1786. His subject is the Defects of Modern Female Education in teaching the Duties of a Wife; and he treats that subject like a master.

On all Mr Tytler's compositions the character of the *man* is strongly impressed, which never, as in some other instances, is in the smallest degree contradicted by, or at variance with, the character of the *author*. He wrote what he felt, on subjects which he felt, on subjects relating to his native country, to the arts which he loved, to the times which he revered. His heart, indeed, was in every thing which he wrote, or said, or did. He had, as his family and friends could warmly attest, all the kindness of benevolence: he had its anger too; for benevolence is often the parent of anger. There was nothing neutral or indifferent about Mr Tytler. In philosophy and in history, he could not bear the coldness, or what some might call the temperance of scepticism; and what he firmly believed, it was his disposition keenly to urge.

His mind was strongly impressed by sentiments of religion. His piety was fervent and habitual. He believed in the doctrine of a particular Providence, superintending all the actions of individuals as well as the great operations of Nature: he had a constant impression of the power, the wisdom, and the benevolence of the Supreme Being; and he embraced, with thorough conviction, the truths of Christianity.

His reading was various and extensive. There was scarcely a subject of literature or taste, and few even of science, that had not at times engaged his attention. In history he was deeply versed; and what he had read his strong retentive memory enabled him easily to recal. Ancient as well as modern story was familiar to him; and, in particular, the British history, which he had read with the most minute and critical attention. Of this, besides what he has given to the public, a great number of notes, which he left in MS. touching many controverted points in English and Scottish history, afford the most ample proof.

In music as a science he was uncommonly skilled. It was his favourite amusement; and with that natural partiality which all entertain for their favourite objects, he was apt to assign to it a degree of moral importance which some might deem a little whimsical. He has often been heard to say, that he never knew a good taste in music associated with a malevolent heart: And being asked, What prescription he would recommend for attaining an old age as healthful and happy as his own? "My prescription (said he) is simple—short but cheerful meals, music, and a good conscience."

In domestic life, Mr Tytler's character was particularly amiable and praise-worthy. He was one of the kindest husbands and most affectionate fathers. At the beginning of this account, we mentioned his having lost, at an advanced period of life, an excellent wife, and a son and a daughter both grown to maturity, who merited and possessed his warmest affections. The temper of mind with which he bore these losses, he has himself expressed in a MS. note, written not long before his death; with which, as it conveys a sentiment equally important in the consideration of this life, and in the contemplation of that which is to come, we shall conclude the present memoir: "The lenient hand of time (says he, after mentioning the death of his wife and children), the lenient hand of time, the affectionate care of my remaining children, and the duty which calls on my exertions for them, have by degrees restored me to myself. The memory of those dear objects gone before me, and the soothing hope that we shall soon meet again, is now the source of extreme pleasure to me. In my retired walks in the country I am never alone; those dear shades are my constant companions! Thus what I looked upon as a bitter calamity, is now become to me the chief pleasure in life."

U, V.

(A) There is a beautiful historical picture of this prince playing on the harp, with his queen and a circle of his courtiers listening to the music, by Graham, in London; one of the most eminent artists of the age.

U, V.

Vaccas, ‖ Valgus.

VACCAS, *Cayo*, one of the Tortugas, or Florida Keys, to the eaftward of Bahia Honda; the diftance between them is 4 leagues, and the coaft in its direction turns to the northward. On the S. fide of Cayo Vaccas, about 8 miles from the W. end, there are wells of frefh water. A thick range of ifles go by this name. Bahia Honda is in lat. 24 35 N.—*Morse.*

VACCA, called alfo the *Cow's*, or *Neat's Tongue*, a low point on the W. coaft of Chili, in S. America, which bounds the bay of Tonguey to the weftward. —*ib.*

VACHE, or *Cows Ifland*, lies on the fouth coaft of the fouthern peninfula of the ifland of St Domingo, and is about 4½ leagues long, and in the broadeft part a league and a half from N. to S. The fouth point is 3 leagues E. of Point Abacou; and in lat. 18 4 N. and long. from Paris 76 2 W. It has a very good foil, with 2 or 3 tolerable ports, and lies very conveniently for trade with the Spanifh colonies on the continent, and with Cayenne. The feamen call this Afh Ifland, a corruption from Vafh, as it is pronounced.—*ib.*

VACH ET LE TORREAU, or *Cow and Bull Rocks*, on the fouth coaft of Newfoundland ifland, are about a mile S.E. of Cape St Mary, which is the point between the deep bay of Placentia on the W. and St Mary's Bay on the eaft. They are fair above water, but there are others near them which lurk under water.—*ib.*

VACUUM Boyleanum, is the approach to a real vacuum, to which we can arrive by means of the air-pump.

Torricellian Vacuum, is the moft complete vacuum which we can make by means of the torricellian tube. See Barometer, and Pneumatics, *Encycl.*

VADE-mecum, the title given to fuch books as men of particular profeffions, having frequent occafion to confult, may eafily carry about with them. Thus a fmall volume, publifhed in the beginning of the 18th century, giving an account of the ancient and prefent church of England, and of the duties, rights, privileges, and hardfhips of the clergy, is known by the title of *the Clergyman's Vade-mecum.*

VAE'S *Ifland, Anthony*, a fmall ifland on the E. coaft of Brazil, in S. America. It lies to the fouthward of the fandy Receif, and oppofite to it, which is joined to the continent by a bridge.—*Morse.*

VAKEEL, a minifter, agent, or ambaffador.

VALADOLID or *Valladolid*, called by the Indians *Comayagua*, is the chief city of the province of Honduras, in New Spain. It is the feat of the Governor, and is a bifhop's fee fuffragant of Mexico, fince the year 1558. It is feated on a plain, 30 miles W. of the Gulf of Honduras, 170 S. W. of Truxillo, and 65 S. E. of Merida. N. lat. 14 10, W. long. 51 21.—*Morse.*

VALENCIA, a town in the province of Caracas, on Terra Firma, South-America, about 80 miles N. of Baraquicimeto, and 250 W. of Cumana. N. lat. 10, W. long. 67.—*ib.*

VALGUS, *Bow* or *Bandy Legged*. Some children are bow-legged from their birth; others become fo from fetting them on their feet too early. The tibia of fome is crooked; the knees of others are diftorted; from a fault in the ankle, the feet of fome are turned inwards, thefe are called *vari;* and in others they turn outwards, thefe are called *valgi.* The beft method of preventing thefe diforders in weakly children, is to exercife them duly, but not violently; by dancing or toffing them about in one's arms, and not fetting them much on their feet, at leaft not without properly fupporting them: if the diforder attends at the birth, or increafes after it is begun, apply emollients, then apply boots of ftrong leather, wood, &c. as required to difpofe the crooked legs gradually to a proper form: or other inftruments may be ufed inftead of boots, which, when not too coftly, are ufually to be preferred. Slighter inftances of the diforders yield to careful nurfing without inftruments.

Valley, ‖ Vandá.

VALLEY *Forge*, a place on Schuylkill river, 15 miles from Philadelphia. Here General Wafhington remained with his army, in huts, during the winter of 1777, after the Britifh had taken poffeffion of that city. —*Morse.*

VALPARAISO, a large and populous town of Chili, in South-America, having a harbour forming the port of St Jago, in lat. 33 2 36, S. and long. 77 29, W. It is 390 miles E. of the ifland of Juan Fernandes. It carries on a confiderable trade with the port of Callao.—*ib.*

VANCOUVER'S *Fort*, in Kentucky, ftands at the junction of the two branches of Big Sandy river, 20 miles N. of Harmar's ftation.—*ib.*

VANDA', the Indian name of a plant of the genus Epidendrum; which fee, *Encycl.* The *vandá* is thus defcribed by Sir William Jones.

" Cal. *Spathes* minute, ftraggling. Cor. *Petals* five, diverging, oval-oblong, obtufe, wavy; the two loweft larger; the three higheft equal, bent towards the nectary. *Nectary* central, rigid: *Mouth* gaping, oblique: *Upper lip* fhorter, three-parted, with a polifhed honey-cup; *under lip* concave in the middle, keeled above, with two fmaller cavities below, two proceffes at the *bafe*, incurved, hollow, oval pointed, converging, honey-bearing. Stam. *Filaments* very fhort. *Anthers* round, flattifh, margined, covered with a lid, eafily deciduous from the *upper lip* of the nectary. Pist. *Germ.* beneath long, ribbed, contorted with curves of oppofite flexure. *Style* very fhort, adhering to the *upper lip.* *Stigma* fimple. Per. *Capfule* oblong-conic, wreathed, fix-keeled, each with two fmaller keels, three-celled, crowned with the dry corol. Seeds innumerable, like fine duft affixed to the *receptacle* with extremely fine hairs, which become thick wool. *Scapes* incurved, folitary, from the cavity of the leaf, at moft feven-flowered; pedicles alternate. *Petals* milk-white externally, tranfparent; brown within, yellow-fpotted. *Upper lip* of the nectary fnow-white; *under lip* rich purple, or light crimfon, ftriated at the bafe, with a bright yellow gland, as it feems, on each procefs. The flowers gratefully fragrant, and exquifitely beautiful, looking as if compofed of fhells, or made of enamel; crifp elaftic, vifcid internally. *Leaves* fheath-

ing,

ing, oppofite, equally curved, rather flefhy, fword-form, retufe in two ways at the fummit, with one acute point. *Roots* fibrous, fmooth, flexible; fhooting even from the top of the leaves."

This lovely plant attaches itfelf chiefly to the higheft *Amras* and *Bilvas* (the *Mangifera* and *Crataeva* of Lin.); but it is an air-plant, and lives (fays the Prefident) in a pot *without earth or water:* its leaves are excavated upwards, to catch and retain dew.

VANDALIA, a duchy of Farther Pomerania, fubject to the king of Pruffia. Stolpen is the capital.

VANDALIA, a country in Germany, in the circle of Lower Saxony and duchy of Mecklenburg. It lies between the bifhopric and duchy of Schwerin, the lordfhips of Stocrock and Stargard, Pomerania, and the marquifate of Brandenburg; and is 75 miles in length and 7 in breadth. It contains feveral fmall lakes, and the principal town is Guftrow.

VANDERMONDE, member of the National Inftitute of Sciences and Arts, was born at Paris in the year 1735. He devoted his youth to felf-inftruction; and even at the age of thirty was far enough from fufpecting that he was deftined to inftruct others in his turn. Chance brought him near to the celebrated Fontaine. That fexagenary geometrician eafily divined the progrefs which Vandermonde would one day make in the mathematics; in him he anticipated, as it were, a fucceffor to himfelf; he patronifed and careffed him, let him into the fecret of his refearches, calculations, inventions, of that lively enjoyment which profound fpeculation gives to an elevated attentive mind; and which, blended with the fweets of tranquillity, the charms of retreat, and the confcioufnefs of fuccefs, becomes often a fort of paffion, as felicitous as durable. All that time Fontaine, whofe attention was again directed to the refearches which he had added to thofe of Jean Bernoulli, relative to the then famous queftion *of the toutocrenes*, had the glory to be vanquifhed only by D'Alembert and La Grange. Vandermonde, a witnefs to this combat, neceffarily illuftrious, animated by the honour which he faw annexed to that glorious defeat, enchanted with the fight of Fontaine, as happy, in fpite of his age, from his love of geometry, as a youth of twenty could be with a fentiment lefs tranquil, thought he fhould infure his happinefs for ever, by yielding to a paffion which the ice of age could not extinguifh; in a word, he devoted himfelf to geometry.

His labours, however, were for fome time fecret; and perhaps the public would never have enjoyed the benefit of any of his works, if another geometrician (whofe name, fays Lacepede, cannot be pronounced, in this place, without a mixture of intereft and regret) had not infpired him with a confcioufnefs of his own ftrength, and courage to difplay it. Fontaine had already devoted him to geometry; Dufejour exhorted him to penetrate even into its fanctuary. In brief, he prefented himfelf to the Academy of Sciences, into which he was admitted in 1771; and in that very year juftified the fuffrages of his affociates, by a paper which he publifhed relative to the refolution of equations.

From the 16th century the method of refolving equations of the four firft degrees has been known, and fince that time the general theory of equations has received great improvements. In fpite, however, of the recent labours of many great geometricians, the folutions of equations of the fifth degree had in vain been attempted. Vandermonde wifhed to confolidate his labours with thofe of other illuftrious analyfts; and he propofed a new theory of equations, in which he feems to have made it particularly his bufinefs to fimplify the methods of calculation, and to contract the length of the *formulae*, which he confidered as one of the greateft difficulties of the fubject.

This work was quickly followed by another on the problems called by geometricians *problems of fituation*. It feems to have been the deftiny of Vandermonde, as well as of Fontaine, who firft initiated him into the myfteries of mathematical fcience, to labour frequently upon fubjects already handled by the greateft mafter. In his firft memoir he had ftarted, fo to fpeak, in competition with La Grange and Euler; in his fecond, with Euler and Leibnitz. This laft was of opinion that the analyfis made ufe of in his time, by the geometricians, was not applicable to all queftions in the phyfical fciences; and that a new geometry fhould be invented, to calculate the relations of pofitions of different bodies, in fpace: this he called *geometry of fituation**. Excepting, however, one application, made by Leibnitz himfelf, to the game of *folitaire*, and which, under the appearance of an object of curiofity, fcarcely worthy the fublimity and ufefulnefs of geometry, is an example for folving the moft elevated and important queftions, Euler was almoft the only one who had practifed this geometry of fituation. He had reforted to it for the folution of a problem called the *cavalier*, which alfo appeared very familiar at firft fight, and was alfo pregnant with ufeful and important applications. This problem, with the vulgar, confifted merely in running through all the cafes of the chefs-board with the *knight* of the game of chefs; to the profound geometrician, however, it was a precedent for tracing the route which every body muft follow, whofe courfe is fubmitted to a known law, by conforming to certain required conditions, through all the points difpofed over a fpace in a prefcribed order. Vandermonde was chiefly anxious to find in this fpecies of analyfis a fimple notation, likely to facilitate the making of calculations; and he gave an example of this, in a fhort and eafy folution of the fame problem of the cavalier, which Euler had rendered famous.

* See Position, Suppl.

His tafte for the high conceptions of the fpeculative fciences, as blended with that which the *amor patriae* naturally infpires for objects immediately ufeful to fociety, had led him to turn his thoughts towards perfecting the arts converfant in weaving, by indicating a manner of noting the points through which are to pafs the threads intended to form the lines which terminate the furface of different regular bodies: accordingly a great part of the above memoir is taken up with this fubject.

In the year following (1772) he printed a third memoir; in which he traced out a new path for geometers, difcovering, by learned analytical refearches, *irrational* quantities of a new fpecies, fhewing the fequels of which thefe *irrationals* are the terms or the fum, and pointing out a direct and general method of making in them all the poffible reductions.

In the fame year appeared his work on the Elimination of unknown Quantities in Algebra. This elimination is the art of bringing back thofe equations which include many unknown quantities, to equations which only der- nde, ‖ enius. only contain one. The perfection of refearches in this art would confift in obtaining a general and particular *formula* of elimination in a form the moft concife and convenient, in which the number of equations and their degrees fhould be defigned by indeterminate letters. Vandermonde, while he confidered the geometers as very diftant from this point, had fome glimpfe of a poffibility of reaching it, and propofed fome new methods of approaching nearer it.

In 1778, he prefented in one of the public fittings of the Academy, a new fyftem of harmony, which he detailed more fully in another public fitting of 1780. In this fyftem, Vandermonde reduces the modes of proceeding adopted until his time, to two principal rules, which thus become eftablifhed on effects admitted by all muficians. Thefe two general rules, one on the fucceffion of according founds, the other on the arrangement of the parts, depend themfelves on a law more elevated, which, according to Vandermonde, ought to rule the whole fcience of harmony.

By the publication of this work, he fatisfactorily attained the end he had propofed to himfelf, and obtained the fuffrages of three great men, reprefentatives, fo to fpeak, of the three great fchools of Germany, France, and Italy; Gluck, Philidor, and Piccini.

With thefe labours, intermingled with frequent refearches on the mechanic arts, as well as on objects of political economy, the attention of Vandermonde was taken up; when, July 14, 1789, the voice of liberty refounded over the whole furface of France, and fuddenly all the thoughts, as well as all the affections, of Vandermonde, were engaged on the fide of what he called liberty.

He became fo furious a democrate, fo outrageous an enemy to every thing eftablifhed, that he concurred in the abolition of the Royal Academy, of which he had been fo ambitious of becoming a member, and affociated himfelf clofely with Robefpierre, Marat, and the reft of that atrocious gang of villains, who covered France with ruins, with fcaffolds, and with blood. This part of Vandermonde's hiftory is fuppreffed by his eulogift Lacepede, becaufe, forfooth, difcuffions on *political opinions* ought not, in his opinion, to be admitted into the fanctuary of the fciences.

In that fanctuary he did not long remain. Soon after his atrocities, he was attacked by a diforder in his lungs, which almoft taking away his breath, manifefted itfelf by alarming fymptoms, and conducted him by rapid fteps to the tomb. He died in the end of the year 1795; a ftriking inftance of the wayward violence of the human mind, which even the love of fcience could not keep at a diftance from tumult and uproar.

VAN DYKES, *Joft* and *Little*, two of the fmaller Virgin Iflands, fituated to the N. W. of Tortola. N. lat. 18 25, W. long. 63 15.—*Morse*.

VANNSTOWN, in the country of the Cherokees, lies on a branch of Alabama river.—*ib*.

VARENIUS (Bernard), a learned Dutch geographer and phyfician of the 17th century, who was author of the beft mathematical treatife on geography intitled *Geographia Univerfalis, in qua affectiones generalis Telluris explicantur*. This excellent work has been tranflated into all languages, and was honoured by an edition, with improvements, by Sir Ifaac Newton, for the ufe of his academical ftudents at Cambridge.

Variable, ‖ Variolæ Vaccinæ.

VARIABLE, in geometry and analytics, is a term applied by mathematicians to fuch quantities as are confidered in a variable or changeable ftate, either increafing or decreafing. Thus the abfciffes and ordinates of an ellipfis, or other curve line, are variable quantities; becaufe thefe vary or change their magnitude together, the one at the fame time with the other. But fome quantities may be variable by themfelves alone, or while thofe connected with them are conftant: as the abfciffes of a parallelogram, whofe ordinates may be confidered as all equal, and therefore conftant; alfo the diameter of a circle, and the parameter of a conic fection, are *conftant*, while their abfciffes are *variable*. See Fluxions, *Encycl*.

VARIATION of Curvature, in geometry, is ufed for that inequality or change which takes place in the curvature of all curves except the circle, by which their curvature is more or lefs in different parts of them; and this variation conftitutes the quality of the curvature of any line.

1 Variolæ Vaccinæ long known in Gloucefterfhire.

VARIOLÆ Vaccinæ, or *Cow pox*, is the name commonly, though, as fome people think, improperly, given to a very fingular difeafe, which, for two or three years paft, has occupied a great fhare of the attention of medical men. It has been many years prevalent in fome of the great dairy counties in England, particularly Gloucefterfhire; and it has been long underftood by the farmers and others in thefe counties, that it for ever exempts all perfons who have been infected with it from the contagion of fmall-pox.

It is very furprifing that, though they knew this fact, and although no perfon had ever been known to die of the cow-pox, they never thought of having recourfe to a voluntary infection of this kind, in order to free themfelves and their families from the poffibility of being infected with the variolous poifon, which fo often proves mortal. In one cafe, indeed, communicated to Dr Pearfon by Mr Downe of Bridport, the experiment was long ago tried by a farmer upon his own perfon, and with complete fuccefs: But this only makes it the more wonderful that his example fhould not have been followed.

2 And in the duchy of Holftein.

In the town of Kiel, however, in the duchy of Holftein, where the difeafe is faid to be well known, as frequently affecting cows, we are told that children are fometimes inoculated with cow-pox *(Die Finnen)*, with a view to preferve their beauty; but that the people in the country do not like this inoculation, becaufe they pretend that it leaves behind it feveral diforders.

3 Vaccine inoculation introduced by Dr Jenner.

With thefe exceptions Dr Jenner was the firft perfon who introduced the vaccine inoculation; and to him the public are alfo indebted for the firft careful and accurate inveftigation of this interefting fubject. The following is his account of the origin and hiftory of the difeafe, and of its characteriftic fymptoms.

4 Origin of the difeafe, according to him.

"There is a difeafe to which the horfe, from his ftate of domeftication, is frequently fubject. The farriers have termed it *the greafe*. It is an inflammation and fwelling in the heel, from which iffues matter poffeffing properties of a very peculiar kind, which feems capable of generating a difeafe in the human body (after it has undergone the modification which I fhall prefently fpeak of), which bears fo ftrong a refemblance to the fmall-pox, that I think it highly probable that it may be the fource of that difeafe.

Variolæ Vaccinæ.

“ In this dairy county (Glouceſterſhire), a great number of cows are kept, and the office of milking is performed indiſcriminately by men and maid ſervants. One of the former having been appointed to apply dreſſings to the heels of a horſe affected with *the greaſe*, and not paying due attention to cleanlineſs, incautiouſly bears his part in milking the cows with ſome particles of the infectious matter adhering to his fingers. When this is the caſe, it commonly happens that a diſeaſe is communicated to the cows, and from the cows to the dairy maids, which ſpreads through the farm until moſt of the cattle and domeſtics feel its unpleaſant conſequences. This diſeaſe has obtained the name of the

5 Its appearance on the cow and the perſon who milks her.

cow-pox. It appears on the nipples of the cows in the form of irregular puſtules. At their firſt appearance they are commonly of a paliſh blue, or rather of a colour ſomewhat approaching to livid, and are ſurrounded by an eryſipelatous inflammation. Theſe puſtules, unleſs a timely remedy be applied, frequently degenerate into phagedenic ulcers, which prove extremely troubleſome. The animals become indiſpoſed, and the ſecretion of milk is much leſſened. Inflamed ſpots now begin to appear on different parts of the hands of the domeſtics employed in milking, and ſometimes on the wriſts, which quickly run on to ſuppuration, firſt aſſuming the appearance of the ſmall veſications produced by a burn. Moſt commonly they appear about the joints of the fingers, and at their extremities; but whatever parts are affected, if the ſituation will admit, theſe ſuperficial ſuppurations put on a circular form, with their edges more elevated than their centre, and of a colour diſtantly approaching to blue. Abſorption takes place, and tumors appear in each axilla. The ſyſtem becomes affected, the pulſe is quickened, and ſhiverings, with general laſſitude, and pains about the loins and limbs, with vomiting, come on. The head is painful, and the patient is now and then even affected with delirium. Theſe ſymptoms varying in their degrees of violence, generally continue from one day to three or four, leaving ulcerated ſores about the hands, which, from the ſenſibility of the parts, are very troubleſome, and commonly heal ſlowly, frequently becoming phagedenic, like thoſe from whence they ſprung. The lips, noſtrils, eyelids, and other parts of the body, are ſometimes affected with ſores; but theſe evidently ariſe from their being needleſsly rubbed or ſcratched with the patient's infected fingers. No eruptions of the ſkin have followed the decline of the feveriſh ſymptoms in any inſtance that has come under my inſpection, one only excepted; and in this caſe a very few appeared on the arms: they were very minute, of a vivid red colour, and ſoon died away without advancing to maturation: ſo that I cannot determine whether they had any connection with the preceding ſymptoms.

“ Thus the diſeaſe makes its progreſs from the horſe to the nipple of the cow, and from the cow to the human ſubject.

6 Its ſingularity,

“ Morbid matter of various kinds, when abſorbed into the ſyſtem, may produce effects in ſome degree ſimilar; but what renders the cow-pox virus ſo extremely ſingular is, that the perſon who has been thus affected is for ever after ſecure from the infection of the ſmall-pox; neither expoſure to the variolous effluvia, nor the inſertion of the matter into the ſkin, producing this diſtemper.

Variolæ Vaccinæ.

7 Though is ſometimes confounded with other caſe.

“ It is neceſſary to obſerve, that puſtulous ſores frequently appear ſpontaneouſly on the nipples of cows; and inſtances have occurred, though very rarely, of the hands of the ſervants employed in milking being affected with ſores in conſequence, and even of their feeling an indiſpoſition from abſorption. Theſe puſtules are of a much milder nature than thoſe which ariſe from that contagion which conſtitutes the true cow-pox. They are always free from the bluiſh or livid tint ſo conſpicuous in that diſeaſe. No eryſipelas attends them, nor do they ſhew any phagedenic diſpoſition, as in the other caſe, but quickly terminate in a ſcab, without creating any apparent diſorder in the cow. This complaint appears at various ſeaſons in the year, but moſt commonly in the ſpring, when the cows are firſt taken from their winter food and fed with graſs. It is very apt to appear alſo when they are ſuckling their young. But this diſeaſe is not to be conſidered as ſimilar in any reſpect to that of which I am treating, as it is incapable of producing any ſpecific effects on the human conſtitution. However, it is of the greateſt conſequence to point it out here, leſt the want of diſcrimination ſhould occaſion an idea of ſecurity from the infection of the ſmall-pox, which might prove deluſive.”

Dr Jenner adds, that the active quality of the virus from the horſe's heels is greatly increaſed after it has acted on the nipples of the cow, as it rarely happens that the horſe affects his dreſſer with ſores, and as rarely that a milkmaid eſcapes the infection when ſhe milks infected cows. It is moſt active at the commencement of the diſeaſe, even before it has acquired a pus like appearance. Indeed the Doctor is rather induced to think that the matter loſes this property entirely as ſoon as it is ſecreted in the form of pus, and that it is the thin darkiſh looking fluid only, oozing from the newly formed cracks in the heels, ſimilar to what ſometimes exudes from eryſipelatous bliſters, which gives the diſeaſe. He is led to this opinion, from having often inſerted pus taken from old ſores in the heels of horſes, into ſcratches made with a lancet, on the ſound nipples of cows, which has produced no other effect than ſimple inflammation.

He is uncertain if the nipples of the cow are at all times ſuſceptible of being acted upon by the virus from the horſe, but rather ſuſpects that they muſt be in a ſtate of prediſpoſition, in order to enſure the effect. But he thinks it is clear that when the cow-pox virus is once generated, the cows, when milked with a hand really infected, cannot reſiſt the contagion, in whatever ſtate their nipples may chance to be. He is alſo doubtful whether the matter, either from the cow or the horſe, will affect the ſound ſkin of the human body; but thinks it probable that it will not, except on thoſe parts where the cuticle is very thin, as on the lips.

At what period the cow-pox was firſt noticed in Glouceſterſhire is not upon record. The oldeſt farmers were not unacquainted with it in their earlieſt days when it appeared upon their farms, without any deviation from the phenomena which it now exhibits. Its connection with the ſmall-pox ſeems to have been unknown to them. Probably the general introduction of inoculation firſt occaſioned the diſcovery. Dr Jenner conjectures that its riſe in that neighbourhood may not have been of very remote date, as the practice of milking cows might formerly have been in the hands of women

Variolæ Vacciniæ.

women only; and consequently the cows might not in former times have been exposed to the contagious matter brought by the men servants from the heels of horses. He adds, that a knowledge of the source of the infection is new in the minds of most of the farmers, but has at length produced good consequences; and that it seems probable, from the precautions they are now disposed to adopt, that the appearance of the cow-pox in that quarter may either be entirely extinguished or become extremely rare.

"With respect to the opinion adduced (Dr Jenner observes), that the source of the infection is a peculiar morbid matter arising in the horse; although I have not (says he) been able to prove it from actual experiments conducted immediately under my own eye, yet the evidence I have adduced appears to establish it.

"They who are not in the habit of conducting experiments, may not be aware of the coincidence of circumstances, necessary for their being managed so as to prove perfectly decisive; nor how often men engaged in professional pursuits are liable to interruptions, which disappoint them almost at the instant of their being accomplished; however, I feel no room for hesitation respecting the common origin of the disease, being well convinced that it never appears among the cows, except it can be traced to a cow introduced among the general herd which has been previously infected, or to an infected servant, unless they have been milked by some one who, at the same time, has the care of a horse affected with diseased heels."

The following case, which we also quote from Dr Jenner, would seem to shew that not only the heels of the horse, but other parts of the body of that animal, are capable of generating the virus which produces the cow-pox.

"An extensive inflammation of the erysipelatous kind appeared, without any apparent cause, upon the upper part of the thigh of a sucking colt, the property of Mr Miller, a farmer at Rockhampton, a village near Berkeley. The inflammation continued several weeks, and at length terminated in the formation of three or four small abscesses. The inflamed parts were fomented, and dressings were applied by some of the same persons who were employed in milking the cows. The number of cows milked was twenty-four, and the whole of them had the cow-pox. The milkers, consisting of the farmer's wife, a man, and a maid-servant, were infected by the cows. The man-servant had previously gone through the small-pox, and felt but little of the cow-pox. The servant-maid had some years before been infected with the cow-pox, and she also felt it now in a slight degree: but the farmer's wife, who never had gone through either of these diseases, felt its effects very severely. That the disease produced upon the cows by the colt, and from them conveyed to those who milked them, was the *true* and not the *spurious* cow-pox, there can be scarcely any room for suspicion; yet it would have been more completely satisfactory had the effects of variolous matter been ascertained on
8 the farmer's wife; but there was a peculiarity in her situation which prevented my making the experiment."

Jenner's opinion of the origin of the disease controverted.

Subsequent authors have not been all disposed to adopt Dr Jenner's opinion that this disease derives its origin from the grease in horses. We have seen the Doctor himself allow that he has not been able to prove it decisively by actual experiments; and to establish a fact so contrary to all analogy, perhaps no weaker evidence ought to be admitted. The only other bestial disorder with which we are acquainted, which is capable of being communicated by contagion to the human species, is hydrophobia: but here the disorder is the same in man as in the animal from which he derives it; and the analogy holds good in the propagation of the vaccine disease from the cow to her milker. But that the discharge from a local disease in the heel of a horse should be capable of producing a general disorder in the constitution of a cow, with symptoms totally different, and that this new disease once produced should be capable of maintaining an uniform character in the cow and in man, seems a much greater departure from the ordinary proceeding of Nature. We are very far from saying that this is impossible; for little indeed do we know of what Nature can or cannot do. All we mean to say is, that a fact so very extraordinary ought not to be hastily admitted.

In Holstein, we are told that the farmers do not know of any relation existing between the grease and the cow-pox, at least a person who resided three years in that country never heard of any. This, however, is certainly no proof. The same communication which contains this remark (a letter from Dr De Carro of Vienna to Dr G. Pearson) adds, "that in great farms men do not milk cows, but that in the smaller ones that happens very often; that a disease of horses, called *mauke* (true German name for *grease*), is known by all those who take care of them; that old horses particularly, attacked with the mauke, are always put in cow's stables, and there are attended by women; and that it is particularly in harvest that men in small farms milk cows." It must be allowed, then, that in this situation, supposing Doctor Jenner's opinion well founded, the cow-pox was naturally to be looked for, and here accordingly we find it. The question is certainly of no real utility, and therefore it has very properly been less attended to than other points respecting this disorder which lead to important practical conclusions.

Of all the questions which have arisen relative to the cow-pox, there is none so interesting, and luckily there is none which has received so full a discussion, or so satisfactory an answer, as the one we are now about to consider. Are those persons who have once had the cow-pox effectually and for ever secured against the variolous contagion?

Dr Jenner, in his first publication, was decidedly of opinion that a previous attack of this disorder rendered the human body for ever unsusceptible of the variolous virus; and besides the universal popular belief in the countries where cow-pox is known, he brought forward a number of cases in support of his assertion. By some of these it appeared that persons who had been affected with the cow-pox above twenty or thirty years before, continued secure against infection, either by the effluvia from patients under small-pox, or by inoculation. But along with this opinion he entertained other two, which, to many people, appeared so surprising as to take away all credit from the former. The first was, that a previous attack of small-pox did not prevent a subsequent attack of cow-pox; and the second was perhaps still more wonderful, that the cow-pox virus, although it rendered the constitution unsuscepti-

9 A previous attack of this disease renders the body unsusceptible of small-pox.

10 Difficulties explained.

 ble

ble of the ſmall pox, ſhould nevertheleſs leave it unchanged with reſpect to its own action, for that the ſame perſon is ſuſceptible of repeated attacks of the cow-pox.

Theſe opinions have been ſubmitted to the teſt of very extenſive experience by a variety of intelligent practitioners; and we think there can now be little doubt that the two laſt are erroneous, while the truth of the firſt has been eſtabliſhed by an immenſe body of incontrovertible evidence.

The opinions that a perſon who has had the ſmall-pox may afterwards have the cow-pox, and that the ſame perſon may have the cow-pox more than once, probably aroſe from the diſtinction between the local effects of the vaccine virus, and the general diſorder of the conſtitution not having been ſufficiently attended to. It is generally admitted, that in the inoculated ſmall-pox the local affection may go ſo far as that a puſtule ſhall ariſe on the part, containing matter capable of communicating the true ſmall-pox to others, and yet, if no general affection of the conſtitution takes place, the patient is not ſecure from the diſorder. In like manner, there are caſes upon record which prove that a perſon may, after having had the ſmall-pox, have a local affection produced by inoculation, in which true variolous matter ſhall be formed capable of communicating both the local and conſtitutional ſymptoms of ſmall-pox to others; and nurſes, when much expoſed to variolous contagion, often have an eruption reſembling ſmall-pox upon ſuch parts of their ſkin as have been expoſed to the action of the virus, though they have formerly undergone the diſeaſe. Yet there is probably no perſon at this day who will go ſo far as to aſſert that the ſame perſon can have the ſpecific variolous fever more than once.

The caſe ſeems to be preciſely the ſame with reſpect to cow-pox. Doctor Pearſon and others have inoculated a number of perſons after they have had the ſmall-pox with the vaccine virus, and have produced only the local affection; and by the ſame teſt it is aſcertained that the ſame perſon cannot more than once have the conſtitutional ſymptoms of the cow-pox. Dr Woodville indeed tells us that he has ſeen one caſe of genuine cow-pox puſtule and ſpecific fever in a conſtitution which had previouſly ſuffered the ſmall-pox. There can be no higher authority on this ſubject than that of Dr Woodville; and if he had actually ſeen his patient in the ſmall-pox as well as the cow-pox, we ſhould have admitted this ſingle caſe as completely deciſive of the queſtion. But the only evidence of this perſon having had the ſmall-pox, is the aſſertion of the patient that he had it *when a child*. This we can by no means ſuſtain as concluſive in oppoſition to the Doctor's own experience, as well as the experience of Dr Pearſon.

That the milkers are ſubject to repeated attacks of the local ſymptoms of cow-pox, whether they have had the ſmall-pox or not, is certain. In the caſe of the farmer's ſervants at Rockhampton, which we have quoted above from Dr Jenner, one of whom had previouſly undergone the ſmall-pox, and the other the cow-pox, and both of whom were afterwards infected by the cow-pox *in a ſlight degree*, it ſeems reaſonable to conclude that the local ſymptoms only were preſent in the laſt attack. We may at the ſame time obſerve, that in a caſe of this kind, where a very painful ulcer is produced in a very ſenſible part, this may probably be attended by an increaſed frequency of pulſe; yet if this has not the ſpecific marks of the cow-pox fever, we ſhould not ſay that ſuch a perſon has the diſorder conſtitutionally.

11 Succeſs of vaccine inoculation.

With reſpect to the principal propoſition, that the ſpecific fever of cow-pox renders the conſtitution unſuſceptible of the variolous fever, we think no doubt now remains. Above 1000 perſons who have undergone the vaccine inoculation have been afterwards inoculated with variolous matter, which has produced no other than local effects. Beſides theſe, there have been a vaſt number inoculated by private practitioners in different parts of the kindom, the reſult of which has not been reported. But we may ſafely ſuppoſe, that if any one of them had afforded a concluſion oppoſite to the one now generally admitted, it would have been communicated to the public.

We muſt not, however, conceal one ſeemingly well authenticated caſe which has lately occurred, and which, ſo far as it goes, certainly militates againſt this concluſion, and which, we doubt not, will be eagerly caught at by the opponents of the new practice. We quote it from the Medical and Chirurgical Review for September 1800.

12 A ſeemingly well authenticated exception.

"Mr Malim, ſurgeon of Carey Street, London, inoculated a child, two years and an half old, with vaccine matter procured from Dr Jenner. On the third day there were ſufficient marks of the action of the virus, and from this time to the end of the diſeaſe the local affection proceeded regularly and without interruption. On the eighth day the child complained of headache and ſickneſs; bad a quick pulſe, white tongue, and increaſed heat, with an enlargement and tenderneſs in the axilla. Theſe ſymptoms ſubſided in the courſe of the next day, and the child remained well till the twelfth, when it had a very ſevere attack of fever, ſucceeded, the following day by an eruption; the appearance, progreſs, and termination of which, left no doubt in the minds of ſeveral eminent practitioners of its being the ſmall pox. That it was really ſo, has been ſince clearly proved by inoculation. There was a child ill of ſmall-pox in the houſe at the time the above inoculation for cow-pox was performed."

The Reviewers juſtly remark, that the hiſtory is defective, in not deſcribing more minutely the appearances of the inoculated parts at the different ſtages, as well as in not mentioning the length of time that the matter had been taken previous to being uſed. Both theſe points are the more important, as a ſuſpicion naturally ariſes, that the local affection which ſucceeded the vaccine inoculation was not the genuine cow-pox puſtule, but one of the ſpurious kind, which had not the power of deſtroying variolous ſuſceptibility. The matter having been furniſhed by Dr Jenner, no doubt, renders this ſuppoſition the leſs probable; but if it was either long or improperly kept after it came out of his hands, it may have undergone a material change, by putrefaction or otherwiſe. Dr Jenner mentions an inſtance of a practitioner, who had been accuſtomed to preſerve variolous matter in a warm pocket; a ſituation favourable for producing putrefaction in it. This matter when inſerted, was found to produce inflammation, ſwellings of the axillary glands, fever, and ſometimes eruptions; but not of the true variolous kind, as patients thus inoculated iolæ inæ. lated were found ſtill ſuſceptible of the ſmall-pox contagion. It is ſurely a poſſible ſuppoſition, though merely a conjecture, that the vaccine matter in Mr Malim's caſe had undergone ſome ſuch change.

The caſe however, is in ſeveral reſpects an intereſting one. As it has been ſuppoſed that variolous contagion, communicated in the form of exhalation, does not affect the conſtitution in leſs than fourteen or fifteen days, and as the vaccine matter, communicated by inoculation, produces its ſpecific effects ſome days earlier, it has been ſuggeſted, that wherever a perſon has been accidentally expoſed to variolous effluvia, we ſhould endeavour to anticipate the ſmall-pox by immediately inoculating with the vaccine virus. But if there be nothing fallacious in the above caſe, it appears that this meaſure would not ſtop the progreſs of the ſmall-pox, but that our patient would incur the additional danger of having two diſeaſes inſtead of one.

3 bly ited At all events, it muſt be allowed that this child had been infected by the ſmall-pox before the vaccine matter had begun to produce its ſpecific effects, and probably even before the inoculation. Thus the ſmall-pox may be conſidered as having begun before the cow-pox; and though we ſhould be forced to allow that, matters being thus ſituated, the latter diſorder could not prevent the farther progreſs of the former, it by no means follows, that when the cow-pox has fairly run its courſe, the conſtitution is ſtill ſuſceptible of ſmall-pox. The two diſeaſes muſt have exiſted in this patient at the ſame time, though the one was in a latent ſtate during the active ſtage of the other.

This ſolitary caſe, then is by no means concluſive, and certainly is not ſufficient to outweigh the immenſe maſs of concurring evidence which is oppoſe to it.

4 nta- the prac- We proceed now to another highly important branch of our ſubject—the compariſon of the advantages and diſadvantages of the two diſeaſes, with a view to the practice of inoculation.

Notwithſtanding the immenſe number of caſes in which the inoculation of the cow-pox has been tried, we are not yet fully qualified to appreciate the value of the new practice; becauſe the diſeaſe has varied very much in ſeverity, and even in its moſt remarkable ſymptoms, and that without any cauſe which has yet been diſcovered.

Dr Jenner's account of the diſeaſe gave us reaſon to think that the local affection in cow-pox was more ſevere than in the inoculated ſmall-pox: That the fever in this diſeaſe was never attended with dangerous ſymptoms: that thoſe ſymptoms which affect the patient with ſeverity are entirely ſecondary, excited by the irritating proceſſes of inflammation and ulceration: that the diſeaſe was not attended with any eruption reſembling ſmall-pox: and that the ſore produced by the inoculation was apt to degenerate into a very diſtreſſing phagedenic ulcer, which required to be treated with applications of a cauſtic nature, of which he found the unguentum hydrargyri nitrati the moſt uſeful.

Soon after Dr Jenner's publication, the attention of medical men was forcibly drawn to the ſubject; and ſeveral eminent practitioners in London, particularly Dr George Pearſon, and Dr Woodville phyſician to the ſmall-pox and inoculation hoſpitals, immediately began to practiſe the vaccine inoculation. The latter gentleman ſoon publiſhed an accurate and candid account of the effect of this virus upon 200 patients, with a table of the reſults of above 500 caſes in which the inoculation was performed. Variolæ Vaccinæ.

15 Anomalies in the progreſs of the diſeaſe. It is very remarkable, that in none of theſe caſes did the inoculated part ulcerate in the manner deſcribed by Dr Jenner, nor did the inflammation ever occaſion any inconvenience, excepting in one inſtance, in which it was ſoon ſubdued by the aqua lythargiri acetati. The general affection of the conſtitution, on the other hand, though in a great majority of caſes it was very ſlight, yet, in ſome inſtances, was ſevere. An eruption, exactly reſembling ſmall-pox, was, contrary to expectation, a very common occurrence, and in ſome the puſtules were not fewer than 1000; and although in theſe caſes the diſeaſe was ſtill unattended with ſecondary fever, yet the febrile ſymptoms which took place from the commencement were conſiderable, and even alarming, as ſometimes alſo happens with the inoculated ſmall-pox.

Dr Woodville ſometimes inoculated with matter from the primary ſore in the arm, and ſometimes with matter taken from the puſtular eruption; and it appears from the table that a much larger proportion of thoſe who were inoculated in the latter way had puſtules, than of thoſe who were inoculated either with matter immediately from the cow, or from the primary ſore in the human body. There were 447 patients in all inoculated, either from the cow or from the primary ſore; and of theſe 241 had puſtules, and 206 had none. Sixty-two perſons, on the other hand, were inoculated with matter from the puſtules of ten different patients; and of theſe no fewer than 57 had puſtules, and only 5 eſcaped without. Nor can it be ſaid that this diſproportion aroſe from theſe 10 patients having the diſeaſe in a more virulent form than ordinary, for matter was alſo taken from the primary ſore in 4 of the 10, with which 48 were inoculated; of whom 27 had puſtules, and 21 had none: whereas, of 9 perſons who were inoculated with matter from the puſtules of theſe ſame 4, only 2 eſcaped without puſtules. This obſervation correſponds alſo with Dr Pearſon's experience.

Although theſe eruptions have been met with by other practitioners, yet they certainly appear very rarely in private practice. Dr Woodville, for this reaſon, conſiders them, in a more recent publication as the effect of ſome adventitious cauſe, independent of the cow-pox: And this he ſuppoſes to be the variolated atmoſphere of the hoſpital, which thoſe patients were neceſſarily obliged to inſpire during the progreſs of the cow-pox infection. This opinion, however, does not ſeem to agree well with his former remark, which, as we have ſaid, is confirmed, by Dr Pearſon, that eruptions rarely took place, if care was taken to avoid matter for inoculation from ſuch as had puſtules; a fact that cannot be explained on ſuch a ſuppoſition. Neither is this idea reconcileable with what he alſo tells us, that the proportion of caſes in the hoſpital attended with puſtules, has been of late only three or four in a hundred.

This change in the appearances of the diſeaſe in the hands of different practitioners, and even of the ſame practitioner at different times, is one of the moſt unaccountable circumſtances reſpecting this ſingular diſorder.

Variolæ Vaccinæ.

der. There is fome curious information on this fubject, contained in a letter from Mr Stromeyer of Hanover to Mr Hannehmaun.

"This year (fays he) we have inoculated 40 perfons, as well with the vaccine matter received of Dr Pearfon as with that from Dr Jenner; all of whom underwent the difeafe properly.

"Betwixt the London and Gloucefter vaccine matter, it appears to me there fubfifts an effential difference. The London matter produces frequently an eruption of fmall pimples; but they difappear within a day or two at fartheft. Dr Pearfon calls thefe eruptions *puftules*.—The Gloucefter matter has never produced this effect here; but *frequently occafioned ulcerations of the inoculated part, of a tedious and long duration; which the latter never did*: on account of which I now only make ufe of Dr Pearfon's vaccine matter. The nettle-fever-like eruptions I have obferved feveral times, but never that fort of eruption, repeatedly noticed in London, which fo much refembles the fmall-pox."

If thefe obfervations of Mr Stromeyer fhould be confirmed by the experience of others, they would go far to explain the difference which the London practitioners have found in this difeafe from the account given of it by Dr Jenner, notwithftanding the abfence of the eruption refembling fmall-pox at Hanover. We believe an interchange of vaccine matter has once or twice taken place between London and Gloucefterfhire. Is it fince that period that the eruption has been lefs frequent at London? Dr Pearfon is inclined to fuppofe, that the comparative feverity of the difeafe at London, during the firft winter, arofe rather from the difference in the human conftitution at the different feafons of the year, than from any change in the ftate of the vaccine matter.

16
Mortality from the old practice over-rated by the advocates for the new.

In comparing the degree of danger from the inoculation of cow-pox with that arifing from the inoculated fmall-pox, we are convinced that Dr Pearfon greatly over-rates the mortality in the latter diforder. He fuppofes it to be no lefs than one in 200. Dr Mofeley, on the other hand, who is a violent opponent of the vaccine inoculation, afferts, that he has inoculated feveral thoufands with variolous matter, in Europe and the Weft Indies, without ever lofing a patient and that feveral other perfons, whom he knows, have done the fame, with the fame fuccefs. We are afraid, however, that the experience of other inoculators does not afford fo favourable a refult. We believe that in this country the mortality is often occafioned by improper treatment; and from comparing the accounts which we have received from practitioners of extenfive experience, and undoubted veracity, we believe that, where the treatment is proper from the beginning, the fymptoms very rarely arife to an alarming height, and that the mortality is not fo great as one in 600. And this eftimate nearly correfponds with Dr Woodville's very great experience. It muft be allowed, that patients in an hofpital are fubject to fome difadvantages, which may be avoided in private practice; yet, out of the laft 5000 cafes of variolous inoculation at the inoculation hofpital, prior to the publication of the Doctor's reports, the mortality did not exceed one in 600.

Notwithftanding this ftatement, however, we are happy to fay, that the danger in the vaccine difeafe is ftill much lefs. Dr Pearfon tells us, that in little more than fix months after the new inoculation was introduced into London, which includes the period at which the cow-pox affumed the moft unfavourable appearance, 2000 perfons at leaft underwent the operation; of thefe, one only, an infant at the breaft, under the care of Dr Woodville, died. In this folitary fatal cafe, the local tumor was but very inconfiderable; and the eruptive fymptoms took place on the feventh day, when the child was attacked with fits of the fpafmodic kind, which recurred at fhort intervals, with increafed violence, and carried it off on the eleventh day after the cow-pox matter had been infected into its arm, and after an eruption of about 80 puftules had appeared.

17
Great fuccefs of new inoculation.

Since that time a much greater number, amounting certainly to feveral thoufands have been inoculated with cow-pox in different parts of Great Britain and on the continent. Among thefe, not one fatal inftance, that we have heard of, has occurred.

But even if the danger to the individual from the fmall-pox and from the cow-pox were equal, there is an important advantage to the public attending the latter, which we think would alone be fufficient to intitle it to a preference—It is not capable of being propagated by the effluvia arifing from the bodies of perfons infected with it. There are many fituations in which a prudent furgeon will be reftrained from inoculating with fmall-pox, left the contagion fhould fpread to other people, who may be either prevented by prejudice from fubmitting to the operation, or in whom it would be obvioufly improper, from the circumftances of age, teething, or the prefence of fome other difeafe. Here the cow-pox virus may be fubftituted with great propriety. It is chiefly from this quality that the cow-pox bids fair to extirpate the fmall-pox entirely.

This valuable property of the vaccine diforder is not, however, to be admitted without fome limitation. When it produces numerous puftules on the body, Dr Woodville tells us, that the exhalations they fend forth are capable of affecting others in the fame manner as the fmall-pox. Two inftances of cafual infection in this way have fallen under his obfervation. In one, the difeafe was fevere, and the eruption confluent; in the other, the difeafe was mild, and the puftules few. It has been remarked, that the inoculated cow-pox is little if at all, different from the difeafe when cafually caught. But, ftrictly fpeaking, the above are the only two cafes in which the difeafe has been communicated otherwife than by inoculation.

18
Whether the cow-pox and fmall-pox ought to be confidered as different difeafes.

The writers upon this fubject are divided in opinion, whether the cow-pox and fmall-pox ought to be confidered as different difeafes, or whether they are merely varieties of the fame difeafe.

They certainly, notwithftanding the ftrong analogy which fubfifts between them, differ from each other in feveral ftriking particulars. The cow-pox comes to man from the cow, and is capable of being carried back from him to that animal. Similar attempts with variolous matter have failed: in this refpect, then, thefe two morbid poifons are altogether different.

The local tumor produced by the inoculation of the cow-pox is commonly of a different appearance from that which is the confequence of inoculation with variolous matter: for if the inoculation of the cow-pox be performed by a fimple puncture, the confequent tumor, in the proportion of three times out of four, according riolæ cinæ. cording to Dr Woodville, aſſumes a form completely circular, and it continues circumſcribed, with its edges elevated and well defined, and its ſurface flat, through every ſtage of the diſeaſe; while that which is produced from the variolous matter, either preſerves a peculiar form, or ſpreads along the ſkin, and becomes angulated, or irregular, or disfigured by numerous veſiculæ. Another diſtinction ſtill more deciſive and general, is to be drawn from the contents of the cow-pox tumor; for the fluid here formed very rarely becomes puriform; and the ſcab which ſucceeds is of a harder texture, exhibits a ſmoother ſurface, and differs in its colour from that which is formed by the concretion of pus. The appearances, however, are ſometimes ſo changed, that they can in no reſpect be diſtinguiſhed from thoſe which ariſe from the inoculation of ſmall-pox. We may alſo mention that the tendency of the ſore in the inoculated part to degenerate into a phagedenic ulcer does not occur in ſmall-pox.

On the other hand, the points in which theſe two diſeaſes reſemble each other are very remarkable. When introduced into the body by inoculation, they affect the conſtitution in nearly the ſame length of time, and ſeem to be governed by nearly the ſame laws. They mutually deſtroy the ſuſceptibility of the body for the action of each other.

Dr Pearſon, who thinks the diſeaſes ought to be conſidered as diſtinct ſpecies, neverthele ſs draws the following concluſions, as eſtabliſhed by experience.

"That in certain conſtitutions, or under the circumſtances of certain co-operating agents, *the vaccine poiſon produces a diſeaſe reſembling the ſmall-pox;* and of courſe the puſtule in the inoculated part is *very different from that of the vaccine pox ordinarily occurring*, and the eruptions *reſemble very much, if not exactly, ſome varieties of the ſmall-pox:* That in ſome inſtances theſe eruptions have occurred, although the inoculated part exhibited the genuine vaccine puſtule: That the matter of ſuch eruptive caſes, whether taken from the inoculated part, or from other parts, produces univerſally (A), or at leaſt generally, ſimilar eruptive caſes; and has not (he believes) been ſeen to go back, by paſſing through different conſtitutions, to the ſtate in which it produces what is called the *genuine vaccine diſeaſe:* That eruptions, of a different appearance from variolous ones, ſometimes occur in the true cow-pox."

19 ...are ...ably varie- ...f the dis- From theſe facts we are ſtrongly inclined to think that the vaccine diſeaſe and the ſmall-pox ought merely to be conſidered as varieties of the ſame diſeaſe; and we have little doubt that they both derive their origin from the ſame ſource.

If Dr Jenner's opinion, that the vaccine diſeaſe is derived from *the greaſe*, were fully eſtabliſhed, we ſhould be diſpoſed to offer a conjecture, that the *ſmall pox*, in coming from the horſe to man, may have paſſed through ſome animal different from the cow, and may thus have undergone a modification ſimilar to, but not exactly, the ſame with what takes place in the paſſage of the virus through the conſtitution of the cow.

But without having recourſe to this conjecture, which is perfectly gratuitous, we are of opinion that the variations which have taken place in the cow-pox within the laſt three years are ſufficient to warrant a belief, that the ſmall-pox may have originally been exactly the ſame diſeaſe, even in the human conſtitution, as the cow-pox is now; but that in a ſucceſſion of ages, and from the operation of cauſes wholly unknown to us, it may have been changed to what we now ſee it. Variolæ Vaccinæ.

We ſhall now conclude this article with a few practical remarks, which we hope may be of uſe to practitioners who mean to begin the vaccine inoculation.

It is of the utmoſt conſequence that the matter employed ſhould be the genuine vaccine virus. Dr Jenner points out the following particulars as ſources of a ſpurious cow-pox: 1. That ariſing from puſtules on the nipples or udder of the cow, which puſtules contain no ſpecific virus. 2. From matter, although originally poſſeſſing the ſpecific virus, which has ſuffered a decompoſition, either from putrefaction, or any other cauſe leſs obvious to the ſenſes. 3. From matter taken from an ulcer in an advanced ſtage, though the ulcer aroſe from a true cow-pox. 4. From matter produced on the human ſkin from the contact of ſome peculiar morbid matter generated by a horſe. 20 Practical remarks.

Many have remarked that inoculation with the vaccine matter is more apt to fail in communicating the infection than with variolous matter, eſpecially if it be ſuffered to dry upon the lancet before it is uſed. This does not ſeem to depend upon the virus of the former being more volatile, but upon its becoming more hard and indiſſoluble upon exſiccation. Care ſhould therefore be taken to moiſten it a conſiderable time before it is uſed.

We have already noticed the danger that may ariſe from miſtaking the local effects of the vaccine diſeaſe for its effects upon the conſtitution. To guard practitioners againſt this error, Dr Woodville makes the following remarks: "When a conſiderable tumor and an extenſive redneſs take place at the inoculated part, within two or three days after the infectious matter has been applied, the failure of inoculation may be conſidered as certain as where neither redneſs nor tumor is the conſequence. This rapid and premature advancement of the inflammation will always be ſufficient to prevent the inoculator from miſtaking ſuch caſes for thoſe of efficient inoculation. But there are other circumſtances under which I have found the inoculation to be equally ineffectual, and which, as being more likely to deceive the inoculator, require his utmoſt circumſpection and diſcrimination. I here allude to caſes in which it happens that though the local affection does not exhibit much more inflammation than is uſual, yet neither veſicle nor puſtule ſupervenes; and in which, about the ſixth or ſeventh day, it rapidly advances into an irregular ſuppuration, producing a feſtering or cruſtaceous ſore. Care, however, ſhould be taken to diſtinguiſh this caſe from that in which the inoculated part aſſumes a puſtular form, though it continues for one or two days only, when the ſame appearances follow as thoſe above deſcribed; for I have experienced the latter inoculation to be as effectual as where the tumor has proceeded in the moſt regular manner."

"The

(A) We have ſeen that Dr Woodville's table contains a few exceptions to this rule, though it ſtrongly confirms the general truth of the propoſition.

"The efflorescence at the inoculated part, which seldom intervenes before the eighth, or later than the eleventh day, is to be regarded as an indication that the whole system is affected; and if the patient has not felt any indisposition on or before its approach, he may be assured that there will not be any afterwards. When efflorescence does not commence till the eleventh day, it is almost always attended with more indisposition than when it occurs on the eighth or ninth day. The efflorescence is more frequent in young infants than in children advanced to three or four years of age; and the former have the efflorescence, and the disease more favourably than the latter, insomuch that by far the greater part of them have no perceptible illness, and require no medicines. On the other hand, in adults, the cow-pox frequently produces headache, pain of the limbs, and other febrile symptoms, for two or three days, which are greatly relieved by a brisk purgative."

Since the above was written, vaccination has been extended all over Europe and into many parts of Asia. It has been practised on a very large scale in the West India islands, with the most complete success. In the United States it has been extensively adopted with the happiest effects. Doctor J. R. Coxe of Philadelphia and Doctor Waterhouse of Cambridge, Massachusetts, have particularly distinguished themselves by their zeal and activity in extending the knowledge and practice of vaccination, and the medical gentlemen generally throughout the union, have laudably co-operated with them to extend the benefit of this most important discovery in all the states. Many thousands have been inoculated and have had the disease in the regular form, and from the numerous trials which have been fairly made, there is no room to doubt of its being a complete preservative against the small-pox, and from the rapidity with which this beneficial practice is extending there is every reason to expect that it will soon be universally established.

We would, upon the whole, recommend the vaccine inoculation to our medical readers as being an effectual preventative against the small pox, and safer to the individual, while it is more advantageous to the public at large, in being less capable of propagation by contagion.

UCAH, *Port*, on the N. W. coast of North-America, is situated on Washington's Island, south of Port Geyer, and north of Port Sturgis. At its mouth are Needham's Isles. The middle of the entrance of this bay is in lat. 52 25 N.—*Morse.*

UCAYALA *River*, a south branch of Amazon river.—*ib.*

UCHE, an Indian town situated on the Chata Uche river. It is situated, according to Bartram, on a vast plain, and is the largest, most compact, and best situated Indian town he ever saw. The habitations are large and neatly built; the walls of the houses are constructed of a wooden frame, then lathed and plaistered inside and out with a reddish well tempered clay or mortar, which gives them the appearance of red brick walls; and the roofs are neatly covered with cypress bark, or shingles. The town appears populous and thriving, full of youth and young children; and is supposed to contain about 1500 inhabitants. They are able to muster 500 gunmen or warriors. Their national language is radically different from the Creek or Muscogulge tongue, and is called the Savanna or Savanuca tongue. It is said to be the same or a dialect of the Shawanese. Although in confederacy with the Creeks, they do not mix with them; and are of importance enough to excite the jealousy of the whole Muscogulge confederacy, and are usually at variance, yet are wise enough to unite against a common enemy to support the interest of the general Creek confederacy.—*ib.*

VASE *River*, *Au*, empties into the Mississippi from the N. E. 3 miles below the Great Rock, about 55 N. W. by N. of the mouth of the Ohio, and about the same distance N. W. of Fort Massac. It is navigable into the N. W. Territory about 60 miles, through a rich country, abounding in extensive natural meadows, and numberless herds of buffaloe, deer, &c. It is about 8 miles above Cape St Antonio.—*ib.*

VASSALBOROUGH, a post-town of the district of Maine, in Lincoln county, on Kennebec river, half way between Hallowell and Winslow, 204 miles N. by E. of Boston, and 551 from Philadelphia. It was incorporated in 1771, and contains 1,240 inhabitants. —*ib.*

VAUCLIN *Bay*, on the east coast of the island of Martinico. Vauclin Point forms the south side of Louis Bay, on the east coast of the same island.—*ib.*

VAVAOO, one of the Friendly Islands in the South Pacific Ocean. It is about two days sail from Hapaee. —*ib.*

VEALTOWN, a village of New-Jersey, near Baskenridge, about 7 miles south-westerly of Morristown. —*ib.*

VEAU, *Anse a*, a village on the north side of the south peninsula of the island of St Domingo, 5 leagues west by north of Miragoane, 4½ eastward of Petit Trou, and 19 north-east of Les Cayes.—*ib.*

VECTOR, or Radius Vector, in astronomy, is a line supposed to be drawn from any planet, moving round a centre, or the focus of an ellipse, to that centre or focus. It is so called, because it is that line by which the planet seems to be carried round its centre; and with which it describes areas proportional to the times.

VEGA, or *Conception of la Vega Real*, a town in the north-east part of the island of St Domingo, on the road from St Domingo city to Daxabon. It is situated near the head of Yuna river, which empties into the bay of Samana; 12 leagues north-west by west of Cotuy, and about 38 easterly of Daxavon, or Daxabon. It stands on a beautiful plain among the mountains, on the very spot where *Guarionex*, cacique of the kingdom of Magua, had resided. In 1494, or 1495, the settlement of this town was begun by Columbus. Eight years after, it had become a city of importance, and some times during the year, there were 240,000 crowns in gold, minted at this place. It was almost destroyed by an earthquake in 1564.—*Morse.*

VEGETABLES. } See *Vegetable Substances* in
VEGETATION. } this *Suppl.*

VEJAS, or *Morro de Vejas*, on the coast of Peru, is about half a league from the island of Lobos.—*Morse.*

VELA, a cape on the coast of Terra Firma, S. America, in about lat. 12 N. and long. 72 W. and about 18 leagues N. by E. of the town of La Hacha.—*ib.*

VELAS,

VELAS, or *Velasco*, a port on the west coast of New-Mexico, is 7 leagues north-west by north of the Morro Hermosa, and 8 from St Catharine's Point.—*ib.*

VELICALA, a town on and near the head of the peninsula of California, near the coast of the N. Pacific Ocean, and northerly from Anclote Point. N. lat. about 20 35, W. long. 115 50.—*ib.*

VENEZUELO, a province of Terra Firma, bounded east by Caracas, south by New-Grenada, west by Rio de la Hacha, and on the north by the North Sea. It abounds with game and wild beasts, producing plenty of corn twice a year, with fruits, sugar, and tobacco, and the best cocoa plantations in America. It spreads round a gulf of the same name that reaches near 30 leagues within land; and the middle of this country is occupied by a lake 20 leagues long, and 30 broad, with a circumference of 80, and navigable for vessels of 30 tons. It communicates with the gulf by a strait, on which is built the city of Maracaibo, which gives name to both lake and strait, which is defended by several forts which were attacked in the last century by Sir Henry Morgan, and the whole coast laid under contribution, and Maracaibo ransomed. The province is about 100 leagues in length, and as much in breadth. It had its name from its small lagoons, which make it appear like Venice at the entrance of the lake. The Spaniards massacred above a million of the natives in 1528. In 1550, the country was again depopulated; when a great number of black slaves were brought from Africa, and was one of the principal epochs of the introduction of negroes into the West Indies. Soon after, a revolt of the negroes was the cause of another massacre, and Venezuelo became again a desert. At present it is said to contain about 100,000 inhabitants, who live tolerably happy, and raise great numbers of European sheep. They cultivate tobacco and sugar, which are famous over all America. They manufacture also some cotton stuffs. It has many populous towns, and its waters have gold sands. Its capital, of the same name, or Cora, stands near the sea coast, about 50 miles south-east of Cape St Roman, N. lat. 10 30, W. long. 70 15.—*ib.*

VENEZUELO, a spacious gulf of the same province, communicating by a narrow strait with Maracaibo Lake.—*ib.*

VENTA *de Cruz*, a town on the isthmus of Darien, and Terra Firma. Here the Spanish merchandise from Panama to Porto Bello is embarked on the river Chagre, 40 miles south of the latter, and 20 north of the former. N. lat. 9 26, west long. 81 36.—*ib.*

VENTILATION OF SHIPS is a matter of so great importance, that we would rather hazard the stating of an idle project for this purpose, than omit any thing which may be useful. We hazard nothing, however, in stating the following plan by Mr Abernethy, who candidly acknowledges that it is built upon the principles which we, together with the learned editor of Chambers's Cyclopædia, have borrowed from Dr Hailes. This plan consists merely in causing two tubes to descend from above the deck to the bottom of a vessel, or as low as ventilation is required; and which should communicate by smaller pipes (open at their extremities) with those places designed to be ventilated. There should be a contrivance for stopping these communicating pipes, so that ventilation may be occasionally prevented from taking place, or confined to any particular part of the vessel.

One of the principal air tubes should descend as near to the stern of the vessel as convenient, and the other as near to the stem.

Through that tube which is in the head, the foul air is to be extracted; and through that which is in the stern, the fresh air is to descend to the different decks and other apartments of the vessel.

The extraction of the air is easily effected in the following manner: Let a transverse tube be fitted to that which descends in the head of the vessel: it may be sunk within the level of the deck, so as to cause no inequality of surface. Let it be continued till it comes beneath the fire place, then ascend in a perpendicular direction through the fire, and open a little above it; or it may be made to communicate with the chimney. It would be more convenient if the fire was near the place where the tube rises through the deck; but the experiment must equally succeed, if the tube be made to descend again till it is beneath the common fire-place. The effect that will result from this contrivance is obvious; when the tube which passes through the fire is heated, the air will ascend with a force proportionable to its levity, and the ascending column can only be supplied from below, consequently it must come from all those parts of the ship with which the main tube communicates.

When the ports are open, the quantity of air thus exhausted from the ship will be supplied from all quarters; but if they were all shut, and the hatchways and other openings completely closed, the renewal of fresh air is made certain by means of the tube which descends in the stern. The main air tube, where it rises above the deck in the stern, should have an horizontal one fitted to it, which might be made to traverse, so that it could be turned to windward; it might also expand at its extremity like the mouth of a trumpet; and thus perfectly fresh air must enter, and the force of the gale would tend to impel it into the vessel.

When that part of the tube which passes through the fire is red hot, the draught which would be thus occasioned might perhaps be too great, and the open pipes which communicate with the decks might emit and imbibe the fresh air in so direct a stream, that it might be injurious to those persons within the current.

Mr Abernethy therefore thinks it would be better if those smaller pipes which lead from the main tubes were made to run along the decks and communicate with them by numerous orifices. Two pipes opening into the main exhausting tube might be extended along the tops of the deck, in the angle formed between the sides and the ceiling: and thus the air would be extracted equally from all parts, and in a manner not likely to occasion injurious currents. Some division of the stream of air which enters from the stern might also be made, if it were thought necessary.

Thus a very complete, and in no way injurious, ventilation may be obtained: the air in the vessel would be perfectly changed when the fire was strong, without expense or trouble; and a gradual and salubrious alteration of it might at all times be made, by a very little additional quantity of fuel. The air tubes should consist of separate joints, so that occasionally they might be taken to pieces; and to prevent their being injured or

Ventilation.

or put out of order by rough ufage, the copper pipes fhould be made of confiderable ftrength, placed againft the fides of the veffel, and even incafed in wood.

In the Letters and Papers of the Bath Society, &c. we have the following defcription of a ventilator for preferving corn on fhip board, by Thomas South, Efq:

Plate XLVII.

Fig. 1. is a cylindrical air-veffel, or forcing pump, of lead, tin, or other cheap metal; its internal diameter being ten inches, and its length three feet; having a crutch-handled pifton to work with, and an iron nofle, *viz.* a hollow inverted cone, two feet long, to condenfe the air, and increafe its power in its paffage downwards. This cylinder fhould be rivetted or fcrewed, by means of an iron collar or ftraps, to the deck it paffes through, both above and below, as at *a a*; and fhould be farther fecured by fome holdfaft near *b*, to keep it fteady in working.

Fig. 2. is a bottom of wood, four inches and a half thick, with a projecting rim at its bafe, for the metal cylinder to reft on when cemented and fcrewed to the wood. The centre of this bottom is excavated, for the reception of the crown of the nofle. In the fame figure the nofle is reprefented with its crown like a bowl difh, to condenfe the air gradually, without refiftance, in its advance to the more contracted bafe of the inverted cone, *i. e.* the top of the entrance of the nofle. About two-thirds down this nofle may be fixed a male fcrew, as *c c*, for the purpofe hereafter mentioned.

N. B. The forcing-pump fhould be cafed in wood, to protect it from outward bruifes, which would prevent the working of the pifton, and ruin its effects. The leather round the embolus fhould be greafed when ufed.

Fig. 3. is a crutch-handle, faftened to the embolus A by its iron legs B, B. A is a cylinder of wood, cafed with leather, fo as to fit well, but glide fmoothly, in the metal cylinder; having an opening as large as its ftrength will permit, for the free accefs of atmofpheric air. C is a valve well leathered on its top, and yielding downwards to the preffure of the air when the pifton is raifed up. D is a crofs bar of iron, to confine the valve, fo that it may clofe inftantly on the return of the pifton downwards.

Fig. 4. is a tin pipe or tube, of lefs than four inches diameter, and of fuch length, as when fixed to the bafe of the cylinder, fig. 1. fhall admit the nofle *d*, fig. 2. to within half an inch of the valve E, at the bottom of the wooden cylinder F, in fig. 4; which valve E will then yield to the preffure of air condenfed in its paffage through the nofle, and deliver it into the pipes below. This valve muft be well leathered on its upper furface, and faftened with an hinge of leather to the cylinder it is meant to clofe: affixed to its bottom is the fpindle G, paffing through a fpiral fpring H, which, being compreffed on the defcent of the valve, will, by its elafticity, caufe it to rife again, clofe the aperture above, and retain the air delivered beneath it. On connecting this cylinder with the upper end of the nofle, at *e e*, fig. 2. we muft carefully prevent any lapfe of air that way, by a bandage of oakum fmeared with wax, on which to fcrew the cylinder, like the joints of a flute, air-tight. I is a bar of iron, having a rifing in its centre, wide enough for the fpindle to play through, but at the fame time fufficiently contracted to prevent the paffage of the fpiral fpring.

Fig. 5. is an affemblage of tin pipes, of any lengths, fhaped fuitably and conveniently to their fituation in the fhip, to the form of which, when fhut into one another, they muft be adapted; obferving only, that the neck be ftraight for a length fufficient to admit the lower end of the cylinder, fig. 4. as high as the letter F, or higher.

Fig. 6. To the middle pipe, which runs along the bottom, fhould be fixed a perpendicular one, fully perforated, to convey the air more readily into the centre of the heap; and this may have a conical top, as reprefented in the Plate, perforated with a fmaller punch to prevent the air from efcaping too haftily. In large cargoes, two or three of thefe perpendiculars may be neceffary; and each fhould be well fecured by an iron bar *g*, fcrewed down to prevent their being injured by the fhifting of the cargo in ftormy weather or a rolling fea. The top of the conical cap of thefe pipes may reach two-thirds up the cargo.

Fig. 7. is a valve of the fame conftruction as that reprefented in fig. 4. but inclofed in a tube of brafs, having a female fcrew at *f f*, adapted to the male fcrew *c c*, on the nofle fig. 2. and may then be inferted into the head of the pipe fig. 5. This will add to the expenfe; but in a large apparatus is to be preferred, as a more certain fecurity from lapfe of air, than the junction of the tube fig. 4. to the neck *e e* in fig. 2.

N. B. *e e* is a neck of wood, making a part of the bottom fig. 2. whereon to fecure the tube fig. 4. when applied to the nofle. The joints of the pipes, when put together for ufe, fhould be made air-tight, by means of bees wax or fome ftronger cement, till they reach the bottom of the veffel, when there is no farther need of this precaution. The horizontal pipes fhould run by the fide of the kelfon the whole length of the hold. The tin plates of which K is made, fhould be punched in holes, like the rofe of a watering-pot, in two or three lines only at moft, and then formed into a tube, with the rough fide outwards. L may have four or five lines of the like perforations. M, and the reft, fhould gradually increafe in their number as they advance towards the middle of the hold, and continue fully perforated to the laft pipe which fhould be clofed at its end to prevent the ingrefs of the corn. It is the centre of the cargo which moft requires ventilating, yet air fhould pervade the whole. Like the trade winds, it will direct its courfe to the part moft heated, and, having effected its falutary purpofe there, will difperfe itfelf to refrefh the mafs.

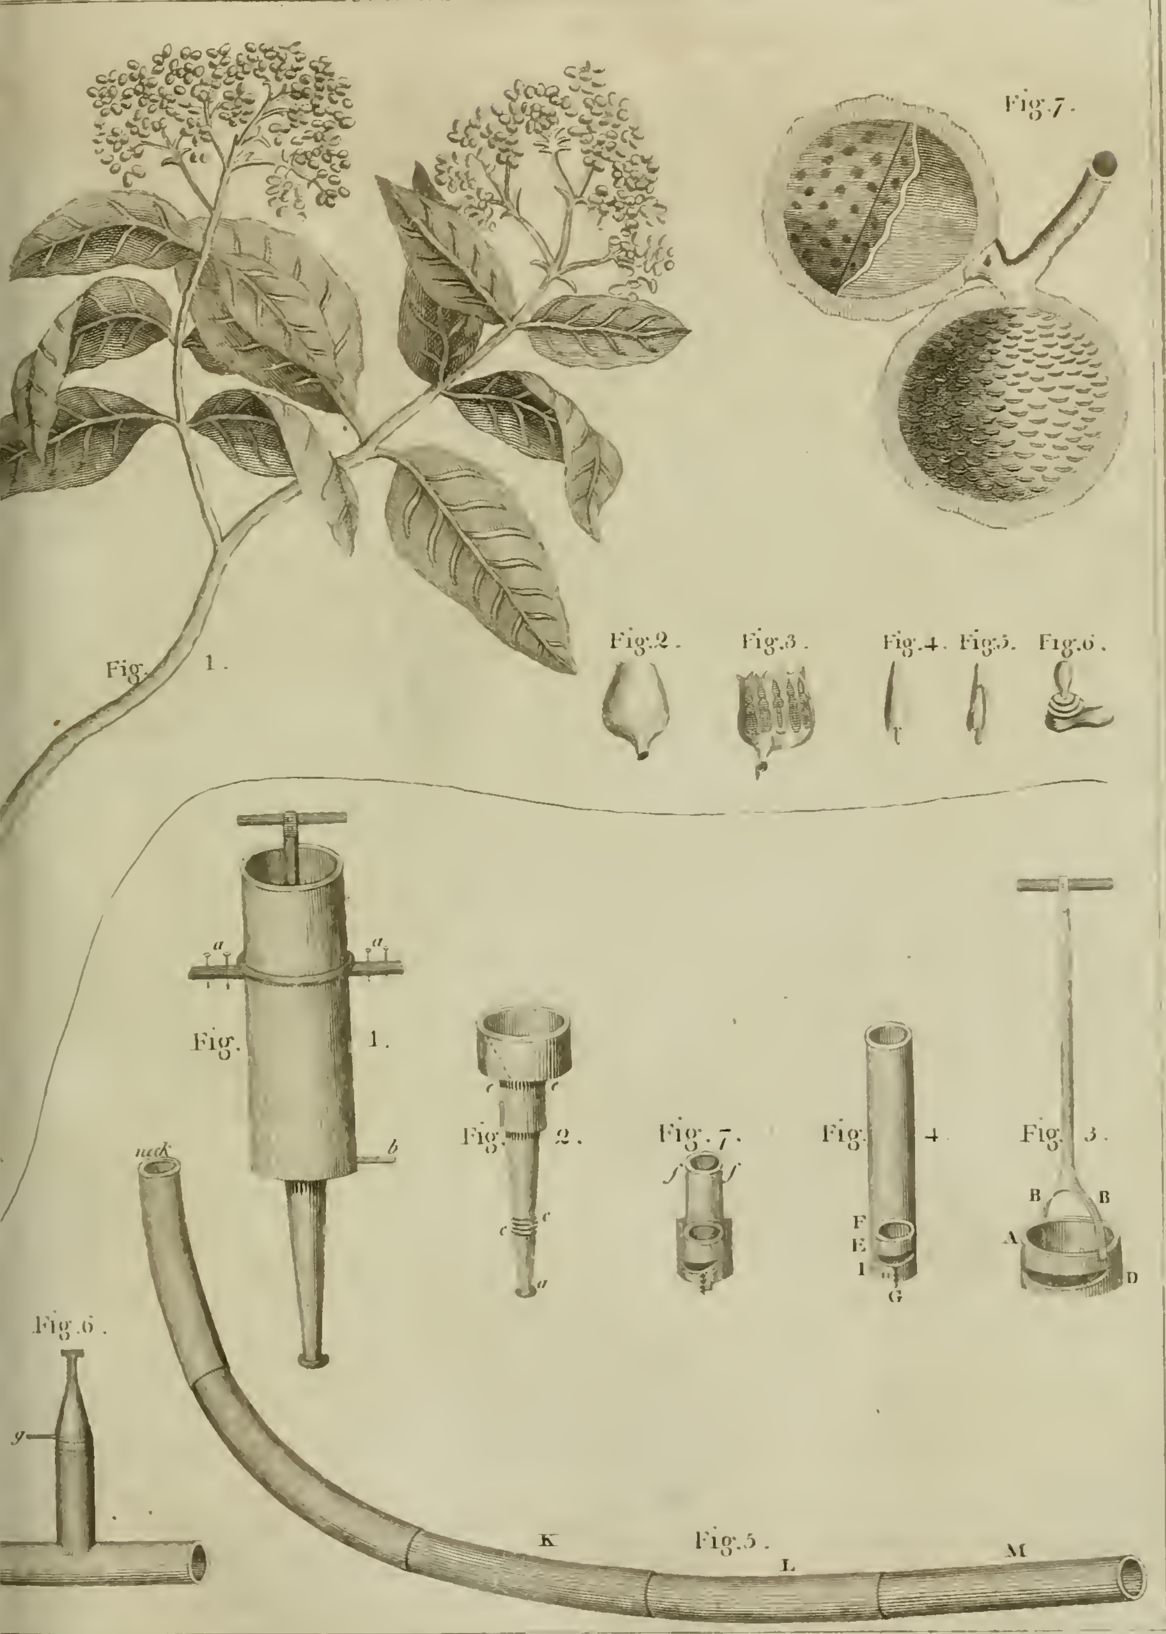
Where the hatches are clofe-caulked, to prevent the influx of water, vent-holes may be bored in convenient parts of the deck, to be bunged up, and opened occafionally, from whence the ftate of the corn may be known by the effluvia which afcend when the ventilator is working.

The power of the ventilator is determined by the fquare of its diameter multiplied into the length of the ftroke, and that again by the number of ftrokes in any given time.

The air-veffel or forcing-pump, with the reft of the apparatus here defcribed, is adapted to a veffel of 120 tons burden; but by lengthening the air-veffel, extending its diameter to 14 inches, and adding 10 inches more to the length of the ftroke, a power may be obtained of ventilating a cargo of 400 tons within the hour.

If

URCEOLA ELASTICA. PLATE XLVII.



If this machine be properly wrought for one hour every day, or even every two days, beginning the operations immediately when the corn is put on board, the cargo may be preserved from taint or injury of every kind during the longeſt voyage.

VENTO *Sierra*, on the north coaſt of S. America, are mountains ſo named, behind the land called Punta de Delrio, oppoſite to Tortugas Iſland.—*Morse.*

VENUS, *Point*, in Otaheite Iſland, in the ſouth Pacific Ocean, is the eaſt point of Matavai or Port Royal Bay, and north point of the iſland. S. lat. 17 29, W. long. 149 36.—*ib.*

VERA *Cruz*, *La*, the grand port of Mexico, or New Spain, having a ſafe harbour protected by a fort, ſituated on a rock of an iſland nearly adjoining, called St John de Ulloa, in the Gulf of Mexico. It is, perhaps, one of the moſt conſiderable places for trade in the world, being the natural centre of the American treaſure, and the magazine for all the merchandize ſent from New Spain, or that is tranſported thither from Europe. It receives a prodigious quantity of Eaſt India produce by way of Acapulco, from the Philippine Iſlands. Moſt of its houſes are built of wood, and the number of Spaniſh inhabitants is about 3,000, mulattoes and mungrels, who call themſelves white. It is rather unhealthy, from the rank bogs around it. N. lat. 19 12, weſt long. 97 30. It is in the eaſt extremity of the province of Tlaſcala, or Los Angelos. At the Old Town, 15 or 16 miles further weſt, Cortez landed on Good Friday, 1518, when, being determined to conquer or die, he ſunk the ſhips that tranſported his handful of men hither. La Vera Cruz is 215 miles ſouth-eaſt of the city of Mexico.—*ib.*

VERAGUA, by Ulloa made a province of Terra Firma, in S. America, but others have it as a province of Guatimala and New Spain, in North-America; joining on the W. to Coſta Rica; on the E. to Panama; with the North Sea on the north; and the South Sea on the ſouth. The coaſt was firſt diſcovered by Chriſtopher Columbus in 1503, to whom it was granted with the title of Duke, and his poſterity ſtill enjoy it. The province is very mountainous, woody and barren; but has inexhauſtible mines of ſilver, and ſome gold, the duſt of the latter being found among the ſands of the rivers. Santiago de Veraguas, or Santa Fe, the capital, is but a poor place; and in this province is the river Veragua, on which that town ſtands.—*ib.*

Veragua, the river above mentioned, empties into the ſea 18 leagues to the ſouth-eaſt of the river or lake of Nicaragua, in lat. 10 5 N. Here is a very good port; but the iſland at its mouth is foul. The beſt anchorage is on the weſt and ſouth ſides next the main, where ſhips may ride under ſhore in from 8 to 9 fathoms, and ſafe from the north and eaſterly winds, that are moſt violent on this coaſt. Several iſlands lie off from the coaſt, both ſingly and in cluſters, from this to Cape Gracias a Dios; and to the eaſtward from hence is Chagre river.—*ib.*

VERA *Paz*, a province of the audience of Guatimala, and New Spain, in N. America. It has the bay of Honduras and Chiapa on the north, Guatimala on the ſouth, Honduras on the eaſt, and Soconuſca, with part of Chiapa, on the weſt. It is 48 leagues long, and 28 broad. The lands are mountainous, yielding little corn, but abounding in cedar, &c. The principal commodities are drugs, cocoa, cotton, wool, honey, &c. Its capital of the ſame name, or *Coban*, ſtands on the weſt ſide of a river which runs into Golfo Dulce, 184 miles eaſt of Guatimala. N. lat. 15 10, W. long. 93 15 — *ib.*

VERDE, or *Green Iſland*, on the N. coaſt of S. America, is at the mouth of the river St Martha.—*ib.*

Verde *Key*, one of the Bahama Iſlands. N. lat. 22 12, W. long. 75 15.—*ib.*

Verde, Porto, or *Vedra*, is on the N. Atlantic Ocean, about 4½ leagues S. E. by E. of Rio Roxo. The iſland of Blydones is at the entrance of this port, round which ſhips may ſail on any ſide, there being 7 fathoms on the N. where it is ſhoaleſt, and 20 fathoms on the S. ſide, where is the beſt entrance into the river. This is a port of good trade, and ſometimes large ſhips put in here. The iſlands of Bayonne are 5 leagues to the S. of the iſland in the mouth of the port.—*ib.*

VERDEN, a duchy of Germany, in the circle of Lower Saxony. It is bounded on the eaſt and ſouth by that of Lunenberg; on the weſt, by the Weſer and the duchy of Bremen; and on the north, by the duchies of Bremen and Lunenburg; extending both in length and breadth about 28 miles. It conſiſts chiefly of heaths and high dry lands; but there are good marſhes on the rivers Weſer and Aller. In 1712, the Danes wreſted this duchy from Sweden, and, in 1715, ceded it to the king of Great Britain, as elector of Hanover; which ceſſion, in 1718, was confirmed by the Swedes. The inhabitants are Lutherans.

VERDERONNE, or *La Bourlarderie*, an iſland on the E. coaſt of Cape Breton Iſland. It is 7 or 8 leagues long; and at each end is a channel, through which the waters of the Labrador Lakes, in the inner part of Cape Breton Iſland, diſcharge into the ocean on the eaſt.—*Morse.*

VERDIGRIS, or Acetite of Copper. See that article, *Encycl.* where an account is given of the proceſs by which verdigris was long manufactured. A different, and more economical proceſs, however, has for ſome years been practiſed in Montpellier, which is worthy of notice, becauſe it may be adopted in this country by ſubſtituting the huſks of gooſeberries or currants for thoſe of grapes.

In the manufacture of verdigris, the materials are copper and the huſks of grapes after the laſt preſſing. The copper is formed into round plates, half a line in thickneſs, and from twenty to twenty-five inches in diameter. Each plate, at Montpellier, is divided into twenty-five laminæ, forming almoſt all oblong ſquares of from four to ſix inches in length, three in breadth, and weighing about four ounces. They are beat ſeparately with a hammer on an anvil to ſmooth their ſurfaces, and to give the copper the neceſſary conſiſtence. Without this precaution it would exfoliate, and it would be more difficult to ſcrape the ſurface in order to detach the oxydated cruſt. Beſides this, ſcales of pure metal would be taken off, which would haſten the conſumption of the copper.

The huſks, which ſhould not be too much preſſed are firſt made to ferment by being put into cloſe vats, and the fermentation is generally completed in three or four days. The time, however, muſt vary according to the temperature

temperature in which they are kept, and other circumstances. Whilst the husks are fermenting, a preliminary preparation is given to the copper plates. This consists in dissolving verdigris in water in an earthen vessel, and rubbing over each plate with a piece of coarse linen dipped in this solution. The plates are then immediately placed close to each other, and left in that manner to dry. Sometimes the plates are only laid on the top of the fermented husks, or placed under those which have been already used for causing the copper to oxydate. It has been observed, that when this operation has not been employed. the plates grow black at the first operation, instead of becoming green. It is not, however, necessary to those which have been once used, and are to be used again.

When the plates are thus prepared, and the husks have been brought to ferment, the workmen try whether the latter are proper for the process, by placing under them a plate of copper, and leaving it buried there for twenty-four hours. If the plate, after this period, is found covered with a smooth green crust, in such a manner that none of the metal appears, they are then thought fit for being disposed in layers with the copper. On the other hand, if drops of water are observed on the surface of the plates, the plates are said to *sweat*, and it is concluded that the heat of the husks has not sufficiently subsided. They consequently defer making another trial till the next day. When they are assured that the husks are in a proper state, they form them into layers in the following manner:

The plates are all put into a box, which, instead of having a bottom, is divided in the middle by a wooden grate. The plates disposed on this grate are so strongly heated by a chaffing-dish placed under them, that the woman employed in this labour is sometimes obliged to take them up with a cloth, in order that she may not burn her hands. As soon as they have acquired that heat, they are put into jars in layers with the husks. Each jar is then closed with a covering of straw, and left to oxydate. Thirty or forty pounds of copper, more or less according to the thickness of the plates, are put into each jar. At the end of ten, twelve, fifteen, or twenty days, the jar is opened; and if the husks are white, it is time to take out the plates. The crystals are then seen detached, and of a silky appearance on their surface. The husks are thrown back, and the plates are put in what is called *relai*. For that purpose they are immediately deposited in a corner of the cellar on sticks ranged on the floor. They are placed in an upright position, one leaning against the other; and at the end of two or three days they are moistened, by taking them up in handfuls and immersing them in water in earthen pans. They are deposited quite wet in their former position, and left there for seven or eight days; after which they are once or twice immersed again. This immersion and drying are renewed six or eight times every seven or eight days. As the plates were formerly put into wine, these immersions were called *one wine*, *two wines*, *three wines*, according to the number of times. By this process the plates swell up, the green is nourished, and a coat of verdigris is formed on all their surfaces, which may be easily detached by scraping them with a knife.

This verdigris, which is called *fresh* verdigris, *moist* verdigris, is sold by the manufacturers to people who dry it for foreign exportation. In this first state it is only a paste, which is carefully pounded in large wooden troughs, and then put into bags of white leather, a foot in height and ten inches in diameter. These bags are exposed to the air or the sun, and are left in that state till the verdigris has acquired the proper degree of dryness. By this operation it decreases about 50 *per cent.* more or less according to its primitive state. It is said to stand proof by the knife, when the point of that instrument pushed against a cake of verdigris through the skin cannot penetrate it. White lead may be made by a similar process.

Crystallized VERDIGRIS is manufactured at Montpellier in the following manner: A vinegar, prepared by the distillation of sour wine, is put into a kettle, and boiled on the common verdigris. After saturation the solution is left to clarify, and then poured into another kettle of copper, where it is evaporated till a pellicle forms on the surface. Sticks are then immersed into it, and by means of some packthread are tied to some wooden bars that rest on the edge of the kettle. These sticks are about a foot long, and are split cross-wise nearly two inches at the end, so that they open into four branches, kept at about the distance of an inch from each other by small bags. The crystals adhere to these sticks and cover them entirely, forming themselves into groups or clusters, of a dark blue colour, and a rhomboidal shape. Each cluster weighs from five to six pounds. Three pounds of moist verdigris are required for one pound of the crystals; the undissolved residuum is thrown away.

VERDUN, an ancient, strong, and considerable town of France, in the department of Meuse, and late province of Lorrain, with a bishop's see, and a strong citadel. Its fortifications were constructed by the Chevalier de Ville and Marshal de Vauban. The latter was a native of this place. In 1755, great part of the cathedral was destroyed by lightning. Verdun was taken by the Prussians in 1792, but retaken by the French soon after. The inhabitants are noted for the fine sweetmeats they make. It is seated on the river Maese, which runs through the middle, 42 miles southwest of Luxemburg, and 150 east of Paris. E. Lon. 5° 28′ N. lat. 43° 9′.

VERE, a parish of the island of Jamaica, having Manury Bay in it; a very secure road for shipping —*Morse*.

VERGENNES, a post-town, and one of the most growing and commercial towns of Vermont, in Addison county, on Otter Creek, about 6 Miles from its mouth in Lake Champlain. It is regularly laid out, and contains a Congregational church, and about 60 houses. In its neighbourhood are several mills. It is 115 miles north of Bennington, 22 S. of Burlington, and 407 N. E. by N. of Philadelphia. The township contained 201 inhabitants in 1790.—*ib.*

VERINA, a small village, and Spanish plantation of New-Andalusia, and Terra Firma, S. America. Its tobacco is reputed the best in the world. It lies 60 miles east of Cumana.—*ib.*

VERMEJA, or *Vermillion Bay*, on the north shore of the Gulph of Mexico, or coast of Louisiana. It is to the N. W. of Ascension Bay, in about lat. 30 N. and long. 92 W.—*ib.*

VERMEJO, or *Bermejo*, an island and port on the coast

coast of Peru, 2 degrees N. and a little west of Lima. It is 4 leagues from Mongon on the north, and 6 from Guarmey Port on the south.—*ib.*

VERMIFUGE, a medicine which expels worms from the intestines. Of these medicines numbers are daily advertised in the newspapers as infallible, though the ingredients of which they are composed are carefully kept secret. We think it our duty therefore to assure our readers, that the medicines vended by quacks are generally the very same that would be prescribed by a regular physician for the disease in which they are pretended to be specifics, with this only difference, that the unseen and unprincipled quack generally prescribes them in more powerful doses than the regular physician deems safe for his patient. Thus Ching's famous worm medicine, which has been so strenuously recommended, is nothing more than mercury given in the very same form in which it is given by every physician; but Ching gives it in doses, which, though they have not injured the children of a bishop and a judge, we have *known* to *salivate* other children to the great hazard of their lives. It is indeed wonderful that parents should trust the health and the lives of their children to men whom they never saw, and whom they know to be not oppressed with an over delicate sense of honour, in preference to a man of science who has a character to support, and who is probably their friend, and almost always their acquaintance.

Of the different vermifuges, however, it must be confessed that the greater number are liable occasionally to fail. One of the most powerful which we have mentioned in the article MEDICINE, *Encycl.* is composed of the spiculæ of the *cowhage* or *cow-itch*; and since that article was published, it has come more into use, chiefly through the recommendatiun of Mr Chamberlaine surgeon. He says that a tea spoonful of the electuary (See MEDICINE, *Encycl.* p. 342.) may be safely given to a young child, and one or even two table spoonfuls to adults. The medicine is to be taken in the morning fasting; and the dose to be repeated for two or three mornings, after which a gentle purge completes the cure. This medicine, however, Mr Chamberlaine prohibits in every case where there is a tendency to inflammation in any part of the intestinal canal, or where the mucus has been carried off or greatly diminished by dysentery or any other cause.

Dr Haemmerlin of Ulm has lately recommended as a very powerful and safe vermifuge the coraline of Corsica, and says that it has been so used in that island with complete success from time immemorial. It is a fucus adhering to the rocks washed by the sea, and sometimes to the stones and shells thrown upon the shore. It is found in little tufts. It is generally of a yellow colour, with a reddish tincture. When dried, as it appears when offered for sale, it contains a strong smell of the sea. It consists of little cartilaginous stalks, with full threads, gradually cylindrical and tubulated. Its taste is salt and unpleasant. In the system of plants of Linnæus, it belongs to the class *cryptogamia*. Its most common names are, sea rock moss; the Grecian herb; lemithochorton; and the coraline of Corsica. It is the *conferva helminthortos* of Schwendimann, and the *fucus helminthocorton* of Latourette. There is reason to think that all those species of fucus whose texture is soft and spungy, might be applied to the same medicinal uses. There is a sort of red coraline found in Sweden which, according to some writers, is a greater destroyer of worms than any other known substance; being not too strong for the stomach either of infants or of adults. Schwendimann asserts that the *conferva dichotoma* of Linnæus, which is found in the ditches in England, bears a strong analogy to the coraline of Corsica. Might not this conferva be tried as a vermifuge? The Corsican coraline is in great estimation in the pharmacopœias of the Continent, especially in that of Geneva, in which is given a recipe for preparing a syrup of it.

VERMILLIAS *Barrycras*, on the coast of Brazil, between the Island of St John's and Sypomba Island, which are 7 leagues asunder. Here is a large bay with good anchorage.—*Morse.*

VERMILLION, *Point*, called also Long Point, is the peninsula between Bay Puan and Lake Michigan. —*ib.*

VERMILLION *River*, in the N. W. Territory, runs north-westward into Illinois river, nearly opposite the S. W. end of Little Rocks, and 267 miles from the Mississippi. It is 30 yards wide, but so rocky as not to be navigable.—*ib.*

VERMILLION *Indians* reside 220 miles up the Miami of the Lake.—*ib.*

VERMONT, one of the United States of North America, lies between 42° 44′ and 45° N. lat. and 1° 43′ and 3° 36′ E. lon. from Philadelphia. It is in length 158 miles, and breadth 70 (A) containing between 900 and 1000 square miles. It is bounded north, by Lower Canada; east, by Connecticut River, which divides it from New Hampshire; south, by Massachusetts; west, by New York.

Vermont is naturally divided by the Green Mountain, which runs from south to north, and divides the state nearly in the middle. It is at present divided into the following counties, which lie in a circuit as you proceed from Bennington county, north, on the west side of the Green Mountains to the Canada line, then east to Connecticut river; then south, along the river to the Massachusetts line, viz. Bennington, Rutland, Addison, Chittendon, Franklin, Orleans, Essex, Caledonia, Orange, Windsor and Windham.

The towns are incorporated and organized much in the same manner as the towns in Massachusetts and Connecticut. In each of the towns granted by the governor of New Hampshire, while this territory was under the jurisdiction of that province, in number 114, there is a reserve of one right of land, in fee, usually containing 330 acres, for the first settled minister in such town; one right, as a glebe, for the church of England; one right to the society in Great Britain for the propagation of the gospel in foreign parts; and one right for the support of a school in the town. In the remaining towns granted by the State of Vermont, there is one right for the use of an university; one for the use of schools, in each town; one for the use of county

(A) The northern line, separating Vermont from Canada, is 90 miles long. The southern line, dividing Vermont from Massachusetts, is 40 miles in length. In the middle 55 miles.

Vermont. county grammar schools, and one for the support of the gospel.

Lake Champlaine, more than half of which lies within the state of Vermont, from Whitehall, formerly Skeensborough, at the southern extremity, including South Bay, to latitude 45°, is one hundred miles in length. It is about 14 miles in breadth in the widest place(B). Lake Memphremagog lies partly in the state of Vermont, and partly in Lower Canada, the line crossing it about 7 miles from the southern extremity. This lake communicates with the St Lawrence, by the river St Francis. There are numerous small lakes and ponds of less note, some of the principal of which are, Willoughby's lake, in Westmore, and Bell-water lake in Barton; the former furnishes fish resembling bass, some weighing 23 pounds. They make a delicious feast for the new settlers. People travel 20 miles to this lake to procure a winter's stock of this fish. Leicester Pond or Lake, in the town of Salisbury, is remarkable for the depth and transparency of its waters, and for a large species of trout which it produces, some of which have been found to weigh above nineteen pounds. Lake Bombazon, in Castleton, gives rise to a branch of Poultney river, on which iron works have been erected in Fair Haven; and a large pond in the town of Wells. Lake Pleasant in Greensborough, abounds in trout of one or two pounds weight, many barrels of which are caught in a season.

Few countries are better watered than the state of Vermont. Numerous perennial fountains rise on almost every farm. In this state is the height of land, between Connecticut, Hudson and St Lawrence. Streams descend from the mountains in various directions, and form numerous small rivers, which fertilize the lands through which they pass and furnish abundant conveniences for mills and founderies. The river Connecticut forms the eastern boundary of Vermont. From its present importance to the commerce of this state, and the opening of an Inland navigation from Hartford in Connecticut, to Barnet in Vermont, more than 100 miles from the south line of this state, which has lately been effected, it merits to be noticed in this place. This river has its source in the high lands which divide the waters falling southward into the Atlantic, from those which fall into the St Lawrence, about 50, others say 25, miles north of latitude 45°. From its northernmost part, to latitude 45° it is the boundary between the United States and the British dominions in America. The eastern, or principal branch of Connecticut river rises in New Hampshire, and runs north, then making a semi-circle, turns to the south, and runs nearly south about 40 miles below lat. 45°; then about 40 more it runs S. W. till it comes to Haverhill; then it runs south to Northfield; below Northfield is a very large bend to the westward, and soon after to the east again. Thence it proceeds, with some meanders, about Northampton and Hadley, nearly south to Hartford, and thence southeasterly to Saybrook, where it empties itself into the sound. Its length, from its source to the sea, including all its turnings, is nearly four hundred miles, and it crosses four parallels of latitude. Loaded boats ascend from Hartford in Connecticut, to the mouth of Wells river, and even as far as Barnet near the foot of the falls, about two hundred and twenty miles from the sea. In this course the navigation is interrupted by the Falls at Hadley, (which in one place descend *thirty feet*, and with amazing grandeur, though not in a continued sheet. The descent is greater than in any one place at Bellows Falls) Miller's Falls, at and near Northfield; Bellows Falls, between Rockingham in Vermont, and Walpole in New Hampshire; Queechy Falls, a little below the mouth of the river of that name, and White River Falls, four and an half miles below Dartmouth College. Companies have been formed by the several states of Massachusetts, New Hampshire and Vermont, for the purpose of removing these obstructions; and their object is now nearly accomplished. All the falls in this river, except Queechy and White River Falls, are locked.

The falls of Queechy are but a slight obstruction. The falls or rapids of White River, have three distinct bars, which make a portage of three miles. In some parts, the water falls 20 feet.

At the mouth of Queechy, commonly called Water Queechy river, there is one of the most beautiful cascades in New England. The river, here about 258 feet wide, pours over a ledge of rocks 40 feet high, in an almost perpendicular manner, just broken enough to throw the water in every fantastical and delightful form.

Many smaller rivers fall into Connecticut river, Memphremagog, Lake Champlaine, and the Hudson.

The south branch of Nullegan rises in Random, and interlocks with the head of the Clyde. By these rivers the Indians formerly came in canoes from Lake Memphremagog to Connecticut river; the carrying place from one river to the other is about a mile. It crosses the line between Random and Caldersburgh.

The rivers and lakes abound with various kinds of fish. Shad are taken in Connecticut river, as high as Bellows Falls, over which they never pass. Salmon in plenty have heretofore been caught in the spring, the whole length of Connecticut river, and in most of its tributary streams; but few, however, of late years. A small species of salmon is taken in Lake Champlaine, the Winouski, or Onion river, La Moille and Missiscoui, but in none of the southern rivers. Perch, pike, pickerel, maskinungas, a very large species of pickerel, pout, mullet, and a fish called lake bass, are found in great plenty. All the streams abound with salmon-trout.

There are handsome bridges built over the Connecticut at Bellows Falls, Windsor and Hanover.

Besides the numerous springs of fresh water, there are some chalybeate springs. There is a spring in Orwel, near

(B) The state of New York has, by an act of the legislature, established a company for the purpose of opening an inland navigation, by the Hudson, from Lansingburgh to fort Edward, and from fort Edward to Wood Creek and Lake Champlaine. The work is now in forwardness, and, when completed, will open to Vermont a water communication with Lansingburgh, Albany and New York: The whole of this inland navigation will be three hundred and seventy miles, from latitude 45° to New York.

 near Mount Independence, and another in Bridport, which produce the Epfom falts.

There is alfo a curious mineral fpring on fome low land over againft the great Ox Bow, difcovered about the year 1770.

Vermont is divided, from north to fouth, by a high chain of mountains. This chain has, from the evergreens with which it is covered in many places, obtained the name of *Green Mountain*, from which the name of *Vermont* is derived to the ftate. The fouthern extremity is called Weft Rock, a precipice about three miles from New Haven, in Connecticut; thence the mountain ranges northward, rifing in height, as it advances through Connecticut, Maffachufetts and Vermont. The hills in Fairfield county are a principal branch, on the coaft of the Green Mountains. Towards Lake Memphremagog it fpreads into a high plain country, exceedingly fertile, and paffes into the province of Quebec. After having formed the rapids of St Francis, it collects into a high range of mountains, which terminate near the St Lawrence. From Maffachufetts line, more than 80 miles to the north, the weftern verge of the Green Mountain is from twenty to thirty miles on a ftraight line from Connecticut river. Almoft the whole of this country is formed with mountains ranging parallel with the courfe of Connecticut river. The weft range, which continues unbroken, with few exceptions, nearly through the ftate, is, in general, much the higheft. On the eaft they decreafe gradually to the meadows, and fometimes to the edge of the river. Thefe laft are interfected by the rivers which run into the Connecticut, in a direction nearly from the northweft to the foutheaft. The vallies, or rather glens, which feparate thefe ranges, are generally narrow, and moftly covered with hemlock, fir and fpruce.

About 100 miles from Maffachufetts line, between the waters of White river and Winoufki, or Onion river, there paffes off to the northeaft, a range of high lands, frequently rifing into very elevated mountains. This runs parallel with Connecticut river; the height being from ten to fifteen miles diftant, as far as the north line of the ftate. The weftern range continues northward, fometimes falling below the clouds, fometimes rifing above them. Between thefe two ranges, extending from twenty to thirty miles in breadth, is a beautiful champaign country, fecond in fertility, perhaps, to none in Vermont.

The moft remarkable mountains in the ftate, are Mount Anthony, between Bennington and Pownal, Stratton Mountain, Danby Mountain, Kellington Peaks, Kingfton Mountain, Camel's Rump, Mansfield Mountain, a very high mountain between Kelly Vale and Belvidere, Upper Great Monadnock, quite in the N. E. corner of the ftate, and Afcutney, between Windfor and Weatherfield. On the weft of the Green Mountain, there is one, and in fome places, two or three ranges of fmaller mountains, though frequently interrupted. Thefe extend as far as the north line of the county of Rutland: From that, to the latitude of forty-five degrees, one hundred miles in length, and from twenty to thirty miles in breadth, between Lake Champlaine and the Green Mountain, is a fine tract of land, abounding with only moderate hills. Through this whole extent, few tracts can be found unfit for cultivation.

It is remarkable that the hills and mountains are generally covered on the eaft fides with what is called hard wood, fuch as birch, beach, maple, afh, elm, and butternut; the weft fide is generally covered with evergreens.

The climate, foil, productions, and animals differ little from thofe in New England.

The trade from this ftate is principally to Hartford, Bofton and New York. Some little trade is carried on with the province of Quebec. The remittances to Quebec are moftly made in lumber, fuch as boards, plank, fquare timber and ftaves, by Lake Champlaine and the St Lawrence. The articles of export to Hartford, Bofton, Portland and New York, are horfes, beef, pork, butter, cheefe, wheat, wheat flour, iron, nails, pot and pearl afhes. Of the two laft articles, one thoufand tons were made in the ftate in the year 1791.

The number of people in Vermont, according to the cenfus taken in 1790, was 85,589. The inhabitants of Vermont confift principally of emigrants from Maffachufetts and Connecticut, and their defcendants. There have been fome from Rhode Ifland, New Hampfhire, New York, and New Jerfey. Two towns in Caledonia county are moftly peopled from Scotland, and are Prefbyterians, partly of the Seceffion, and partly of the covenanted Church. The manners of the people are the fame as thofe of the ftates from whence they emigrated. The body of the inhabitants are congregationalifts. The other denominations are baptifts, epifcopalians, quakers, and a few methodifts. The ftate is rapidly peopling. In 1788, the townfhip of Danville, in the county of Orange, was a wildernefs without a fingle family. In 1792 they had two confiderable companies of militia; befide a company of light infantry, dreffed in uniform.

The inhabitants of this ftate are an affemblage of people from various places, of different fentiments, manners and habits. They have not lived together long enough to affimilate and form a general character. Affemble together, in imagination, a number of individuals of different nations; confider them as living together amicably, and affifting each other through the toils and difficulties of life, and yet rigoroufly oppofed in particular religious and political tenets; jealous of their rulers, and tenacious of their liberties, (difpofitions which originate naturally from the dread of experienced oppreffion, and the habit of living under a free government)—and you have a pretty juft idea of the character of the people of Vermont. Indolence is never a characteriftical feature of the fettlers of a new country. Emigrants in general are active and induftrious. The oppofite characters have neither fpirit nor inclination to quit their native fpot. The inference is, that Vermont is peopled with an active, induftrious, hardy, frugal race; as is really the cafe. And as it is a maxim that the inhabitants of all new countries grow virtuous before they degenerate, it will moft probably be fo in Vermont.

The inhabitants of the feveral towns feem generally difpofed, as foon as they are able, to fettle a minifter of the gofpel among them. Miffionaries, from Connecticut and Maffachufetts, to the new and fcattered fettlements, have been generally well received and treated with grateful refpect and kindnefs.

In 1796 there were, on the militia rolls, 19,500 men. Thefe were formed into 4 divifions, confifting of 8 brigades

Vermont. gades and 22 regiments. The increaſe ſince may be eſtimated according to the increaſe of inhabitants. The bravery of the *Green Mountain Boys* is proverbial.

In a new country, like Vermont, few have leiſure to attend the arts and ſciences beyond the preſent occaſions of life. The higher branches of learning are therefore very little taught in this ſtate. Numbers, however, are educated in the ſeminaries of the neighbouring ſtates. In October, 1791, the legiſlature of the ſtate paſſed an act for eſtabliſhing a univerſity at Burlington, on Lake Champlaine, in a delightful ſituation, on the ſouth ſide of the Winouſki, or Onion river, and appointed 10 truſtees. The ſum of ſix thouſand pounds was ſecured by donation, part of which was to be applied to the erecting of buildings, and part ſettled as a fund for the ſupport of the inſtitution. There have been reſerved in the ſeveral grants made by this ſtate about thirty-three thouſand acres of land, for the uſe of the univerſity. This in a few years, will become a very valuable fund. There is in every town, granted by the ſtate, conſiſting of about one hundred, a right of land, containing about three hundred and thirty acres, on an average, reſerved for the uſe of county grammar ſchools; and in every town through the ſtate, there is a right for the ſupport of town ſchools. In no country is common ſchooling more attended to. A family of children, who could not read, write, and underſtand common arithmetic, would be looked upon as little better than ſavages. The proviſion, in this reſpect, is certainly worthy of imitation. The inhabitants of each town are empowered by law to divide it into as many diſtricts as ſhall be found convenient; to appoint one or more perſons in each diſtrict, who, with the ſelectmen of the town, form a board of truſtees for the ſchools of that town; and are empowered to leaſe all lands and loan monies that belong to the town, for the uſe of ſchools, and to proſecute or defend any ſuit or matter relating to their truſt. The inhabitants of each diſtrict have likewiſe a power to appoint a committee of one or more perſons, to raiſe by tax, on the rateable eſtates of the inhabitants of the diſtrict, one half of the ſum which they may find neceſſary for building a ſchool-houſe and ſupporting a ſchool. The remainder of the money is to be raiſed by ſubſcription, or, if voted by two-thirds of the inhabitants, by a tax in like manner. By theſe means, every claſs of citizens may have acceſs to the common ſchools.

In five counties, grammar ſchools have been eſtabliſhed, viz.

Towns.	Counties.	Years.
At Norwich,	Windſor,	1785.
Caſtleton,	Rutland,	1787.
Peacham,	Caledonia,	1795.
Middlebury,	Addiſon,	1797.
St Alban's,	Franklin,	——

The Middlebury academy in 1800, was, by act of Aſſembly, erected into a college with the uſual charter privileges, and is now flouriſhing under the government and inſtruction of a preſident and ſubordinate officers. The college edifice is the largeſt in the ſtate.

The academy at Peacham is very flouriſhing, and has ample funds in lands appropriated by charter, as has been mentioned. The annual rent of theſe lands, it is expected will, when the lands ſhall be leaſed, yield an annual income of eight or nine hundred dollars. A handſome donation of a farm, worth 1200 dollars, has lately been made by Mr James Orr, deceaſed, of Barnet, originally from Scotland. A large and convenient building has been erected for the accommodation of the ſtudents.

A Medical Society was inſtituted in this State in 1784, and another in 1794.

The inhabitants of Vermont, by their repreſentatives in convention, at Windſor, on the 25th of December, 1777, declared that the territory called Vermont, was, and of right ought to be, a free and independent ſtate; and for the purpoſe of maintaining regular government in the ſame, they made a ſolemn declaration of their rights, and ratified a conſtitution, which is well known.

The ſouth part of the territory of Vermont was formerly claimed by Maſſachuſetts. As early as the year 1718, that government had granted forty-nine thouſand acres, comprehending part of the preſent towns of Brattleborough, Fulton and Putney, as an equivalent to the colony of Connecticut, for ſome lands which had been granted by Maſſachuſetts within the limits of the Connecticut charter. In the year 1725, the government of Maſſachuſetts erected a fort in the town of Brattleborough. Around this fort were begun the firſt ſettlements within the preſent limits of Vermont. On a final ſettlement of a diſpute between Maſſachuſetts and New-Hampſhire, the preſent juriſdictional line between Vermont and Maſſachuſetts, was run and eſtabliſhed, in the year 1741. From that time until the year 1764, this territory was conſidered as lying within the juriſdiction of New Hampſhire. During this period, numerous grants were made; and, after the year 1760, ſome conſiderable ſettlements were begun under the authority of that province. In the year 1764, by order of the king of Britain, this territory was annexed to the province of New York. The government of that province pretended to claim the right of ſoil, as well as juriſdiction, and held the grants formerly made under New Hampſhire, to be void. This occaſioned a long ſeries of altercation between the ſettlers and claimants under New Hampſhire and the government of New York, and which, at the commencement of the late revolution, terminated in the eſtabliſhment of a ſeparate juriſdiction in the preſent ſtate of Vermont. A particular detail of this controverſy would be unentertaining. It is ſufficient to obſerve, that on the 17th day of October, 1790, the diſpute was finally compromiſed, by commiſſioners appointed by the ſtates of New York and Vermont; and the claims of New York, both to juriſdiction and property, extinguiſhed, in conſideration of the ſum of thirty thouſand dollars to be paid by the ſtate of Vermont to that of New York; and on the 4th of March, 1791, Vermont was admitted a member of the federal union. In the late war, between Britain and the United States, the inhabitants of this territory took a very early and active part. Immediately on the news of the battle of Lexington, a company of Volunteers, under the late general Ethan Allen, attacked and took the Britiſh garriſon of Crown Point and Ticonderoga. A regiment was commiſſioned by Congreſs and continued in ſervice under the command of the late colonel Warner. Other troops were raiſed and conſtantly kept in ſervice by the convention of New Hampſhire grants, and afterwards by the ſtate of Vermont. The ſpirit of theſe

Verm

these troops, and the militia of the grants, in the battle of Hubberton and Bennington, in the year 1777, and the assistance which they afforded in the capture of Burgoyne, are well known to the public. General Burgoyne in a letter to the British ministry, written at Saratoga, makes the following observation: "The inhabitants of the New Hampshire grants, a territory unpeopled and almost unknown in the last war, now pour forth by thousands, and hang like dark clouds on my left."—*Morse.*

VERNON, a place in Sussex county, New-Jersey, east of the source of Wall Kill, and about 21 miles N. E. of Newtown.—*ib.*

VERRETTES, a settlement in the French part of the Island of St Domingo, on the S. W. bank of Artibonite river; 4 miles S. by E. of the settlement of Petit Riviere.—*ib.*

VERSAILLES, the chief town of Woodford county, Kentucky; situated on a small stream which falls into Kentucky river. It contains a court-house, stone gaol, and about 30 houses, and lies 13 miles W. by S. of Lexington.—*ib.*

VERSHIRE, a township of Vermont, Orange county, adjoining Fairlee, and containing 439 inhabitants.—*ib.*

VERT *Bay*, or *Green Bay*, in the Straits of Northumberland, in N. America, opens to the N. E. opposite St John's island. The head of the bay approximates within 12 miles of the north-easternmost branch of the Bay of Fundy. It is about 10 leagues to the N. W. of Tatamagauche Harbour, and serves in part to separate the British provinces of Nova-Scotia and New-Brunswick.—*ib.*

VESPA (See *Encycl.*). A new species of this genus of insects has been lately described by *Cuvier*, in a note read before the Philomathic Society of Paris. It has some resemblance to the *vespa nidulans* of Fabricius, which, as is generally known, is a native of certain parts of America. The nests of the vespa nidulans are constructed of a very fine web, of a very solid and pretty white paste. Their form is that of a bell closed upon all sides, excepting a narrow hole at the bottom; and they are suspended from the branches of trees.

The *vespa* described by Cuvier, which is a native of Cayenne in America, has in general more volume than the preceding species, and its paste is grey, coarser, less homogeneous, and less solid. The bottom of its nest also, in lieu of being shaped funnel-like, is flat, and the orifice appears at one of the sides of the bottom part, and not in the middle. In the country where it is found, this species of wasp is called the *tatou fly* (*mouche tatou*). It differs greatly in form from that which Fabricius has described; it is all entirely of a shining black; the first articulation, or joint of its abdomen, is narrow, and in form of a pear; the second, larger than the others, is in form of a bell: the wings are brown. The following is the character assigned to it by Cuvier:

Vespatatua, Nigra, Nitida, Alis fuscis, abdomine pedicellato.

VESPERTILIO (see *Encycl.*) has been subjected to some cruel, but curious experiments, by the Abbé Spallanzani and M. de Jurine. The former of these philosophers having let loose several bats in a chamber perfectly dark, found that they flew about in it without any impediment, neither rushing against any thing in the apartment, nor touching the walls with their wings. This surprised him; but imagining that they were conducted by some glimpse of light which he did not perceive, he blindfolded them with a small and very close hood. They then ceased to fly; but he observed, at the same time, that this did not proceed from any deprivation of light, but rather from the constraint thence occasioned, especially when a hood of a very light texture was attended with the same effect.

He then conceived the idea of pasting up the eyes of the bats with a few drops of size or gum; but they still flew about in the same manner as if their eyes had been open. As this, however, was not sufficient, he pasted up the eyes of these animals with round bits of leather; and this even did not impede them in their flight.

That he might at length be certain of his object, he blinded them entirely, either by burning the cornea with a red hot wire, or by pulling out the pupil with a pair of small pincers, and scooping out the eye entirely. Not contented even with this precaution, he covered the wounds with pieces of leather, that the light might have no influence whatever on the remains of the organs which had been destroyed. The animals seemed to suffer very much by this cruel operation; but when they were compelled to use their wings, either by day or by night, and even in an apartment totally dark, they flew perfectly well, and with great caution, towards the walls, in order to suspend themselves when they wished to rest. They avoided every impediment, great or small, and flew from one apartment to another, backwards and forwards, through the door by which they were connected, without touching the frame with their wings. In a word, they shewed themselves as bold and lively in their flight as any other animals of the same species which enjoy the use of their eye-sight.

These experiments were repeated by M. Jurine, and with the same results. Spallanzani had supposed that the bat possessed some organ or sense which is wanting in the human species, and which supplies to these animals the place of vision; and Jurine determined to ascertain the truth or falsehood of this hypothesis by anatomical researches. During the course of these, he found the organ of hearing very great in proportion to that of other animals, and a considerable nervous apparatus assigned to that part. The upper jaw also is furnished with very large nerves, which are expanded in a tissue on the muzzle.

M. Jurine then extended his experiments to the organ of hearing and that of smell. Having put a small hood on a long eared bat, it immediately pulled it off, and flew. He stopped up its ears with cotton; but it freed itself in the like manner from that inconvenience. He then put into its ears a mastic of turpentine and wax. During the operation the animal shewed a great deal of impatience, and flew afterwards very imperfectly.

A long-eared bat, the ears of which had been bound up, flew very badly: but this did not arise from any pain occasioned by the ligature; for when its ears were sewed up, it flew exceedingly well. In all probability the animal would have preferred having its ears bound up to having them sewed. Sometimes it flew towards the cieling, extending its muzzle before it settled.

M. Jurine poured liquid pomatum into the ears of a bat which enjoyed the use of its sight. It appeared to be much affected by this operation; but when the subftance was removed it took flight. Its ears were again filled, and its eyes were taken out; but it flew then only in an irregular manner, without any certain or fixed direction.

The ears of a horfe-fhoe bat, which had the ufe of its fight, were filled with tinder mixed with water. It was uneafy under the operation, and appeared afterwards reftlefs and ftunned; but it conducted itfelf tolerably well. On being blinded, it rufhed with its head againft the ceiling, and made the air refound with ftrokes which it gave itfelf on the muzzle. This experiment was repeated on other bats with the like effects.

The tympanum of a large horfe-fhoe bat was pierced with a pin (*trois quart*). The animal appeared to fuffer much from the operation, and fell down in a perpendicular direction when thrown into the air. It died next morning. The fame effect was produced on piercing the tympanum of a long-eared bat with a needle.

The author then made very accurate refearches on the difference between the organifation of the brain of thefe two kinds of bats; and, after a careful diffection, found that the eye of the long-eared bat is much larger than that of the horfe-fhoe bat, but that the optic nerve is proportioned to it. The outer part of the ear of the former is much larger than that of the latter, but the interior part is fmaller.

The horfe-fhoe bat is indemnified for this difference by a greater extenfion of the organ of fmell, as evidently appears when the external elevations and irregularities of its muzzle are examined. When it is about to take flight, it agitates its nofe much more than the long-eared bat.

From thefe experiments, the author concludes: *Firft*, That the eyes of the bat are not indifpenfably neceffary to it for finding its way; *fecondly*, That the organ of hearing appears to fupply that of fight in the difcovery of bodies, and to furnifh thefe animals with different fenfations to direct their flight, and enable them to avoid thofe obftacles which may prefent themfelves.

VESSEL *Bay*, on the eaft fhore of Lake Champlain, fets up to the N. E. in the townfhip of Charlotte, in Vermont.—*Morse.*

VIBRATION Figures, are certain figures formed by fand or very dry faw-duft, on a vibrating furface, which is connected with the fenfation of found in our organs of hearing. If the furface, on which the figures are to be formed, be ftrewed over with bodies eafily put in motion, thefe, during the vibration, remain on the parts at reft, and are thrown from the parts in motion. The form of the parts at reft, which will be fhewn by the fand that remains unmoved, and which, in general, is fymmetric, is called a *vibration figure*. To produce fuch a figure, nothing is neceffary but to know the method of bringing that part of the furface which you wifh not to vibrate into a ftate of reft, and of putting in motion that which you wifh to vibrate. On this depends the whole expertnefs of producing vibration figures.

Thus take a fquare piece of glafs, pretty thin, and very fmooth, fuch as that ufed for windows, about four or five inches over, or even more. Smooth it at the edges on a grinding-ftone; ftrew a little faw-duft over its furface, and lay hold of it gently with the thumb and fore-finger of the left hand. Holding it thus by the middle, with the right hand rub a violin bow foftly againft one of its edges, drawing the bow either up or down in a direction almoft perpendicular to the furface of the glafs, and you will fee a tremulous movement, and the whole duft leap about. If the bow be exactly in the middle of one of the fides, the duft will arrange itfelf almoft in the direction of the two diagonals, dividing the fquare into four ifofceles triangles. If the bow be applied at a quarter only of the diftance of the one corner from the other, the duft will arrange itfelf in fuch a manner as to be found in the two diameters of the fquare, dividing it into four equal fquares. At other times, when the bow deviates a little, the duft forms a figure like a double C, when the two letters are joined back to back. If the fquare be held by the two extremities of the diameter oppofite to that againft which the bow is applied, the duft will form a kind of oval, one of the axes of which will be the fame diameter. If the glafs be of a circular figure, and be held by the middle, the duft will arrange itfelf in fuch a manner as to form the fix radii of a regular hexagon. Thefe difcoveries were made by Dr Chladni, about the time that he invented the mufical inftrument, to which he gave the name of EUPHON (fee that article, *Suppl.*); and as he found the vibration figures to vary in form with the various tones produced by the vibrating fubftances, a profecution of his experiments may probably contribute to throw new light on the philofophy of mufical founds. We fhall therefore give, from the 3d volume of *Neues Journal der Phyfik*, by Profeffor Gren, a few directions for making fuch experiments.

Any fort of glafs may be employed, provided its furface be fmooth; and when the plate has acquired the proper vibration, it fhould be kept in that ftate for fome feconds, by continuing to rub it with the bow. The figures will thus be accurately formed.

Such plates fhould be procured as are pretty equal in thicknefs. It may be faid, in general, that a plate the thinner it is will be fo much the fitter for thefe experiments, though in this refpect there is a certain minimum. In fmall plates, fuch as thofe that are circular, and not above fix inches in diameter, the obfervation is general; but in larger plates too great thinnefs is prejudicial. Befides, it will be found that very thin glafs is commonly very uneven, and muft therefore be unfit for the experiments.

In practifing the experiments, it will be proper to have plates of different fizes; and the fand employed fhould not be too fine. In other words, it muft be of fuch a nature that when you incline the glafs-plate it may readily roll off; becaufe, in that cafe, it will be eafily thrown from the vibrating parts. It will be of advantage that it be mixed with fine duft, which fhews peculiar phenomena during the experiments, as it collects itfelf at one place of the vibrating part.

The plate muft be equally beftrewed with fand, and not too thick, as the lines will then be exceedingly fine, and the figures will acquire a better defined appearance.

VICIOSAS *Iflas*, ifles of the Bay of Honda, on the coaft of Honduras, or the Spanifh Main.—*Morse.*

VICTORIA, an ifland on the coaft of Brazil, eaftward of St Sebaftian's Ifland.—*ib.*

VICTORY, *Cape*, is the extreme N. W. point of the ftraits of Magellan, at the opening to the S. Pacific Ocean. S. lat. 52 15, W. long. 76 40.—*ib.*

Victory, a townſhip of Vermont, ſituated in Eſſex county, and bounded eaſt by Guildhall, on Connecticut river.—*ib.*

VIENNA, a port of entry and poſt-town of the eaſtern ſhore of Maryland, Dorcheſter county, on the weſt ſide of Nanticoke river, about 15 miles from its mouth. It contains about 30 houſes, but carries on a briſk trade with the neighbouring ſea-ports, in lumber, corn, wheat, &c. Its foreign exports in 1794, amounted to 1,667 dollars. It is 15 miles N. W. of Saliſbury, 32 S. S. E. of Eaſton, and 150 S. S. W. of Philadelphia.—*ib.*

Vienna, the capital of Greene county, Kentucky; ſituated on the north ſide of Green river, about 158 miles W. S. W. of Lexington.—*ib.*

VIETA (Francis), a very celebrated French mathematician, was born in 1540 at Fontenai, or Fontenai-le-Comté, in Lower Poitou, a province of France He was Maſter of requeſts at Paris, where he died in 1603, being the 63d year of his age. Among other branches of learning in which he excelled, he was one of the moſt reſpectable mathematicians of the 16th century, or indeed of any age. His writings abound with marks of great originality, and the fineſt genius as well as intenſe application. His application was ſuch, that he has ſometimes remained in his ſtudy for three days together without eating or ſleeping. His inventions and improvements in all parts of the mathematics were very conſiderable. He was in a manner the inventor and introducer of Specious Algebra, in which letters are uſed inſtead of numbers, as well as of many beautiful theorems in that ſcience. He made alſo conſiderable improvements in geometry and trigonometry. His angular ſections are a very ingenious and maſterly performance: by theſe he was enabled to reſolve the problem of Adrian Romanus, propoſed to all mathematicians, amounting to an equation of the 45th degree. Romanus was ſo ſtruck with his ſagacity, that he immediately quitted his reſidence of Wirtzbourg in Franconia, and came to France to viſit him, and ſolicit his friendſhip. His Apollonius Gallus, being a reſtoration of Apollonius's tract on Tangencies, and many other geometrical pieces to be found in his works, ſhew the fineſt taſte and genius for true geometrical ſpeculations.—He gave ſome maſterly tracts on Trigonometry both plane and ſpherical, which may be found in the collection of his works, publiſhed at Leyden in 1646, by Schooten, beſides another large and ſeparate volume in folio, publiſhed in the author's life-time, at Paris, in 1579, containing extenſive trigonometrical tables, with the conſtruction and uſe of the ſame, which are particularly deſcribed in the introduction to Dr Hutton's Logarithms, p. 4. &c. To this complete treatiſe on trigonometry, plane and ſpherical, are ſubjoined ſeveral miſcellaneous problems and obſervations; ſuch as, the quadrature of the circle, the duplication of the cube, &c. Computations are here given of the ratio of the diameter of a circle to the circumference, and of the length of the ſine of 1 minute, both to a great many places of figures; by which he found that the ſine of 1 minute is

between 2908881959
and 2908882056;

alſo the diameter of a circle being 1000, &c. that the perimeter of the inſcribed and circumſcribed polygon of 393216 ſides will be as follows, viz. the

perim. of the inſcribed polygon - 31415926535
perim. of the circumſcribed polygon 31415926537

and that therefore the circumference of the circle lies between thoſe two numbers.

Vieta having obſerved that there were many faults in the Gregorian Kalendar, as it then exiſted, compoſed a new form of it, to which he added perpetual canons, and an explication of it, with remarks, and objections againſt Clavius, whom he accuſed of having deformed the true Lelian reformation, by not rightly underſtanding it.

Beſides theſe, it ſeems a work, greatly eſteemed, and the loſs of which cannot be ſufficiently deplored, was his *Harmonicon Cœleſte*, which being communicated to father Merſenne, was, by ſome perfidious acquaintance of that honeſt minded perſon, ſurreptitiouſly taken from him and irrecoverably loſt, or ſuppreſſed, to the great detriment of the learned world. There were alſo, it is ſaid, other works of an aſtronomical kind, that have been buried in the ruins of time.

Vieta was alſo a profound decipherer, an accompliſhment that proved very uſeful to his country. As the different parts of the Spaniſh monarchy lay very diſtant from one another, when they had occaſion to communicate any ſecret deſigns, they wrote them in ciphers and unknown characters during the diſorders of the league. The cipher was compoſed of more than 500 different characters which yielded their hidden contents to the penetrating genius of Vieta alone. His ſkill ſo diſconcerted the Spaniſh councils for two years, that they publiſhed it at Rome, and other parts of Europe, that the French king had only diſcovered their ciphers by means of magic.

VILLA *de Moſc*, a town in the province of Tabaſco, 4 leagues from the town of Eſtape, on Tabaſco river.—*Morse.*

Villa *Hermoſo*, a town of Mexico or New-Spain, near the mouth of a river which falls into the Bay of Campeachy, and Gulf of Mexico.—*ib.*

Villa *Nooa*, in Brazil, about 120 miles weſt of Porto Seguro, and as far S. E. by S. of Carloſa.—*ib.*

Villa *Rica*, or *Almeria*, a town of Tlaſcala or New-Spain, in N. America. It ſtands on the coaſt on a ſmall river, having an indifferent port, but in a better air than Vera Cruz, 20 leagues north of the latter. A clandeſtine trade is carried on here between ſome of the Spaniſh merchants on the ſhore, and French of St Domingo and Martinique.—*ib.*

VILLIA, *La*, a town and river of Veragua and Guatimala audience, in New-Spain. It is about 7 leagues from Nata, bordering on Panama. The river is very large, and at low water breaks at the mouth as on a flat ſhore; ſo that large ſhips anchor within cannon ſhot, but barks of about 40 tons may go up about a league and a half. The harbour is a quarter of a league above the town. About a league to the windward, is a large rock, generally covered with vaſt numbers of wild fowl.—*ib.*

VINALHAVEN, a townſhip on the coaſt of the Diſtrict of Maine, in Hancock county, containing 578 inhabitants. It is ſouth-eaſt of Deer Iſland, and 250 miles from Boſton.—*ib.*

VINCENTS,

VINCENTS, *Fort*, in the N. W. Territory, ftands on the eaft fide of Wabafh river, 150 miles from its mouth. It was erected in the year 1787, in order to repel the incurfions of the Wabafh Indians, and to fecure the weftern lands from intruding fettlers. It has four fmall brafs cannon, and is garrifoned by a Major and 2 companies. The town of Vincents contained, in 1792, about 1,500 fouls, principally of French extraction. It is 300 miles S. W. of Fort Recovery. N. lat. 39 15, W. long. 90 7. They raife Indian corn, and wheat; and tobacco of an extraordinary good quality; fuperior, it is faid, to that produced in Virginia. They have a fine breed of horfes, brought originally by the Indians from the Spanifh fettlements, on the weftern fide of the Miffiflippi. Here are large herds of fwine, and black cattle, and the fettlers deal with the Indians for furs and deer-fkins. Hemp of a good quality grows fpontaneoufly in the low lands of the Wabafh; as do grapes, of which the inhabitants make a fufficient quantity, for their own confumption, of well tafted red wine. Hops, large and good, are found in many places, and the lands are particularly adapted to the culture of rice. All European fruits thrive well both here, and in the country bordering on the river Ohio.—*ib.*

VINCENT, *St*, one of the 14 captainfhips of Brazil, in S. America, and the moft foutherly one. The capital is an inconfiderable place, with only about 60 houfes, and the harbour will not receive large veffels. It has 5 or 6 fugar-mills, and lies 76 leagues fouth-weft of Rio Janeiro. S. lat. 23 40, W. long. 45 10.—*ib.*

VINCENT, *St*, a town on the coaft of Brazil; fituated on Amiaz Ifland, in the Bay of All Saints or Sanctos; in which ifland is the city of Dos Sanctos, the ifland lying on the weft fide of the entrance into the ifland. S. lat. 24 15, W. long. 46 30.—*ib.*

VINCENT, *de la Pazes, St*, or *Onda*, a town of Popayan and Terra Firma, in S. America; about 25 miles eaftward of San Sebaftian, with a port where canoes from Carthagena and St Martha unload their merchandize. —*ib.*

VINCENT, a townfhip of Pennfylvania, fituated in Chefter county.—*ib.*

VINCENT, *Port St*, on the coaft of Chili, in the S. Pacific Ocean, is 6 miles N. N. E. of the mouth of the river Biobio, having a fafe harbour and fecure againft all winds but the weft, which blows right in. Talcaguama Port is 6 miles to the northward of it.—*ib.*

VINCENTO, a channel which goes in on the weft fide of the channel of Amiaz Ifland, in the Bay of All Saints, on the coaft of Brazil.—*ib.*

VINER'S *Ifland*, in Hudfon's Bay, lies N. E. of the mouth of Albany river.—*ib.*

VINEYARD, *New*, a plantation in Lincoln county, Diftrict of Maine, on the two north-eafternmoft branches of Sandy river, about 59 miles N. by W. of Brunfwick, and 37 N. W. of Hallowell.—*ib.*

VINEYARD *Sound*, on the fouth-eaftern coaft of Maffachufetts, is the ftrait or paffage between the Elizabeth Iflands and Martha's Vineyard. The S. W. channel of which, about 7 miles broad, has Gay Head on the S. E. and the Sow and Pigs on the N. W.—*ib.*

VINTAIN, a town fituated about two miles up a creek on the fouthern fide of the river Gambia. It is much reforted to by Europeans, on account of the great quantities of bees-wax which are brought hither for fale. The wax is collected in the woods by the Feloops, a wild and unfociable race of people. Their country, which is of confiderable extent, abounds in rice; and the natives fupply the traders, both on the Gambia and Caffamanfa rivers, with that article, and alfo with goats and poultry, on very reafonable terms. The honey which they collect is chiefly ufed by themfeves in making a ftrong intoxicating liquor, much the fame as the mead which is produced from honey in Great Britain.

In their traffic with Europeans, the Feloops generally employ a factor, or agent, of the Mandingo nation, who fpeaks a little Englifh, and is acquainted with the trade of the river. This broker makes the bargain; and, with the connivance of the European, receives a certain part only of the payment; which he gives to his employer as the whole; the remainder (which is very truly called the *cheating money*) he receives when the Feloop is gone, and appropriates to himfelf as a reward for his trouble. Vintain, according to Mr Park, from whofe valuable travels this account of the Feloops is taken, is fituated in 13° 9′ North Lat. and 15° 56′ Long. Weft from Greenwich.

VIPER *Key*, one of the Tortugas, on the coaft of Florida; 5 miles N. eaftward of Duck Key, and 3½ E. of Old Matacombe.—*Morfe.*

VIRGIL, a military townfhip of Onondago county, New-York, having Dryden on the W. Cincinnatus E. Homer N. and on the S. 230,000 acres of land on Sufquehannah river, ceded to the State of Maffachufetts. It is under the jurifdiction of Homer, which was incorporated in 1794.—*ib.*

VIRGIN GORDA, one of the principal of the Virgin Ifles, in the Weft-Indies. It lies 4 leagues to the E. of Tortula, and of a very irregular fhape. Its greateft length from E. to W. is about 18 miles; is worfe watered than Tortula, and has fewer inhabitants. A mountain which rifes in the centre, is affirmed to contain a filver mine. N. lat. 18 18, W. long. 64.—*ib.*

VIRGIN *Iflands*, a group of fmall iflands in the Weft-Indies, to the eaftward of the ifland of Porto Rico, belonging to different European powers. They extend for the fpace of 24 leagues, from E. to W. and about 16 leagues from N. to S. and nearly approach the eaft coaft of Porto Rico. They are every way dangerous to navigators, though there is a bafon in the midft of them of 6 or 7 leagues in length, and 3 or 4 in breadth, in which fhips may anchor and be fheltered and land-locked from all winds; which is named the Bay of Sir Francis Drake, from his having paffed through them to St Domingo. Thofe which are occupied and inhabited appear under their refpective names; but others are deftitute both of names and inhabitants. The Britifh and Danes poffefs moft of them; but the Spaniards claim thofe near Porto Rico. The ifland of *Virgin Gorda*, on which depend Anegada, Nicker, Prickley Pear, Mofquito Iflands, Camanoes, Dog-Iflands, the Fallen City, the Round Rock, Ginger, Cooper's, Salt, Peter's and Dead Cheft, belong to the *Britifh;* as alfo *Tortola*, on which depend Joft Van Dykes, Little Van Dykes, Guana, Beef, and Thatch Iflands. To the *Danes* belong *St Thomas's Ifland*, on which Brafs, Little Saba, Buck Ifland, Great and Little St James, and Bird Ifland are dependant; with *St John's*, to which depend Lavango, Cam, and Witch Iflands; and they have alfo Santa Ifland, or St Croix.

The

The *Spaniards* claim Serpent's Island, (called by the British Green Island) the Tropic Keys, Great and Little Passage Island, and particularly Crab Island. The Booby birds are so tame on Bird Island, that a man, it is said, in a short time, may catch sufficient in his hand to supply a fleet. These islands lie about lat. 18 20 N. and the course through them, with due attention, is perfectly safe at west by N. and west north west as far as the west end of the fourth island. Leave this on the starboard side, and the island called Foul Cliff, on the larboard, between which there is 16 fathoms, and a free channel to the westward, before there is any alteration of the course; for though there be but six or seven fathoms in some places, it is no where shoaler, and in some places there is from 16 to 20 fathoms. The island of Anguilla, on the north side of St Martin's Island, is E. S. E. from them.—*ib.*

VIRGINITY, the test or criterion of a virgin; or that which intitles her to the denomination. See HYMEN, *Encycl.*

VIRGIN MARY *Cape*, the N. E. point of the entrance of the straits of Magellan, in the S. Atlantic Ocean, is a steep white cliff. S. lat. 52 32, W. long. 67 54. The variation of the compass, in 1780, was 24 30, E.—*Morse.*

VIRGIN *Rocks*, off the S. E. part of the coast of Newfoundland Island, 20 leagues S. E. of Cape Race. N. lat. 46, according to others, lat. 46 30, and these last say 17 or 18 leagues S. E. by E. of Cape Ballard. —*ib.*

VISION. In the article OPTICS, n° 154. (*Encycl.*), it is said, that as we have a power of contracting or relaxing the *ligamenta ciliaria*, and thereby altering the form of the crystalline humour of the eye, we hence see objects distinctly at different distances. It appears, however, from some experiments made by Mr Everard Home and Mr Ramsden, in the year 1794, that this power of contracting and relaxing the ligamenta ciliaria is not alone sufficient to account for the phenomenon. Conversing with Mr Home on the different uses of the chrystalline humour, Mr Ramsden said, that as that humour "consists of a substance of different densities, the central parts being the most compact, and from thence diminishing in density gradually in every direction, approaching the vitreous humour on one side, and the aqueous humour on the other, its refractive power becomes nearly the same with that of the two contiguous substances. That some philosophers have stated the use of the chrystalline humour to be, for accommodating the eye to see objects at different distances; but the firmness of the central part, and the very small difference between its refractive power near the circumference and that of the vitreous or the aqueous humour, seemed to render it unfit for that purpose; its principal use rather appearing to be for correcting the aberration arising from the spherical figure of the cornea, where the principal part of the refraction takes place, producing the same effect that, in an achromatic object-glass, we obtain in a less perfect manner by proportioning the radii of curvature of the different lenses. In the eye the correction seems perfect, which in the object-glass can only be an approximation; the contrary aberrations of the lenses not having the same ratio: so that, if this aberration be perfectly corrected, at any given distance from the centre, in every other it must be in some degree imperfect.

"Pursuing the same comparison: In the achromatic object-glass we may conceive how much an object must appear fainter from the great quantity of light lost by reflection at the surfaces of the different lenses, there being as many primary reflections as there are surfaces; and it would be fortunate if this reflected light was totally lost. Part of it is again reflected towards the eye by the interior surfaces of the lenses; which, by diluting the image formed in the focus of the object glass, makes that image appear far less bright than it would otherwise have done, producing that milky appearance so often complained of in viewing lucid objects through this sort of telescope.

"In the eye, the same properties that obviate this defect, serve also to correct the errors from the spherical figure, by a regular diminution of density, from the centre of the crystalline outward. Every appearance shews the crystalline to consist of laminæ of different densities; and if we examine the junction of different media, having a very small difference of refraction, we shall find that we may have a sensible refraction without reflection. Now, if the difference between the contiguous media in the eye, or the laminæ in the crystalline, be very small, we shall have refraction without having reflection: and this appears to be the state of the eye; for although we have two surfaces of the aqueous, two of the crystalline, and two of the vitreous humour, yet we have only one reflected image; and that being from the anterior surface of the cornea, there can be no surface to reflect it back, and dilute an image on the retina.

"This hypothesis may be put to the test whenever accident shall furnish us with a subject having the crystalline extracted from one eye, the other remaining perfect in its natural state; at the same time we may ascertain whether or no the crystalline is that part of the organ which serves for viewing objects at different distances distinctly. Seeing no reflection at the surface of the crystalline, might lead some persons to infer that its refractive power is very inconsiderable; but many circumstances shew the contrary; yet what it really is may be readily ascertained by having the focal length and distance of a lens from the operated eye, that enables it to see objects the most distinctly; also the focal length of a lens, and its distance from the perfect eye, that enables it to see objects at the same distance as the imperfect eye: these data will be sufficient whereby to calculate the refractive power of the crystalline with considerable precision.

"Again, having the spherical aberration of the different humours of the eye, and having ascertained the refractive power of the crystalline, we have data from whence to determine the proportional increase of its density as it approaches the central part, on a supposition that this property corrects the aberration.

"An opportunity presented itself for bringing the observations of Mr Ramsden, respecting the use of the crystalline lens, to the proof. A young man came into St George's Hospital with a cataract in the right eye. The crystalline lens was readily extracted, and the union of the wound in the cornea took place unattended by inflammation; so that the eye suffered the smallest

smallest degree of injury that can attend so severe an operation. The man himself was in health, 21 years of age, intelligent, and his left eye perfect: the other had been an uncommonly short time in a diseased state, and 27 days after the operation appeared to be free from every other defect but the loss of the crystalline lens.

"A number of experiments were made on the imperfect eye, assisted by a lens, and compared with the perfect eye. The aim of these trials, which were judiciously varied, was to ascertain whether the eye which had been deprived of the crystalline lens was capable of adjusting itself to distinct vision at different distances. Among other results, the perfect eye, with a glass of $6\frac{1}{2}$ inches focus, had distinct vision at 3 inches; the near limit was $1\frac{7}{8}$ inch, the distant limit less than 7 inches. The imperfect eye, with a glass $2\frac{2}{10}$ inches focus, with an aperture $\frac{3}{20}$ths of an inch, had distinct vision at $2\frac{7}{8}$ inches, the near limit $1\frac{7}{8}$ inch, and the distant limit 7 inches. The accuracy with which the eye was brought to the same point, on repeating the experiment, proved it to be uncommonly correct; and as he did not himself see the scale used for admeasurement, there could be no source of fallacy. From the result of this experiment, it appears that the range of adjustment of the imperfect eye, when the two eyes were made to see at nearly the same focal distance, exceeded that of the perfect eye. Mr Ramsden suggested a reason why the point of distinct vision of the imperfect eye might appear to the man himself nearer than it was in reality; namely, that from the imperfection of this organ he might find it easier to read the letters when they subtended a greater angle than at his real point of distinct vision. The experiments, however, appear to shew that the internal power of the eye, by which it is adjusted to see at different distances, does not reside in the crystalline lens, at least not altogether; and that if any agency in this respect can be proved to reside in the crystalline, the other powers, whatever they may be, are capable of exertion beyond their usual limits, so as to perform its office in this respect.

"From these considerations, and in consequence of other reflections tending to shew that an elongation of the optical axis is not probably the means of adjustment, these philosophers directed their enquiries to ascertain how far the curvature of the cornea might be subject to change. They found by trial that this part of the organ possesses a degree of elasticity which is very considerable, both for its perfection and its range; and by anatomical dissection it was found that the four straight muscles of the eye do in effect terminate in the cornea at their tendinous extremities; that the whole external lamina of the cornea could by gentle force be separated, by means of these muscles, from the eye; so that the tendons seem lost in the cornea, and this last has the appearance of a central tendon. It was also seen that the central part of the cornea is the thickest and the most elastic.

"These were considerable advances towards establishing the hypothesis of adjustment by the external curve of the eye. It remained to be shewn, by experiments on the living subject, that this curve does really vary in the due direction, when the mind perceives the distinct visible sensation of objects at different distances. For this purpose Mr Ramsden provided an apparatus, consisting of a thick board steadily fixed, in which was a square hole large enough to admit a person's face; the forehead and chin resting against the upper and lower bars, and the cheek against either of the sides; so that when the face was protruded, the head was steadily fixed by resting on three sides; and in this position the left eye projected beyond the outer surface of the board. A microscope, properly mounted, so as with ease to be set in every requisite position, was applied to view the cornea with a magnifying power of thirty times. In this situation, the person whose eye was the object of experiment was desired to look at the corner of a chimney, at the distance of 235 yards, through a small hole in a brass plate, fixed for that purpose, and afterwards to look at the edge of the hole itself, which was only six inches distant. After some management and caution, which the delicate nature of these experiments requires, the motion of the cornea, which was immediately perceptible, became very distinct and certain. The circular section of its surface remained in a line with the wire in the field of the microscope, when the eye was adjusted to the distant object, but projected considerably beyond it when adapted to the near one. When the distant object was only 90 feet from the observer, and the near object six inches, the difference in the prominence of the cornea was estimated at 1-800th of an inch. These experiments were repeated and varied at different times and on different subjects. The observer at the microscope found no difficulty in determining, from the appearance of the cornea, whether the eye was fixed on the remote or the near object.

"From these different experiments Mr Home considers the following facts to have been ascertained:

"1. That the eye has a power of adjusting itself to different distances when deprived of the crystalline lens; and therefore the fibrous and laminated structure of that lens is not intended to alter its form, but to prevent reflections in the passage of the rays through the surfaces of media of different densities, and to correct spherical aberration.

"2. That the cornea is made up of laminæ; that it is elastic, and when stretched is capable of being elongated 1-11th part of its diameter, contracting to its former length immediately upon being left to itself.

"3. That the tendons of the four straight muscles of the eye are continued on to the edge of the cornea, and terminate, or are inserted, in its external laminæ: their action will therefore extend to the edge of the cornea.

"4. That in changing the focus of the eye from seeing with parallel rays to a near distance, there is a visible alteration produced in the figure of the cornea, rendering it more convex; and when the eye is again adapted to parallel rays, the alteration by which the cornea is brought back to its former state is equally visible."

Mr Home made many other experiments with a view to throw light upon this curious subject; and the result of the whole appears to be, that the adjustment of the eye is produced by three different changes in that organ; an increase of curvature in the cornea, an elongation of the axis of vision, and a motion of the crystalline lens. These changes, in a great measure, depend upon the contraction of the four straight muscles of the eye.

eye. Mr Ramfden, from computations grounded on the principles of optics and general ftate of the facts, eftimates that the increafe of curvature of the cornea may be capable of producing one-third of the effect, and that the change of place of the lens, and elongation of the axis of vifion, fufficiently account for the other two-thirds of the quantity of adjuftment neceffary to make up the whole.

The following obfervations on Vifion by Doctor David Hofack of New-York, were read before the Royal Society, May 1, 1794, and the author has politely permitted their infertion in this work.

"By what power is the eye enabled to view objects diftinctly at different diftances? As the pupil is enlarged or diminifhed according to the greater or lefs quantity of light, and in a certain degree to the diftance of the object, it would readily occur that thefe different changes of the pupil would account for the phænomena in queftion. Accordingly anatomifts and philofophers, who have written upon this fubject, have generally had recourfe to this explanation.

"Amufing myfelf with thefe changes of the pupil, as a matter of curiofity, by prefenting to the eye different objects at different diftances, I foon perceived that its contraction and dilatation were irregular and more limited than had been fuppofed; *i. e.* that approaching the object nearer the eye, within a certain diftance, the pupil not only ceafed to contract, but became again dilated; and that beyond a few yards diftance, it alfo ceafed to dilate: thefe circumftances immediately occurred as objections to the above explanation; for were it from the contraction and dilatation of the iris alone that we fee objects at different diftances, I naturally concluded it fhould operate regularly to produce its effects; but if to view an object at a few yards diftance it be enlarged to the utmoft extent, furely it muft of itfelf be infufficient to view one at the diftance of feveral miles; for example, the heavenly bodies.

"Another difficulty here prefents itfelf: in viewing the fun, inftead of dilating, according to the diftance, it contracts, obeying rather the quantity or intenfity of the light, than the diftance of the object. Knowing no other obvious power in the eye itfelf of adapting it to the different diftances of objects, it occurred to me to inquire, whether the combined action of the external mufcles could not have this effect. I firft propofed this query to an optician of eminence in London, and who has written exprefsly on this fubject. I repeated the fame queftion to a celebrated teacher of anatomy. Encouraged by their replies, I have fince attended more particularly to the fubject, and hope my inquiries have not been altogether unfuccefsful. As introductory to a more diftinct view of what I have to advance, it appears neceffary to premife the following obfervations, relative to thofe general laws of vifion which are more particularly connected with this part of the fubject, and to which we fhall have occafion of frequent reference.

"1ft. Let ABC, (plate 3 appendix fig. 1.) be an object placed before the double convex lens DE, at any diftance greater than the radius of the fphere whereof the lens is a fegment; the rays which iffue from the different points of the object, and fall upon the lens, will be fo bent by the refractive power of the glafs as to be made to convene at as many other points behind the lens, and at the place of their concourfe they will form an image or picture of the object. The diftance of the image behind the glafs varies in proportion to the diftance of the object before the glafs; the image approaching as the object recedes, and receding as that approaches. For if we fuppofe, (fig. 2.), A and B two radiating points, from which the rays AC, AD, and BC, BD, fall upon the lens CD, it is manifeft that the rays from the neareft point A diverge more than thofe from the more diftant point B, the angle at A being greater than that of B (A); confequently the rays from A, whofe direction is AE and AF when they pafs through the glafs, muft convene at fome point (as G) more diftant from the lens than the point H, where the lefs diverging rays BK and BL from the point B are made to convene; which may alfo be proved by experiment with the common convex glafs (B).

"It will be neceffary to have this propofition in view, as we fhall afterwards have occafion to ufe it in fhewing, that by varying the diftance between the retina and the anterior part of the eye we are enabled to fee objects at different diftances.

"2d. If an object, as AB, (fig. 3.) be placed at a proper diftance before the eye (E), the rays which fall from the feveral points of the object falling upon the cornea pafs through the pupil, and will be brought together by the refractive power of the different parts of the eye on as many correfponding points of the retina, and there paint the image of the object, in the fame manner as the images of objects placed before a convex lens are painted upon the fpectrum, placed at a proper diftance behind it; thus the rays which flow from the point A are united on the retina at C, and thofe which proceed from B are collected at D, and the rays from all the intermediate points are convened at as many intermediate points of the retina; on this union of the rays at the retina depends diftinct vifion. But fuppofing the eye of a given form, fhould the point of union lie beyond the retina, as muft be the cafe with thofe from the lefs diftant object, agreeable to the preceding propofition; or fhould they be united before they arrive at the retina, as from the more diftant object, it is evident that the picture at the retina muft be extremely confufed. Now as the rays which fall upon the eye from radiating points at different diftances have different degrees of divergence, and the divergence of the rays increafing as the diftance of the radiating point leffens, and, *vice verfa*, leffening as that increafes; again, as thofe rays which have greater degrees of divergence, viz. from the nearer objects, require a ftronger refractive power to bring them together at a given diftance than what is neceffary to make thofe meet which diverge lefs, it is manifeft, that to fee objects diftinctly at different diftances, either the refractive power of the eye muft be increafed or diminifhed, or the diftance between the iris and retina be varied, correfponding with the different diftances of the objects; both

(B) See *Kepler* Diopt. Poftul. *Smith's Optics*, *Gravefande*, &c.

both of which probably take place, as will hereafter appear (c).

"Having then eftablifhed thefe as our premifes, we fhall next examine the different principles which have been employed for explaining vifion at different diftances.

"Moft writers upon this fubject refer this power of the eye to the contraction and dilatation of the iris. Within certain limits this would, upon firft examination, as already obferved, appear to be the cafe, fince the pupil enlarges as the object is further removed from the eye, and again contracts as it is brought near. The extent of this principle I have already pointed out; but I fufpect we alfo err in attributing to the difference of diftance what are only effects of different quantities of light, a circumftance in which it is the more eafy to commit error as they are generally proportionate one to the other; *i. e.* as the object is near we require a lefs degree of light, and to exclude what is fuperfluous the iris contracts; but as it is more diftant, a greater quantity of light becomes neceffary, and the iris dilates: thus far we fee the ufe of the enlargement or diminution of the pupil, as the object is more or lefs diftant. But diftinct vifion does not confift in the quantity of light alone, though too much or too little would obfcure the image.

"It is alfo neceffary that the rays which flow from the object fhould fall upon the retina in a certain direction, to form a diftinct picture; but furely the greater or lefs quantity of light, the greater or lefs number of rays, which it is only the property of the iris to diminifh or increafe, cannot alter the direction.

"But there is ftill another argument to prove, that the contraction or enlargement of the pupil is not of itfelf fufficient to produce diftinct vifion at different diftances, viz. that the myopes, whofe pupil contracts and dilates as in other eyes, are ftill unable to adapt the eye to different diftances; and the means by which this is remedied certainly does not confift in a larger or fmaller aperture for the rays to pafs through, but a power of altering their direction, which the change in the fhape of the eye had rendered too convergent. The fame fact is alfo obfervable in thofe who fquint; the pupil in both eyes equally contracts and dilates, but ftill the vifion of one eye is lefs perfect than the other. Another principle upon which it has been attempted to explain this power of the eye, is a fuppofed change in the convexity of the cryftalline lens; the ancients had fome obfcure notion of it, but it has been lately purfued by Mr Thomas Young, in a paper publifhed in the Philofophical Tranfactions of London for 1793. He has endeavoured to demonftrate the exiftence of mufcles in the cryftalline lens, and by their action to account for diftinct vifion at different diftances. This opinion deferves here the more particular examination, having met the attention of the Royal Society, and thereby likely to influence the general opinion upon this fubject.

"That we may not miftake the meaning of the author, I beg leave to premife his defcription of the ftructure of the lens. 'The cryftalline lens of the ox,' he obferves, 'is an orbicular convex tranfparent body, compofed of a confiderable number of fimilar coats, of which the exterior clofely adhere to the interior; each of thefe coats confifts of fix mufcles, intermixed with a gelatinous fubftance, and attached to fix membranous tendons. Three of thefe tendons are anterior, three pofterior; their length is about two-thirds of the femidiameter of their coat; their arrangement is that of three equal and equidiftant rays meeting in the axis of the cryftalline; one of the anterior is directed towards the outer angle of the eye, and one of the pofterior towards the inner angle; fo that the pofterior are placed oppofite to the middle of the interftices of the anterior, and planes paffing through each of the fix, and through the axis, would mark on either furface fix regular equidiftant rays. The mufcular fibres arife from both fides of each tendon, they diverge till they reach the greateft circumference of the coat, and having paffed it, they again converge till they are attached refpectively to the fides of the neareft tendons of the oppofite furface. The exterior or pofterior portion of the fix, viewed together, exhibits the appearance of three penniformiradiated mufcles.'

"In the firft place, to fay nothing of the tranfparency of mufcles, as an argument againft their exiftence, we muft unavoidably fuppofe, as they have *membranous tendons*, which Mr Young informs us he diftinctly obferved, that thefe tendons cannot poffefs the fame degree of tranfparency and denfity with the bellies of thefe mufcles; that is, they muft poffefs fome degree of opacity, or certainly he could not have pointed out their membranous ftructure, nor even the tendon itfelf, as diftinct from the body of the mufcle; and if they have not the fame denfity, from their fituation, and being of a penniform fhape, muft there not be fome irregularity from the difference in the refraction of thofe rays which pafs through the bellies of thofe mufcles, and thofe again which pafs through their membranous tendons? This ftructure then, of confequence, cannot be well adapted for a body whofe regular fhape and tranfparency are of fo much confequence.

"Again, Mr Young defcribes fix mufcles in each layer; but Leeuwenhoek, whofe authority he admits as accurate, relative to the mufcularity of the lens, is certainly more to be attended to in his obfervation of bodies lefs minute, viz. as to the layers themfelves, in which thefe mufcles are found, and which of courfe are larger, and more eafily obferved; but, with his accuracy of obfervation, he has computed, that there are near 2000 laminæ; and according to Mr Young, fuppofing each layer to contain fix mufcles, we have neceffarily, in all, 12,000 mufcles; the action of which certainly exceeds human comprehenfion. I hope this will not be deemed trifling minutenefs, as it is a neceffary and regular confequence, if we admit their exiftence as defcribed.

"But

(c) "Facile enim intelligitur, quo longius radii adveniunt, eo magis effe parallelos; eo minus ergo differre ab axi, et eo minoribus viribus corneæ et lentis cryftallinæ in focum cogi. Ut enim corpus magis diftat, ita fub minori angulo radii adveniunt. Contra fi corpus confpicuum valde vicinum fuerit, radiorum ab eo advenientium angulus eft major, et adeo magis divergentes in oculum incidunt, et viribus egent refringentibus majoribus omnibus denfioribus."—*Haller*, *Elem. Phyf.* lib. xvi.

" But fecondly, as to the exiftence of thefe mufcles, I cannot avoid expreffing a doubt. With the utmoft accuracy I was capable of, and with the affiftance of the *beft* glaffes, to my difappointment, I cannot bear witnefs to the fame circumftances related by Mr Young, but found the lens perfectly tranfparent; at the fame time, left it might be attributed to the want of habit in looking through glaffes, I beg leave to obferve, that I have been accuftomed to the ufe of them in the examination of the more minute objects of natural hiftory. After failing with the glaffes in the natural vifcid ftate of the lens, I had recourfe to another expedient; I expofed different lenfes before the fire to a moderate degree of heat, by which they became opaque and dry; in this ftate it is eafy to feparate the layers defcribed by Mr Young; but although not fo numerous as noticed by the accurate Leeuwenhoek, ftill they were too numerous to fuppofe each to have contained fix mufcles; for I could have fhewn diftinctly at leaft fifty layers, without the affiftance of a glafs, as was readily granted by thofe to whom I exhibited them.

" But a circumftance which would feem to prove that thefe layers poffefs no diftinct mufcles is, that in this opaque ftate they are not vifible, but confift rather of an almoft infinite number of concentric fibres (if the term be at all appropriate) not divided into particular bundles, but fimilar to as many of the fineft hairs of equal thicknefs, arranged in fimilar order: fee fig. 4, 5, and 6, where the arrangement of the layers and fibres has been painted from the real lens of an ox, and that without the affiftance of a glafs. To obferve this fact, any perfon may try the experiment at pleafure, and witnefs the fame with the naked eye, even feparating many layers and their fibres with the point of a penknife.

" This regular ftructure of layers, and thofe confifting of concentric fibres, is unqueftionably better adapted for the tranfmiffion of the rays of light, than the irregular ftructure of mufcles. It may, perhaps, be urged, that the heat to which I expofed the lens may have changed its ftructure: in anfwer to that I obferve, it was moderate in degree, and regularly applied; of confequence we may prefume, as it appeared uniformly opaque, that every part was alike acted upon; but by boiling the lens, where the heat is, without doubt, regularly applied, we obferve the fame ftructure.

" Thirdly, that it is not from any changes of the lens, and that this is not the moft effential organ in viewing objects at different diftances, we may alfo infer from this undeniable fact, that we can, in a great degree, do without it; as after couching or extraction, by which operations all its parts muft be deftroyed, capfule, ciliary proceffes, mufcles, &c.

" Mr Young afferts, from the authority of Dr Porterfield, that patients, after the operation of couching, have not the power of accommodating the eye to the different diftances of objects; at prefent, I believe the contrary fact is almoft univerfally afferted (D).

" Befides, if the other powers of the eye are infufficient to compenfate for the lofs of this denfe medium, the lens, a glafs of the fame fhape anfwers the purpofe, and which certainly does not act by changing its figure. I grant their vifion is not fo perfect; but we have other circumftances upon which this can be more eafily explained; which will be particularly noticed under the next head. It may not be improper alfo to obferve, that the fpecific gravity of the cryftalline compared with that of the vitreous humour, and of confequence, its denfity and power of refraction, is not fo great as has been generally believed. Dr Bryant Robinfon, by the hydroftatic balance, found it to be nearly as 11 to 10. I have alfo examined them with the inftrument of Mr Schmeiffer, lately prefented to the Royal Society, and found the fame refult; of confequence the cryftalline lens is not fo effentially neceffary for vifion as has been reprefented; efpecially as it is alfo probable, that upon removing it, the place which it occupied is again filled by the vitreous humour, whofe power of refraction is nearly equal. At the fame time we cannot fuppofe the lens an unneceffary organ in the eye, for nature produces nothing in vain; but that it is not of that indifpenfable importance, writers upon optics have taught us to believe.

" Fourthly, Mr Young tells us, he has not yet had an opportunity of examining the human cryftalline; and grants, that from the fpherical form of it in the fifh, fuch a change as he attributes to the lens in quadrupeds cannot take place in that clafs of animals. The lenfes which I have examined in the manner abovementioned were the human, thofe of the ox, the fheep, the rabbit, and the fifh, and in all the fame lamellated ftructure is obfervable; even in the fpherical lens of the fifh thefe lamellæ are equally diftinct, but without the fmalleft appearance of a mufcle.

" From thefe circumftances I cannot avoid the conclufion, that they do not exift; at the fame time I am perfuaded that Mr Young met with appearances which he fuppofed were mufcles; but I am fatisfied he will readily acknowledge, that the examination of the cryftalline lens in its vifcid glutinous ftate, is not only attended with much difficulty, but that the fmalleft change of circumftances might lead to error; which I apprehend may, probably, have been the cafe in that inftance.

" Upon examining it after boiling, or expofing it to a gradual degree of heat before the fire, when it may be handled with freedom, he will readily obferve (without a glafs) the numerous lamellæ, and the arrangement of their fibres, which I have defcribed.

" Another opinion has been fanctioned by many refpectable writers, of the effects of the ciliary proceffes in changing the fhape and fituation of the lens; fome fuppofed

(D) " Et lente ob cataractam extracta vel depofita oculum tamen ad varias diftantias videre, ut in nobili viro video abfque ullo experimento quo eam facultatem recuperaverit. Etfi enim tunc ob diminutas vires quæ radios uniunt, æger lente vitrea opus habet, eadem tamen lens in omni diftantia fufficit."—*Haller, El. Phyf.*

" La lentille criftalline n'eft cependant point de première neceffité pour la vifion. Aujourd'hui, dans l'opération de la catarac̄te on l'enlève entièrement, et la vifion n'en fouffre point."—*De la Metherie Vues Phyfiologiques.* See alfo *De la Hire, Hamberger Phyfiolog.*

fuppofed it to poffefs the power of changing the figure of the cryftalline, rendering it more or lefs convex (E); others, that it removed it nearer to the cornea (F); and others, that it removed it nearer the retina (G).

"The advocates for thefe different opinions all agree in attributing thefe effects to a fuppofed mufcularity of the ciliary proceffes.

"Of the ftructure of thefe proceffes Haller obferves, 'In omni certe animalium genere proceffus ciliares abfque ulla mufculofa funt fabrica, mere vafculofi vafculis ferpentinis percurfi molli facti membrana.' Which ftructure, I believe, at prefent is univerfally admitted. But even fuppofing them mufcular, fuch is their delicacy of ftructure, their attachment, and direction, that we cannot poffibly conceive them adequate to the effects afcribed to them. Befide, what we obferved of the mufcles of the lens itfelf, alfo applies to the proceffes, viz. that they may be deftroyed, as in couching or extraction, and yet the eye be capable of adapting itfelf to the different diftances of objects. For a more full refutation of thefe opinions, fee Haller's large work.

The Situation, Structure, and Action of the external Mufcles (H).

"Upon carefully removing the eyelids, with their mufcles, we are prefented with the mufcles of the eye itfelf, which are fix in number; four called recti, or ftraight; and two oblique; fo named from their direction, (fee Pl. 3. Appen. fig. 4.) AAAA, the tendons of the recti mufcles, where they are inferted into the fclerotic coat, at the anterior part of the eye. B, the fuperior oblique, or trochlearis, as fometimes called, from its paffing through the loop or pulley connected to the lower angle of the orbiter notch in the os frontis; it paffes under the fuperior rectus mufcle, and backwards to the pofterior part of the eye, where it is inferted by a broad flat tendon into the fclerotic coat. C, the inferior oblique, arifing tendinous from the edge of the orbiter procefs of the fuperior maxillary bone, paffes ftrong and flefhy over the inferior rectus, and backwards under the abductor to the pofterior part of the eye, where it is alfo inferted by a broad flat tendon into the fclerotic coat. DDD, the fat in which the eye is lodged. In fig. 5. we have removed the bones forming the external fide of the orbit, with a portion of the fat, by which we have a diftinct view of the abductor. ABC, three of the recti mufcles, arifing from the back part of the orbit, paffing ftrong, broad, and flefhy over the ball of the eye, and inferted by flat, broad tendons into the fclerotic coat, at its anterior part. D, the tendon of the fuperior oblique mufcle. E, the inferior oblique, fig. 6. A, the abductor of the eye. B, the flefhy belly of the fuperior oblique, arifing ftrong, tendinous, and flefhy from the back part of the orbit. C, the optic nerve. D and E, the recti mufcles.

"The ufe afcribed to thefe different mufcles, is that of changing the direction of the eye, to turn it upwards, downwards, laterally, or in any of the intermediate directions, accommodated either to the different fituation of objects, or to exprefs the different paffions of the mind, for which they are peculiarly adapted. But is it inconfiftent with the general laws of nature, or even with the animal œconomy, that from their combination they fhould have a different action, and thus an additional ufe? To illuftrate this we need only witnefs the action of almoft any fet of mufcles in the body; for example, in lifting a weight, the combined action of the mufcles of the arm, fhoulder, and cheft, is different from the individual action of either fet, or of any individual mufcle; or an inftance nearer our purpofe may be adduced, viz. the actions of the mufcles of the cheft and belly, making a compreffion upon the vifcera, as in the difcharge of urine, fæces, &c. But to queftion this fact would be to queftion the influence of the will in any one of the almoft infinite variety of motions in the human body.

"I prefume, therefore, it will be admitted that we have the fame power over thefe mufcles of the eye as of others, and I believe we are no lefs fenfible of their combined action; for example, after viewing an object at the diftance of half a mile, if we direct our attention to an object but ten feet diftance, every perfon muft be fenfible of fome exertion; and if our attention be continued but for a fhort time, a degree of uneafinefs and even pain in the ball of the eye is experienced; if again we view an object within the focal diftance, *i. e.* within fix or feven inches, fuch is the intenfity of the pain that the exertion can be continued but a very fhort time, and we again relieve it by looking at the more diftant objects; this, I believe, muft be the experience of every perfon, whofe eyes are in the natural and healthy ftate, and accordingly has been obferved by almoft every writer upon optics.

"But the power of this combination, even from analogy, appears too obvious to need further illuftration. I fhall therefore next endeavour to point out their precife action.

"Suppofing the eye in its horizontal natural pofition; I fee an object diftinctly at the diftance of fix feet, the picture of the object falls exactly upon the retina; I now direct my attention to an object at the diftance of fix inches, as nearly as poffible in the fame line; although the rays from the firft object ftill fall upon my eye, while viewing the fecond, it does not form a diftinct picture on the retina, although at the fame diftance as before, which fhews that the eye has undergone fome change; for while I was viewing the firft object I did not fee the fecond diftinctly, although in the fame line: and now, *vice verfa*, I fee the fecond diftinctly, and not the firft; the rays from the firft, therefore, as they ftill fall upon the eye, muft either meet before or behind the retina; but we have fhewn that the rays from the more diftant object convene fooner than thofe from the lefs

(E) *Des Cartes*, *Scheinerus*, *Bidious*, *Mollinettus*, *Sanctorius*, *Jurin*.

(F) *Kepler*, *Zinn*, *Porterfield*.

(G) *La Chariere*, *Perrault*, *Hartfocker*, *Briffeau*, and *Derham*.

(H) For the accuracy of the reprefentation I have annexed (in Pl. 3. Appen.) I can vouch, having been at much pains in the diffection; from which I had the painting taken by a moft accurate hand, Mr S. Edwards, a gentleman well known for his abilities in the plates of that admirable work, the Flora Londinenfis.

less distant object, therefore the picture of the object at six feet falls before, while the other forms a distinct image upon the retina; but as my eye is still in the same place as at first, the retina has by some means or other been removed to a greater distance from the fore part of the eye to receive the picture of the nearer object, agreeable to the principle page 455. From which it is evident, that to see the less distant object either the retina should be removed to a greater distance, or the refracting power of the media should be increased: but I hope we have shewn that the lens, which is the greatest refracting medium, has no power of changing itself. Let us next inquire, if the external muscles, the only remaining power the eye possesses, are capable of producing those changes. With respect to the anterior part of the eye, we have seen the situation of those muscles; the recti strong, broad, and flat, arising from the back part of the orbit, passing over the ball as over a pulley, and inserted by broad flat tendons at the anterior part of the eye; the oblique inserted toward the posterior part, also by broad flat tendons; when they act jointly, the eye being in its horizontal position, it is obvious, as every muscle in action contracts itself, the four recti by their combination must necessarily make a comparison upon the different parts of the eye, and thus elongate its axis, while the oblique muscles serve to keep the eye in its proper direction and situation. For my own part, I have no more difficulty in conceiving of this combination of those muscles than I have at present of the different flexors of my fingers in holding my pen. But other corresponding effects are also produced by this action; not only the distance between the anterior and posterior parts of the eye is increased, but of consequence the convexity of the cornea, from its great elasticity, is also increased, and that in proportion to the degree of pressure, by which the rays of light passing through it are thence necessarily more converged. But another effect, and one not inconsiderable, is, that by this elongation of the eye, the media, viz. the aqueous, crystalline, and vitreous humours through which the rays pass, are also lengthened, of consequence their powers of refraction are proportionably increased; all which correspond with the general principle. It may however be said, that as the four recti muscles are larger and stronger than the two oblique, the action of the former would overcome that of the latter, and thus draw back the whole globe of the eye; but does not the fat at the posterior part of the orbit also afford a resistance to the too great action of the recti muscles, especially as it is of a firm consistence, and the eye rests immediately upon it? Admitting then that this is the operation of the external muscles when in a state of contraction, it is also to be observed, we have the same power of relaxing them, in proportion to the greater distance of the object, until we arrive at the utmost extent of indolent vision.

"But, as a further testimony of what has been advanced, I had recourse to the following experiment, which will shew that the eye is easily compressible, and that the effects produced correspond with the principles I have endeavoured to illustrate.

"With the common *speculum oculi* I made a very moderate degree of pressure upon my eye, while directing my attention to an object at the distance of about twenty yards; I saw it distinctly, as also the different intermediate objects; but endeavouring to look beyond it, every thing appeared confused. I then increased the pressure considerably, in consequence of which I was enabled to see objects distinctly at a much nearer than the natural focal distance; for example, I held before my eye, at the distance of about two inches, a printed book; in the natural state of the eye I could neither distinguish the lines nor letters; but upon making pressure with the speculum I was enabled to distinguish both lines and letters of the book with ease.

"Such then I conceive to be the action and effects of the external muscles, and which I apprehend will also apply in explaining many other phænomena of vision; some of those it will not be improper at present briefly to notice.

"First, may not the action of those muscles have more or less effect in producing the changes of vision which take place in the different periods of life? At the same time the original conformation of the eye, the diminution of its humours, and, probably, of the quantity of fat upon which the eye is lodged, are also to be taken into the account. But the external muscles becoming irregular and debilitated by old age, in common with every other muscle of the body, are not only incapable of compensating for these losses, but cannot even perform their wonted action, and thus necessarily have considerable influence in impairing vision. Again, does not the habit of long sight so remarkable in sailors and sportsmen, who are much accustomed to view objects at a great distance, and that of short sight, as of watchmakers, seal-cutters, &c. admit of an easy solution upon this principle? as we know of no part of the body so susceptible of an habitual action as the muscular fibre.

"Secondly. How are we to account for the weaker action of one eye in the case of squinting? That this is the fact has been well ascertained; Dr Reid (1) upon this subject observes, that he has examined above twenty persons that squinted, and found in all of them a defect in the sight of one eye. Porterfield and Jurin have made the same observation.

"The distorted position of the eye has, I believe, been generally attributed to the external muscles; but no satisfactory reason has ever been given why the eye, directed towards an object, does not see it distinctly at the same distance as with the other. The state of the iris here cannot explain it, as it contracts and dilates in common with the other; nor can we suppose any muscles the lens might possess could have any effect, as they are not at all connected with the nature of this disease.

"But the action of the external muscles, I apprehend, will afford us a satisfactory explanation. When the eye is turned from its natural direction, for example, towards the inner canthus, it is obvious that the *adductor* muscle is shortened, and its antagonist, the *abductor*, lengthened; consequently, as the abductor has not the same power of contracting itself with the adductor, when the eye is directed towards an object, their power of action being different and irregular, the compression

(1) See his Inquiry into the Human Mind, page 322.

compreſſion made upon the eye and its humours muſt alſo be equally irregular, and therefore inſufficient to produce the regular changes in the refraction and ſhape of the eye we have ſhewn to be neceſſary in adapting it to the different diſtances of objects. The effects produced by making a partial preſſure upon the eye with the finger, or *ſpeculum oculi*, before noticed, would alſo appear to favour this explanation.

"Thirdly. May it not in part be owing to the loſs of this combined action of the external muſcles, and the difficulty of recovering it, that the operation of couching is ſometimes unſucceſsful, eſpecially when the cataract has been of long ſtanding? This cannot be attributed to the iris, for it perhaps, dilates and contracts as before: nor to the muſcles of the lens, for they are removed; nor to the ſtate of the nerve, for it is ſtill ſenſible to light; and yet the patient cannot ſee objects diſtinctly; and it is not an uncommon circumſtance, even when the operation ſucceeds, that the ſight is ſlowly and gradually recovered. Inſtances have occurred, Mr Bell (K) obſerves, of the ſight becoming gradually better for ſeveral months after the operation.

"When we have been long out of the habit of combining our muſcles in almoſt any one action of life, as walking, dancing, or playing upon a muſical inſtrument, we in a great meaſure loſe the combination, and find a difficulty in recovering it, in proportion to the length of time we had been deprived of it; but the individual action of each muſcle remains as before. Thus, probably, with the muſcles of the eye. A variety of facts of a ſimilar nature muſt preſent themſelves to every perſon converſant in the ſcience of optics, which may admit of a ſimilar explanation.

"I have thus endeavoured, firſt, to point out the limited action of the iris, and of conſequence the inſufficiency of this action for explaining viſion. Secondly, to prove that the lens poſſeſſes no power of changing its form to the different diſtances of objects. Thirdly, that to ſee objects at different diſtances, correſponding changes of diſtance ſhould be produced between the retina and the anterior part of the eye, as alſo in the refracting powers of the media through which the rays of light are to paſs. And, fourthly, that the combined action of the external muſcles is not only capable of producing theſe effects, but that from their ſituation and ſtructure they are alſo peculiarly adapted to produce them.

"It is not then conſiſtent with every principle in the œconomy of nature and of philoſophy, ſeeing the imperfections of the principles which have hitherto been employed in explaining the phænomena in queſtion, to adopt the one before us, until (agreeable to one of the eſtabliſhed rules in philoſophizing) other phænomena occur, by which it may be rendered either more general, or liable to objections?

"I have now finiſhed what was propoſed. I have declined entering into an extenſive view of the ſtructure of the eye, or any of the general principles of optics, as thoſe ſubjects have been more ably treated in the works already cited, and thus would certainly have deſtroyed every claim to attention, which theſe few pages in their preſent form may poſſibly poſſeſs; and if I ſhould be ſo fortunate as to ſucceed in eſtabliſhing the principle I have propoſed, for explaining the phænomena dependent upon this more important organ of our body (if any part poſſeſſes a pre-eminence in nature), I alſo hope it may, in abler hands, admit of ſome practical application, in alleviating the diſeaſes to which its delicate organization ſo particularly expoſes it (L)."

VITALITY, the power of ſubſiſting in life, which the faſhionable philoſophers of the French and German ſchools attribute to *chemiſtry*. For a confutation of their abſurd and impious jargon on this ſubject, we refer our readers, with ſome degree of confidence, to the articles PHYSIOLOGY (*Encycl.*), and *Animal* SUBSTANCES (*Suppl.*)

VITTORIA, *St Juan de*, a city of Peru.—*Morse.*

VIVERRA (ſee *Encycl.*) A new ſpecies of this genus of animals was diſcovered by Vaillant during his laſt travels in Africa; at leaſt he ranks under the generic name *Viverra*, the animal of which he gives the following deſcription. Its body was of the ſize of that of a kitten ſix months old: it had a very large noſe, the upper jaw exceeding the lower near two-thirds of an inch in length, and forming a ſort of moveable ſnout reſembling that of the *coati* of Guiana. The fore feet were armed with four large claws, very ſharp and curved; the hind ones have each five, but they are ſhort and blunt. All the fur on the upper part of the body is marked with croſs bands of a deep brown colour, on a ground of light brown with which many white hairs are intermixed. The lower part of the body and inſides of the legs are of a reddiſh white. The tail, which is very fleſhy, and more than two-thirds longer than the body, is black at the tip, and the reſt brown, intermixed with white hairs.

This animal employs its fore paws to dig very deep holes in the earth, in which it remains concealed during the day, not going out till ſun-ſet in queſt of food.

The Hottentots who accompanied our traveller called it *muys-hond* (a mouſe dog); a general name among the inhabitants of the Cape for all the ſmaller carnivorous quadrupeds.

VIVES (Ludovicus), the contemporary and friend of Eraſmus, was a native of Valentia in Spain. Though well trained in all the ſubtleties of the ſcholaſtic philoſophy at Paris, he had the good ſenſe to diſcover its futility, and diligently applied himſelf to more uſeful ſtudies. At Louvain he undertook the office of a preceptor, and exerted himſelf with great ability and ſucceſs in correcting barbariſm, chaſtiſing the corrupters of learning,

(K) See his Syſtem of Surgery.

(L) Since the above pages have been written, I have found, upon conſulting ſome of the earlieſt writers, that the effects of the external muſcles did not altogether eſcape their attention; at the ſame time they had no diſtinct idea of their action: I muſt therefore diſclaim the originality of the thought, although I had never met with it before the circumſtances already noticed, of the inſufficiency of the iris, had ſuggeſted it. If, however, I have ſucceeded in pointing out the preciſe action of thoſe muſcles, and its application to the general principles of viſion, in which, I believe, I have never been anticipated, it will be the height of my wiſhes.

learning, and reviving a tafte for true fcience and elegant letters. Erafmus, with whom he lived upon the footing of intimate friendfhip, fpeaking of Vives when he was only 26 years of age, fays, that there was no part of philofophy in which he did not excel; and that he had made fuch proficiency in learning, and in the arts of fpeaking and writing, that he fcarcely knew his equal. He wrote a commentary upon Auguftine's treatife *De Civitate Dei*, which difcovers an extenfive acquaintance with ancient philofophy. Henry VIII. of England, to whom he dedicated this work, was fo pleafed with it, that he invited the author to his court, and made him preceptor to his daughter Mary. Though he difcharged his office with great fidelity, yet in confequence of his oppofition to the king's divorce, he fell under his difpleafure; and it was not without difficulty that he efcaped to Bruges, where he devoted the remainder of his days to ftudy. He died in the year 1537, or, according to Thuanus, in 1541. With Erafmus and Buddæus he formed a triumvirate of literature which did honour to the age. He wrote *De Prima Philofophia*, "On the Firft Philofophy;" *De Explanatione Effentiarum*, "On the Explanation of Effences;" *De Cenfura Veri*, "On the Teft of Truth;" *De Initiis, Sectis, et Laudibus Philofophiæ*, "On the Origin, Sects, and Praifes of Philofophy;" and *De Corruptis Artibus et Tradendis Difciplinis*; "On the Corruption of Science, and on Education." Thefe writings, of which the two laft are the moft valuable, difcover great ftrength of judgment, an extenfive knowledge of philofophy, much enlargement of conception, uncommon fagacity in detecting the errors of ancient and modern philofophers, particularly of Ariftotle and his followers, and, in fine, a mind capable of attempting things beyond the ftandard of the age in which he lived. To all this he added great perfpicuity and elegance of ftyle, not unworthy of the friend of Erafmus.

ULIETEA, one of the Society Iflands in the S. Pacific Ocean, is about 7 or 8 leagues from the ifland of Huaheine, at S. W. by W. There are 9 uninhabited iflands weft of it. The fouth end lies in lat. 16 55 S. and long. 151 20 W.—*Morse*.

ULSTER, a mountainous and hilly county of New-York, containing all that part of the State bounded eafterly by the middle of Hudfon's river, foutherly by the county of Orange, wefterly by the ftate of Pennfylvania, and the weft branch of Delaware river, and northerly by the county of Albany. In 1790, it contained 29,397 inhabitants, including 2,906 flaves. In 1796, there were 4,429 of the inhabitants qualified to be electors. It is divided into 16 townfhips. Chief town, Kingfton. A part of this county and that of Otfego, were erected into a feparate county, January, 1797.—*ib.*

ULTRAMARINE is a very fine blue powder, almoft of the colour of the corn flower or blue-bottle, which has this uncommon property, that, when expofed to the air or a moderate heat, it neither fades nor becomes tarnifhed. On this account it is ufed in painting; but it was employed formerly for that purpofe much more than at prefent, as fmalt, a far cheaper article, was not then known. (See Cobalt, in this *Suppl.*) Ultramarine is made of the blue parts of the lapis lazuli, by feparating them as much as poffible from the other coloured particles with which they are mixed, and reducing them to a fine powder. The real lapis lazuli is found in the mountains of that part of Tartary called Bucharia, which extends eaftward from the Cafpian fea, and particularly at Kalab and Budukfchu. It is fent thence to the Eaft Indies, and from the Eaft Indies to Europe. Good ultramarine muft be of a beautiful dark colour, and free from fand as well as every other mixture. It muft unite readily with oil; it muft not become tarnifhed on a red-hot tile or plate of iron, and it ought to diffolve in ftrong acids, almoft like the zeolite, without caufing an effervefcence. In the year 1763, an ounce of it at Paris coft four pounds fterling, and an ounce of *cendre d'outremer* which is the refufe, two pounds. The bafis of this colour was long fufpected to be copper, but the experiments of Margraff fhewed that it was iron, in fome unknown ftate of combination. New light has been thrown on this fubject by Morveau, who has difcovered that felenite loaded with iron, when decompofed by carbonaceous matter, yields a blue fulphuret of iron of equal permanency with the true ultramarine.

At prefent, fmalt of a good colour is often purchafed at a dear rate and fubftituted for ultramarine; and it is found that the colour of this preparation of cobalt is more durable in the fire than even that of the lapis lazuli. For the analyfis of lapis lazuli, fee Mineralogy, n° 69. *Suppl.*

ULYSSES, one of the military townfhips in Onondago county, New-York, fituated at the fouthern end of Cayuga Lake, having Hector on the weft, and Dryden on the eaft, which laft townfhip is included within the jurifdiction of Ulyffes, which was incorporated in 1794. In 1796, 38 of the inhabitants were electors.—*Morse*.

UMBAGOG, a large lake of New-Hampfhire, next in fize to Lake Winipifeogee. It lies in Grafton county, and a fmall part of it in the Diftrict of Maine.—*ib.*

UNADILLA, a river of the ftate of New-York, called alfo *Tianaderha*, runs fouthward, and joining the Main Branch, forms Chenengo river.—*ib.*

Unadilla, a townfhip of New-York, Otfego county, on the northern fide of the main branch of Chenengo river. It is about 110 miles fouth-weft of Albany; and, in 1796, 502 of its inhabitants were electors. In the fame year, the townfhips of Suffrage, Otfego, and Butternuts, were taken from this townfhip, and incorporated.—*ib.*

UNAMI, a tribe of the Delaware Indians, confidered to be the head of that nation.—*ib.*

UNDERHILL, a townfhip of Vermont, Chittenden county, 12 miles eaft of Colchefter, and contains 65 inhabitants.—*ib.*

UNION, a county of South-Carolina, Pinckney diftrict, containing 7,693 inhabitants, of whom 6,430 are whites, and 1,215 flaves. It fends two reprefentatives and one fenator to the ftate legiflature. Chief town, Pinckneyville.—*ib.*

Union, a rocky townfhip in Tolland county, Connecticut, weft of Woodftock, and about 12 miles N. E. of Tolland.—*ib.*

Union, a townfhip of the Diftrict of Maine, Lincoln county, containing 200 inhabitants. It was incorporated in 1786, and lies 290 miles from Bofton.—*ib.*

Union, a poft-town of the ftate of New-York, Tioga county, on the N. fide of Sufquehannah river, and weft of the mouth of the Chenengo, 122 miles S. E. by E. of of Williamfburg, on Geneffee river, 24 E. N. E. of Athens, or Tioga Point, 92 S. W. of Cooperftown, and 340 N. by W. of Philadelphia. In 1796, there were in the townfhip, 284 of the inhabitants qualified electors. —*ib.*

Union *River*, or *Plantation No.* 6, in the Diftrict of Maine, is fituated in Hancock county, 25 miles N. E. of Penobfcot.—*ib.*

Union *River*, in the county of Hancock, Diftrict of Maine, empties into Blue Hill Bay, on the E. fide of Penobfcot Bay. Long-Ifland, in this bay, is in lat. 44 25, and long 67 45.—*ib.*

UNION-TOWN, a poft-town of Pennfylvania, Fayette county, on Redftone Creek. It contains a church, a ftone gaol, and a brick court-houfe, and about 80 dwelling-houfes. Near it are two valuable merchant mills. It is the feat of the county courts, and is 14 miles S. by E. of Brownfville, where Redftone Creek enters the Monongahela, 58 miles S. of Pittfburg, 24 N. E. of Morgantown, in Virginia, and 327 W. of Philadelphia.—*ib.*

UNITAS, a village of N. Carolina, fituated at the head of Gargal's Creek.—*ib.*

UNITED STATES of America, fituated between 31° and 46° north latitude, 8° E. and 24° W. lon. from Philadelphia, 64° and 96° W. lon. from London, is in length 1250 miles, and in breadth 1040. It is bounded north and eaft, by Britifh America, or the Provinces of Upper and Lower Canada, and New Brunfwick; fouth-eaft, by the Atlantic Ocean; fouth by Eaft and Weft Florida; weft, by the river Miffiffippi.

The American Republic, confifts of three grand divifions, denominated the *Northern*, or more properly *Eaftern*, *Middle* and *Southern* States. The *firft* divifion, (the Northern or Eaftern States) comprehends Vermont, New Hampfhire, Diftrict of Maine, (belonging to Maffachufetts) Maffachufetts, Rhode Ifland, and Connecticut. Thefe are called the New England States, and comprehend that part of America, which, fince the year 1614, has been known by the name of New England. The *fecond* divifion (the Middle States) comprehends New York, New Jerfey, Pennfylvania, Delaware, and Territory N. W. of Ohio. The *third* divifion (the Southern States) comprehends Maryland, Virginia, Kentucky, North Carolina, Tenneffee, South Carolina, Georgia, and Miffiffippi Territory.

In the treaty of peace, concluded in 1783, the limits of the American United States are more particularly defined in the words following: "And that all difputes which might arife in future on the fubject of the boundaries of the faid United States may be prevented, it is hereby agreed and declared, that the following are and fhall be their boundaries, viz. From the north-weft angle of Nova Scotia, viz. that angle which is formed by a line drawn due north from the fource of St Croix River to the Highlands, along the faid Highlands, which divide thofe rivers that empty themfelves into the river St Lawrence from thofe which fall into the Atlantic Ocean, to the north-wefternmoft head of Connecticut river; thence down along the middle of that river to the forty-fifth degree of north latitude; from thence by a line due weft on faid latitude, until it ftrikes the river Iroquois or Cataraquie; thence along the middle of the faid river into Lake Ontario; through the middle of faid lake, until it ftrikes the communication by water between that lake and Lake Erie; thence along the middle of faid communication into Lake Erie, through the middle of faid lake, until it arrives at the water communication between that lake and Lake Huron; thence through the middle of faid lake to the water communication between that lake and Lake Superior; thence through Lake Superior, northward of the Ifles Royal and Phillipeaux, to the Long Lake; thence through the middle of faid Long Lake, and the water communication between it and the Lake of the Woods, to the faid Lake of the Woods; thence through the faid lake to the moft northweftern point thereof, and from thence, on a due weft courfe, to the River Miffiffippi; thence by a line to be drawn along the middle of faid River Miffiffippi, until it fhall interfect the northernmoft part of the thirty-firft degree of north latitude.

"South, by a line to be drawn due eaft from the determination of the line laft mentioned, in the latitude of thirty-one degrees north of the equator, to the middle of the River Apalachicola, or Catahouche; thence along the middle thereof to its junction with the Flint River; thence ftraight to the head of St Mary's River; and thence down along the middle of St Mary's River to the Atlantic Ocean.

"Eaft, by a line to be drawn along the middle of the River St Croix, from its mouth, in the Bay of Fundy, to its fource, and from its fource directly north, to the aforefaid Highlands, which divide the rivers that fall into the Atlantic Ocean from thofe which fall into the River St Lawrence; comprehending all iflands within twenty leagues of any part of the fhores of the United States, and lying between lines to be drawn due eaft from the points where the aforefaid boundaries between Nova Scotia on the one part, and Eaft Florida on the other, fhall refpectively touch the Bay of Fundy and the Atlantic Ocean, excepting fuch iflands as now are, or heretofore have been, within the limits of the faid province of Nova Scotia."

The territory of the United States, according to Mr Hutchins, contains, by computation, a million of fquare miles, in which are

miles, in which are	640,000,000 acres.
Deduct for water	51,000,000
Acres of land in the United States	589,000,000

That part of the United States, comprehended between the weft boundary line of Pennfylvania, on the eaft; the boundary line between Great Britain and the United States, extending from the northweft corner of Pennfylvania, to the northweft extremity of the Lake of the Woods, on the north; the river Miffiffippi, to the mouth of the Ohio, on the weft; and the river Ohio on the fouth, to the aforementioned bounds of Pennfylvania, contains, by computation, about 411,000 fquare miles, in which are

fquare miles, in which are	263,040,000 acres
Deduct for water	43,040,000
To be difpofed of by order of Congrefs, when purchafed of the Indians	220,000,000

The whole of this immenfe extent of unappropriated weftern territory, containing as above ftated, 220,000,000 of acres, and feveral large tracts fouth of the

the Ohio, (A) have been, by the ceſſion of ſome of the original thirteen ſtates, and by the treaty of peace, transferred to the federal government, and are pledged as a fund for ſinking the debt of the United States. Of this territory the Indians now poſſeſs a very large proportion. Mr Jefferſon, in his report to Congreſs, November 8, 1791, deſcribes the boundary line between us and the Indians, as follows: "Beginning at the mouth of the Cayahoga (which falls into the ſouthernmoſt part of the Lake Erie) and running up the river to the portage, between that and the Tuſcarora (or N. E.) branch of the Muſkingum; then down the ſaid branch to the forks, at the croſſing place above Fort Lawrence; then weſtwardly, towards the portage of the Great Miami, to the main branch of that river; then down the Miami, to the fork of that river, next below the old fort which was taken by the French, in 1752; thence due weſt to the river De la Panſe (a branch of the Wabaſh) and down that river to the Wabaſh. So far the line is preciſely determined, and cleared of the claims of the Indians. The tract comprehending the whole country within the above deſcribed line, the Wabaſh, the Ohio, and the weſtern limits of Pennſylvania, contains about 55,000 ſquare miles. How far on the weſtern ſide of the Wabaſh, the ſouthern boundary of the Indians has been defined, we know not. It is only underſtood in general, that their title to the lower country, between that river and the Illinois, was formerly extinguiſhed by the French, while in their poſſeſſion."

Eſtimate of the number of acres of water, north and weſtward of the river Ohio, within the territory of the United States.

	Acres.

	7,990,000	
Total,	51,000,000	

It may in truth be ſaid, that no part of the world is ſo well watered with ſprings, rivulets, rivers, and lakes, as the territory of the United States. By means of theſe various ſtreams and collections of water, the whole country is checkered into iſlands and peninſulas. The United States, and indeed all parts of North America, ſeem to have been formed by nature for the moſt intimate union. The facilities of navigation render the communication between the ports of Georgia and New-Hampſhire far more expeditious and practicable, than between thoſe of Provence and Picardy in France; Cornwall and Caithneſs, in Great-Britain; or Gallicia and Catalonia, in Spain. The canals opening between Suſquehannah and Delaware, between Paſquetank and Elizabeth Rivers, in Virginia, and between the Schuylkill and Suſquehannah, will open a communication from the Carolinas to the weſtern counties of Pennſylvania and New-York. The improvement of the Patowmak, will give a paſſage from the ſouthern States to the weſtern parts of Virginia, Maryland, Pennſylvania, and even to the lakes. From Detroit, to Alexandria, on the Potowmak, ſix hundred and ſeven miles, are but two carrying places, which together do not exceed the diſtance of forty miles. The canals of Delaware and Cheſapeak will open the communication from South Carolina to New Jerſey, Delaware, the moſt populous parts of Pennſylvania, and the midland counties of New York. Were theſe, and the canal between Aſhley and Cooper Rivers, in South Carolina—the canals in the northern parts of the ſtate of New-York, and thoſe of Maſſachuſetts and New-Hampſhire, all opened, and many of them are in great forwardneſs, North America would thereby be converted into a cluſter of large and fertile iſlands, communicating with each other with eaſe and little expenſe, and in many inſtances without the uncertainty or danger of the ſeas.

There is nothing in other parts of the globe which reſembles the prodigious chain of lakes in this part of the world. They may properly be termed inland ſeas of freſh water; and even thoſe of the ſecond or third claſs in magnitude, are of larger circuit than the greateſt lake in the eaſtern continent, the Caſpian Sea excepted. Some of the moſt northern lakes belonging to the United States, have never been ſurveyed, or even viſited till lately by white people; of courſe we have no deſcription of them which can be relied on as accurate. Others have been partially ſurveyed, and their relative ſituation determined. The beſt account of them which we have been able to procure is as follows:

The Lake of the Woods, the moſt northern in the United States, is ſo called from the large quantities of wood growing on its banks; ſuch as oaks, pines, firs, ſpruce, &c. This lake lies nearly eaſt of the ſouth end of Lake Winnepeck, and is ſuppoſed to be the ſource or conductor of one branch of the river Bourbon, if there be ſuch a river. Its length from eaſt to weſt is ſaid to be about ſeventy miles, and in ſome places it is forty miles wide. The Killiſtino Indians encamp on its borders to fiſh and hunt. This lake is the communication between the Lakes Winnepeek and Bourbon, and Lake Superior.

Rainy

(A) Ceded by North Carolina, South Carolina, and Georgia, with certain reſervations for the Indians and other purpoſes.

United States.

Rainy, or Long Lake, lies east of the Lake of the Woods, and is said to be nearly an hundred miles long, and in no part more than twenty miles wide.

Eastward of this lake, lie several small ones, which extend in a string to the great carrying place, and thence into Lake Superior. Between these little lakes are several carrying places, which render the trade to the north-west difficult, and exceedingly tedious, as it takes two years to make one voyage from Michilimakkinac to these parts.

Lake Superior, formerly termed the Upper Lake, from its northern situation, is so called from its magnitude, it being the largest on the continent. It may justly be termed the Caspian of America, and is supposed to be the largest body of fresh water on the globe. According to the French charts, it is 1500 miles in circumference (B). A great part of the coast is bounded by rocks and uneven ground. The water is pure and transparent, and appears generally, throughout the lake, to lie upon a bed of huge rocks. It has been remarked, in regard to the waters of this lake, (with how much truth we cannot say) that although their surface, during the heat of summer, is impregnated with no small degree of warmth, yet, on letting down a cup to the depth of about a fathom, the water drawn from thence is cool and refreshing.

The situation of this lake, from the most accurate observations which have come to our knowledge, lies between lat. 46° and 48° 30′ N. and lon. 84° and 91° 30′ W. from London.

There are many islands in this lake, two of them have each land enough, if proper for cultivation, to form a considerable province; especially Isle Royal, near the N. W. coast of the lake, which is not less than an hundred miles long, and in many places forty broad. The natives suppose these islands are the residence of the Great Spirit.

Two large rivers empty themselves into this lake, on the north and north-east side; one is called the Nipegon, which leads to a tribe of the Chipeways, who inhabit a lake of the same name, and the other is the Michipicooton river, the source of which is towards James's Bay, from whence there is said to be but a short portage to another river which empties itself into that bay.

Not far from the Nipegon is a small river, that just before it enters the lake, has a perpendicular fall from the top of a mountain of six hundred feet. [*Carver.*] It is very narrow, and appears at a distance like a white garter suspended in the air. There are upwards of thirty other rivers, which empty into this lake, some of which are of a considerable size. On the south side of it is a remarkable point or cape of about sixty miles in length, called point Chegomegan. About an hundred miles west of this cape, a considerable river falls into the lake, the head of which is composed of a great assemblage of small streams. This river is remarkable for the abundance of virgin copper that is found on and near its banks. Many small islands, particularly on the eastern shores, abound with copper ore lying in beds, with the appearance of copperas. This metal might be easily made a very advantageous article of commerce. This lake abounds with fish, particularly trout and sturgeon; the former weigh from twelve to fifty pounds, and are caught almost any season of the year in great plenty. Storms affect this lake as much as they do the Atlantic Ocean; the waves run as high, and the navigation is equally dangerous. It discharges its waters from the south-east corner, through the Straits of St Marie, which are about forty miles long. Near the upper end of these straits is a rapid, which, though it is impossible for canoes to ascend, yet, when conducted by careful pilots, may be descended without danger.

Though Lake Superior is supplied by near forty rivers, many of which are large, yet it does not appear that one tenth part of the waters which are conveyed into it by these rivers is discharged by the abovementioned straits. Such a superabundance of water can be disposed of only by evaporation (C). The entrance into this lake from the straits of St Marie, affords one of the most pleasing prospects in the world. On the left may be seen many beautiful little islands that extend a considerable way before you; and on the right, an agreeable succession of small points of land, that project a little way into the water, and contribute, with the islands, to render this delightful bason calm, and secure from those tempestuous winds, by which the adjoining lake is frequently troubled.

Lake Huron, into which you enter through the Straits of St Marie, is next in Magnitude to Lake Superior. It

(B) Carver supposes it exceeds 1600 miles.

(C) That such a superabundance of water should be disposed of by evaporation is no singular circumstance. "There are some seas," says an ingenious correspondent who has not obliged me with his name, "in which there is a pretty just balance between the waters received from rivers, brooks, &c. and the waste by evaporation. Of this the Caspian Sea in Asia affords an instance; which though it receives several large rivers, has no outlet. There are others, (to speak in borrowed language) whose expense exceeds their income; and these would soon become bankrupt, were it not for the supplies which they constantly receive from larger collections of water, with which they are connected; such are the Black and Mediterranean seas; into the former of which there is a constant current from the Mediterranean through the Bosphorus of Thrace; and into the latter, from the Atlantic, through the Straits of Gibraltar. Others again derive more from their tributary streams than they lose by evaporation. These give rise to large rivers. Of this kind are the Dambea, in Africa, the Winnipiseogee, in New Hampshire, Lake Superior and other waters in North America; and the quantity they discharge is only the difference between the influx and the evaporation. It is observable that on the shores the evaporation is much greater than at a distance from them on the ocean. The remarkable cluster of lakes in the middle of North America, of which Lake Superior is one, was doubtless designed by a wise Providence, to furnish the interior parts of the country with that supply of vapours, without which, like the interior parts of Africa, they must have been a mere desert. It may be thought equally surprising that there should be any water at all discharged from them, as that the quantity should bear so small a proportion to what they receive." [*Anonymous* MS.]

United States.

It lies between lat. 43° 30′ and 46° 30′ N. and between long. 80° and 84° 30′ W. from London. Its circumference is about one thousand miles. On the north side of this lake is an island called Manatou, signifying a place of spirits, and is considered as sacred by the Indians. On the south-west part of this lake is Saganaum Bay, about eighty miles in length, and about eighteen or twenty miles broad. On its banks are great quantities of sand cherries. Thunder Bay, so called from the thunder that is frequently heard here, lies about half way between Saganaum Bay and the north-west corner of the lake. It is about nine miles across either way. The fish are the same as in Lake Superior. At the north-west corner this lake communicates with Lake Michigan, by the Straits of Michillimakkinac.

The Chippeway Indians live scattered around this lake; particularly near Saganaum Bay. Their country, however, is to the eastward of this lake.

Michigan Lake lies between latitude 42° 10′ and 46° 30′ north; and between 11° and 13° west long. from Philadelphia. Its computed length is 280 miles, from north to south; its breadth from 60 to 70 miles. It is navigable for shipping of any burthen; and at the northeastern part communicates with Lake Huron, by a strait six miles broad, on the south side of which stands fort Michillimakkinac, which is the name of the strait. In this lake are several kinds of fish, particularly trout of an excellent quality, weighing from 20 to 60 pounds, and some have been taken in the Straits of Michillimakkinac of 90 pounds. Westward of this lake are large meadows, said to extend to the Mississippi. It receives a number of rivers from the west and east, among which is the river St Joseph, very rapid and full of islands. It springs from a number of small lakes, a little to the north-west of the Miami village, and runs north-west into the south-east part of the lake. On the north side of this river is fort St Joseph, from which there is a road bearing north of east, to Detroit. The Powtewatimie Indians, who have about 200 fighting men, inhabit this river opposite fort St Joseph.

Between Lake Michigan on the west, and Lakes Huron, St Clair, and the west end of Erie on the east, is a fine tract of country, peninsulated, more than 250 miles in length, and from 150 to 200 in breadth. The banks of the lakes, for a few miles inland, are sandy and barren, producing a few pines, shrub oaks and cedars. Back of this from either lake, the timber is heavy and good, and the soil luxuriant.

Lake St Clair lies about half way between Lake Huron and Lake Erie, and is about 90 miles in circumference. It receives the waters of the three great Lakes, Superior, Michigan and Huron, and discharges them through the river or strait called Detroit, (or the Strait) into Lake Erie. This lake is of an oval form, and navigable for large vessels. The fort of Detroit is situated on the western bank of the river of the same name, about nine miles below Lake St Clair. The settlements are extended on both sides of the strait or river for many miles towards Lake Erie, and some few above the fort.

Lake Erie is situated between forty-one and forty-three degrees of north latitude, and between 3° 40′ and 8° west longitude. It is nearly three hundred miles long, from east to west, and about forty in its broadest part. A point of land projects from the north side into this lake, several miles, towards the south-east called Long Point. The islands and banks towards the west end of the lake are so infested with rattle-snakes, as to render it dangerous to land on them. The lake is covered near the banks of the islands with large pond lily, the leaves of which lie on the surface of the water so thick, as to cover it entirely for many acres together; on these in the summer season lie myriads of water-snakes basking in the sun. Of the venomous serpents which infest this lake, the hissing snake is the most remarkable. It is about eighteen inches long, small and speckled. When you approach it, it flattens itself in a moment, and its spots, which are of various colours, become visibly brighter through rage; at the same time it blows from its mouth, with great force, a subtile wind, said to be of a nauseous smell; and if drawn in with the breath of the unwary traveller, will infallibly bring on a decline, that in a few months must prove mortal. No remedy has yet been found to counteract its baneful influence. This lake is of a more dangerous navigation than any of the others, on account of the craggy rocks which project into the water, in a perpendicular direction, many miles together from the northern shore, affording no shelter from storms.

Presque Isle is on the south-east shore of this lake, about lat. 42° 10′. From this to Fort Le Beuf, on French Creek, is a portage of $15\frac{1}{2}$ miles. About 20 miles north-east of this is another portage of $9\frac{1}{4}$ miles, between Chataughque Creek, emptying into Lake Erie, and Chataughque Lake, a water of Allegany river.

Fort Erie stands on the northern shore of Lake Erie, and the west bank of Niagara river, in Upper Canada. This lake, at its north-east end, communicates with Lake Ontario, by the river Niagara, which runs from south to north, about 30 miles, including its windings, embracing in its course, Grand Island, and receiving Tonewanto Creek, from the east. About the middle of this river, are the celebrated Falls of Niagara, which are reckoned one of the greatest natural curiosities in the world. The waters which supply the river Niagara rise near two thousand miles to the north-west, and passing through the lakes Superior, Michigan, Huron, and Erie, receiving in their course constant accumulations, at length, with astonishing grandeur, rush down a stupendous precipice of 137 feet perpendicular; and in a strong rapid, that extends to the distance of eight or nine miles below, fall nearly as much more; the river then loses itself in Lake Ontario. The water falls 57 feet in the distance of one mile, before it falls perpendicularly (D). A spectator standing on the bank of the river opposite these falls, would not imagine them to be more than 40 or 50 feet perpendicular height. The noise of these falls, in a clear day and fair wind, may be heard between forty and fifty miles. When the water strikes the bottom,

(D) It is believed by the inhabitants in the neighbourhood of these falls, that formerly they were six miles lower down than they now are, and that the change has been produced by the constant operation of the water. But on a careful examination of the banks of the river, there appears to be no good foundation for this opinion. [*Gen. Lincoln.*]

United States.

tom, its ſpray riſes to a great height in the air, occaſioning a thick cloud of vapours, in which, when the ſun ſhines, may be ſeen, morning and evening, a beautiful rainbow. Fort Niagara, built by the French about the year 1725, is ſituated on the eaſt ſide of Niagara river, at its entrance into Lake Ontario, about 43° 20′ N. lat.

Lake Ontario is ſituated between forty-three and forty-five degrees north lat. and between one and five degrees W. long. Its form is nearly oval. Its greateſt length is from ſouth-weſt to north-eaſt, and its circumference about ſix hundred miles. It abounds with fiſh of an excellent flavour, among which are the Oſwego baſs, weighing three or four pounds. Its banks in many places are ſteep, and the ſouthern ſhore is covered principally with beech trees, and the lands appear good. It receives the waters of the Cheneſſee river from the ſouth, and of Onondago, at Fort Oſwego, from the ſouth-eaſt, by which it communicates, through Lake Oneida, and Wood Creek, with Mohawk river. On the north-eaſt, this lake diſcharges itſelf through the river Cataraqui, (which at Montreal, takes the name of St Lawrence) into the Atlantic Ocean. "It is aſſerted that theſe lakes fill once in ſeven years, and that 1794 was the year when they would be full; but as we are unacquainted with any laws of nature, by which this periodical effect ſhould be produced, we may with propriety doubt the fact." [*Gen. Lincoln.*]

About 8 miles from the weſt end of Lake Ontario, is a curious cavern, which the Meſſiſaugas Indians call *Manito' ah wigwam*, or *houſe of the Devil*. The mountains which border on the lake, at this place, break off abruptly, and form a precipice of 200 feet perpendicular deſcent; at the bottom of which the cavern begins. The firſt opening is large enough for three men conveniently to walk abreaſt. It continues of this bigneſs for 70 yards in a horizontal direction. Then it falls almoſt perpendicularly 50 yards, which may be deſcended by irregular ſteps from one to four feet diſtant from each other. It then continues 40 yards horizontally, at the end of which is another perpendicular deſcent, down which there are no ſteps. The cold here is intenſe. In ſpring and autumn, there are, once in about a week, exploſions from this cavern, which ſhake the ground for 16 miles round.

Lake Champlaine is next in ſize to Lake Ontario, and lies nearly eaſt from it, forming a part of the dividing line between the State of New York and the State of Vermont. It took its name from a French Governor, whoſe name was Champlaine, who was drowned in it. It was before called Corlaer's Lake. It is about 100 miles in length from north to ſouth, and in its broadeſt parts 12 or 14. It is well ſtored with fiſh, and the land on its borders and on the banks of its rivers is good. Crown Point and Ticonderoga are ſituated on the bank of this lake, near the ſouthern part of it.

Lake George lies to the ſouthward of Champlaine, and is a moſt clear, beautiful collection of water, 36 miles long, and from 1 to 7 miles wide. It emboſoms more than 200 iſlands, ſome ſay 365; very few of which are any thing more than barren rock, covered with heath, and a few cedar, ſpruce and hemlock trees and ſhrubs, and abundance of rattle-ſnakes. On each ſide it is ſkirted by prodigious mountains, from which large quantities of red cedar are every year carried to New York for ſhip timber. The lake is full of fiſhes, and ſome of the beſt kind; among which are the black or Oſwego baſs and large ſpeckled trouts. The water of this lake is about 100 feet above the level of Lake Champlaine. The portage between the two lakes is one mile and a half; but with a ſmall expenſe might be reduced to 60 yards; and with a ſufficient number of locks might be made navigable through for batteaux. This lake, in the French charts, is called Lake St Sacrament; and it is ſaid that the Roman Catholicks, in former times, were at the pains to procure this water for ſacramental uſes in all their churches in Canada: hence probably it derived its name.

The Miſſiſſippi receives the waters of the Ohio and Illinois, and their numerous branches from the eaſt; and of the Miſſouri and other rivers from the weſt. Theſe mighty ſtreams united are borne down with increaſing majeſty through vaſt foreſts and meadows, and diſcharged into the Gulf of Mexico. The great length and uncommon depth of this river, ſays Mr Hutchins, and the exceſſive muddineſs and ſalubrious quality of its waters, after its junction with the Miſſouri, are very ſingular (E). The direction of the channel is ſo crooked, that from New Orleans to the mouth of the Ohio, a diſtance which does not exceed four hundred and ſixty miles in a ſtrait line, is about eight hundred and fifty-ſix by water. It may be ſhortened at leaſt two hundred and fifty miles, by cutting acroſs eight or ten necks of land, ſome of which are not thirty yards wide. Charlevoix relates that in the year 1722, at Point Coupee, or Cut Point, the river made a great turn, and ſome Canadians, by deepening the channel of a ſmall brook, diverted the waters of the river into it. The impetuoſity of the ſtream was ſo violent, and the ſoil of ſo rich and looſe a quality, that in a ſhort time the point was entirely cut through, and travellers ſaved fourteen leagues of their voyage. The old bed has no water in it, the times of the periodical overflowing only excepted. The new channel has been ſince ſounded with a line of thirty fathoms without finding bottom. Several other points, of great extent, have, in like manner, been ſince cut off, and the river diverted into new channels.

In the ſpring floods the Miſſiſſippi is very high, and the current ſo ſtrong that it is with difficulty it can be aſcended; but this diſadvantage is remedied in ſome meaſure by eddies or counter-currents, which are generally found in the bends cloſe to the banks of the river, and aſſiſt the aſcending boats. The current at this ſeaſon deſcends at the rate of about five miles an hour. In autumn, when the waters are low, it does not run faſter than two miles, but it is rapid in ſuch parts of the river as have cluſters of iſlands, ſhoals and ſand-banks. The circumference

(E) In a half pint tumbler of this water has been found a ſediment of one inch of impalpable marle-like ſubſtance. It is notwithſtanding, extremely wholeſome and well taſted, and very cool in the hotteſt ſeaſons of the year; the rowers, who are there employed, drink of it when they are in the freeſt perſpiration, and never receive any bad effects from it. The inhabitants of New Orleans uſe no other water than that of the river, which, by being kept in jars, becomes perfectly clear.

cumference of many of thefe fhoals being feveral miles, the voyage is longer, and in fome parts more dangerous than in the fpring. The merchandife neceffary for the commerce of the upper fettlements on or near the Miffiffippi, is conveyed in the fpring and autumn in batteaux, rowed by eighteen or twenty men, and carrying about forty tons. From New Orleans to the Illinois, the voyage is commonly performed in eight or ten weeks. A prodigious number of iflands, fome of which are of great extent, interfperfe that mighty river. Its waters, after overflowing its banks below the river Ibberville on the eaft, and the river Rouge on the weft, never return within them again, there being many outlets or ftreams, by which they are conducted into the Bay of Mexico, more efpecially on the weft fide of the Miffiffippi, dividing the country into numerous iflands. Thefe fingularities diftinguifh it from every other known river in the world. Below the Ibberville, the land begins to be very low on both fides of the river, acrofs the country, and gradually declines as it approaches nearer to the fea. The ifland of New Orleans, and the lands oppofite, are to all appearance of no long date; for in digging ever fo little below the furface, you find water and great quantities of trees. The many beaches and breakers as well as inlets, which have arifen out of the channel fince 1650, at the feveral mouths of the river, are convincing proofs that this peninfula was wholly formed in the fame manner. And it is certain that when La Salle failed down the Miffiffippi to the fea, the opening of that river was very different from what it is at prefent.

The nearer you approach to the fea, this truth becomes more ftriking. The bars that crofs moft of thefe fmall channels, opened by the current, have been multiplied by means of the trees carried down with the ftreams; one of which, ftopped by its roots or branches in a fhallow part, is fufficient to obftruct the paffage of thoufands more, and to fix them at the fame place. Aftonifhing collections of trees are daily feen in paffing between the Balize and the Miffouri. No human force is fufficient to remove them, and the mud carried down by the river ferves to bind and cement them together. They are gradually covered, and every inundation not only extends their length and breadth, but adds another layer to their height. In lefs than ten years time, canes, fhrubs and aquatic timber grow on them, and form points and iflands, which forcibly fhift the bed of the river.

Nothing can be afferted with certainty, refpecting the length of this river. Its fource is not known, but fuppofed to be upwards of three thoufand miles from the fea as the river runs. We only know, that from St Anthony's Falls in lat. 45° it glides with a pleafant clear current, and receives many large and very extenfive tributary ftreams, before its junction with the Miffouri, without greatly increafing the breadth of the Miffiffippi, though they do its depth and rapidity. The muddy waters of the Miffouri difcolour the lower part of the river, till it empties into the Bay of Mexico. The Miffouri is a longer, broader, and deeper river than the Miffiffippi, and affords a more extenfive navigation; it is in fact the principal river, contributing more to the common ftream than does the Miffiffippi. It has been afcended by French traders about twelve or thirteen hundred miles, and from the depth of water, and breadth of the river at that diftance, it appeared to be navigable many miles further.

From the Miffouri river, to nearly oppofite the Ohio, the weftern bank of the Miffiffippi is (fome few places excepted) higher than the eaftern. From Mine-au-fer to the Ibberville, the eaftern bank is higher than the weftern, on which there is not a fingle difcernible rifing or eminence, the diftance of feven hundred and fifty miles. From the Ibberville to the fea, there are no eminences on either fide, though the eaftern bank appears rather the higheft of the two, as far as the Englifh turn. Thence the banks gradually diminifh in height to the mouths of the river, where they are but a few feet higher than the common furface of the water.

The flime which the annual floods of the river Miffiffippi leave on the furface of the adjacent fhores, may be compared with that of the Nile, which depofits a fimilar manure, and for many centuries paft has infured the fertility of Egypt. When its banks fhall have been cultivated, as the excellency of its foil and temperature of the climate deferves, its population will equal that of any other part of the world. The trade, wealth and power of America, may, at fome future period, depend, and perhaps centre upon the Miffiffippi. This alfo refembles the Nile in the number of its mouths, all iffuing into a fea that may be compared to the Mediterranean, which is bounded on the north and fouth by the two continents of Europe and Africa, as the Mexican Bay is by North and South America. The fmaller mouths of this river might be eafily ftopped up, by means of thofe floating trees with which the river, during the floods, is always covered. The whole force of the channel being united, the only opening then left would probably grow deep, and the bar be removed.

Whoever for a moment will caft his eye over a map of the town of New Orleans, and the immenfe country around it, and view its advantageous fituation, muft be convinced that it or fome place near it, muft in procefs of time become one of the greateft marts in the world.

The Falls of St Anthony, in about lat. 45°, received their name from Father Lewis Hennipin, a French miffionary, who travelled into thefe parts about the year 1680, and was the firft European ever feen by the natives. The whole river, which is more than 250 yards wide, falls perpendicularly about thirty feet, and forms a moft pleafing cataract. The rapids below, in the fpace of three hundred yards render the defcent confiderably greater; fo that when viewed at a diftance, they appear to be much higher than they really are. In the middle of the falls is a fmall ifland, about forty feet broad, and fomewhat longer, on which grow a few cragged hemlock and fpruce trees; and about half way between this ifland and the eaftern fhore is a rock, lying at the very edge of the fall, in an oblique pofition, five or fix feet broad, and thirty or forty long. Thefe falls are peculiarly fituated, as they are approachable without the leaft obftruction from any intervening hill or precipice, which cannot be faid of any other confiderable falls perhaps in the world. The country around is exceedingly beautiful. It is not an uninterrupted plain, where the eye finds no relief, but compofed of many gentle afcents, which, in the fpring and fummer, are covered with verdure, and interfperfed with little groves, that give a pleafing variety to the profpect.

 A little

A little diſtance below the falls, is a ſmall iſland of about an acre and an half, on which grow a great number of oak trees, almoſt all the branches of which, able to bear the weight, are, in the proper ſeaſon of the year, loaded with eagles neſts. Their inſtinctive wiſdom has taught them to chooſe this place, as it is ſecure on account of the rapids above, from the attacks of either man or beaſt.

From the beſt accounts that can be obtained from the Indians, we learn that four of the largeſt rivers on the continent of North America, among which are the St Lawrence, the Miſſiſſippi, and the Oregon, or the River of the Weſt, have their ſources in the ſame neighbourhood. The waters of three of them are ſaid to be within 30 miles of each other. If the above information is correct, it ſhews that theſe parts are the higheſt lands in North America: And it is an inſtance not to be parallelled in the other three quarters of the globe, that four rivers of ſuch magnitude ſhould take their riſe together, and each, after running ſeparate courſes, diſcharge their waters into different oceans, at the diſtance of more than two thouſand miles from their ſources. For in their paſſage from this ſpot to the bay of St Lawrence, eaſt; to the bay of Mexico, ſouth; and to the bay at the Straits of Annian, weſt, where the river Oregon is ſuppoſed to empty, each of them traverſes upwards of two thouſand miles.

The Ohio is a moſt beautiful river. Its current gentle, waters clear, and boſom ſmooth and unbroken by rocks and rapids, a ſingle inſtance only excepted. It is one quarter of a mile wide at Fort Pitt; five hundred yards at the mouth of the Great Kanhaway: 1200 yards at Louiſville; and the rapids, half a mile, in ſome few places below Louiſville: but its general breadth does not exceed 600 yards. In ſome places its width is not 400, and in one place particularly, far below the rapids, it is leſs than 300. Its breadth in no one place exceeds 1200 yards, and at its junction with the Miſſiſſippi, neither river is more than 900 yards wide.

Its length, as meaſured according to its meanders by Captain Hutchins, is 1188 miles.

In common winter and ſpring floods, it affords 30 or 40 feet water to Louiſville, 25 or 30 feet to La Tarte's Rapids, forty miles above the mouth of the Great Kanhaway, and a ſufficiency at all times for light batteaux and canoes to Fort Pitt. The Rapids are in latitude 38° 8′. The inundations of this river begin about the laſt of March, and ſubſide in July, although they frequently happen in other months; ſo that boats which carry 300 barrels of flour, from the Monongahela, or Yohogany, above Pittſburg, have ſeldom long to wait for water only. During theſe floods a firſt rate man-of-war may be carried from Louiſville to New Orleans, if the ſudden turns of the river and the ſtrength of its current will admit a ſafe ſteerage; and it is the opinion of Col. Morgan, who has had all the means of information, that a veſſel properly built for the ſea, to draw 12 feet water, when loaded, and carrying from 12 to 1600 barrels of flour, may be more eaſily, cheaply and ſafely navigated from Pittſburgh to the ſea, than thoſe now in uſe; and that this matter only requires one man of capacity and enterprize to aſcertain it. He obſerves that a veſſel intended to be rigged as a brigantine, ſnow, or ſhip, ſhould be double decked, take her maſts on deck, and be rowed to the Ibberville, below which are no iſlands, or to New Orleans, with 20 men, ſo as to afford reliefs of 10 and 10 in the night. Such a veſſel without the uſe of oars, he ſays would float to New Orleans, from Pittſburgh, in 20 times 24 hours. If this be ſo, what agreeable proſpects are preſented to our brethren and fellow citizens in the weſtern country.

The rapids at Louiſville deſcend about 10 feet in a length of a mile and a half. The bed of the river there is a ſolid rock, and is divided by an iſland into two branches, the ſouthern of which is about two hundred yards wide, but impaſſable in dry ſeaſons. The bed of the northern branch is worn into channels by the conſtant courſe of the water and attrition of the pebble-ſtones carried on with that, ſo as to be paſſable for batteaux through the greater part of the year. Yet it is thought that the ſouthern arm may be moſt eaſily opened for conſtant navigation. The riſe of the waters in theſe rapids does not exceed 20 or 25 feet. We have a fort, ſituated at the head of the falls. The ground on the ſouth ſide riſes very gradually.

At Fort Pitt the river Ohio looſes its name, branching into the Monongahela and Allegany.

The Monongahela is four hundred yards wide at its mouth. From thence is twelve or fifteen miles to the mouth of Yohogany, where it is 300 yards wide. Thence to Redſtone by water is 50 miles; by land 30. Then to the mouth of Cheat River, by water 40 miles; by land 28; the width continuing at 300 yards, and the navigation good for boats. Thence the width is about 200 yards to the weſtern fork, fifty miles higher, and the navigation is frequently interrupted by rapids; which, however, with a ſwell of two or three feet, become very paſſable for boats. It then admits light boats, except in dry ſeaſons, 65 miles further, to the head of Tygart's valley, preſenting only ſome ſmall rapids and falls of one or two feet perpendicular, and leſſening in its width to twenty yards. The weſtern fork is navigable in the winter ten or fifteen miles towards the northern of the Little Kanhaway, and will admit a good waggon road to it. The Yohogany is the principal branch of this river. It paſſes through the Laurel Mountain, about thirty miles from its mouth; is ſo far, from 300 to 150 yards wide, and the navigation much obſtructed in dry weather by rapids and ſhoals. In its paſſage through the mountain it makes very great falls, admitting no navigation for ten miles, to the Turkey Foot. Thence to the Great Croſſing, about twenty miles it is again navigable, except in dry ſeaſons, and at this place is two hundred yards wide. The ſources of this river are divided from thoſe of the Potomak by the Allegany Mountain. From the falls, where it interſects the Laurel Mountain, to Fort Cumberland, the head of the navigation on the Potomak, is 40 miles of very mountainous road. Will's Creek, at the mouth of which was Fort Cumberland, is 30 or 40 yards wide, but affords no navigation as yet. Cheat River, another conſiderable branch of the Monongahela, is 200 yards wide at its mouth, and 100 yards at the Dunkard's ſettlement, fifty miles higher. It is navigable for boats, except in dry ſeaſons. The boundary between Virginia and Pennſylvania croſſes it about three or four miles above its mouth.

The Allegany river affords navigation at all ſeaſons for light batteaux to Venango, at the mouth of French Creek,

Creek, where it is two hundred yards wide; and it is practised even to Le Bœuf, from whence there is a portage of fifteen miles and a half to Presque-Isle on Lake Erie.

The country watered by the Mississippi and its eastern branches, constitutes five-eighths of the United States; two of which five-eighths are occupied by the Ohio and its waters: the residuary streams, which run into the Gulf of Mexico, the Atlantic, and the St Lawrence, water the remaining three-eighths.

Before we quit the subject of the western waters, we will take a view of their principal connexions with the Atlantic. These are four; the Hudson's river, the Patomak, St Lawrence, and Mississippi. Down the last will pass all the heavy commodities. But the navigation through the Gulf of Mexico is so dangerous, and that up the Mississippi so difficult and tedious, that it is thought probable that European merchandize will not be conveyed through that channel. It is most likely that flour, timber, and other heavy articles will be floated on rafts, which will themselves be an article for sale, as well as their loading, the navigators returning by land, as at present. There will therefore be a competition between the Hudson, the Patomak, and the St Lawrence rivers, for the residue of the commerce of all the country westward of Lake Erie, on the waters of the lakes of the Ohio, and upper parts of Mississippi. To go to New York, that part of the trade which comes from the lakes or their waters, must first be brought into Lake Erie. Between Lake Superior and its waters, and Huron, are the Rapids of St Marie, which will permit boats to pass, but not larger vessels. Lakes Huron and Michigan afford communication with Lake Erie by vessels of eight feet draught. That part of the trade which comes from the waters of the Mississippi, must pass from them through some portage into the waters of the lakes. The portage from the Illinois river into a water of Michigan, is of one mile only. From the Wabash, Miama, Muskingum, or Allegany, are portages into the waters of Lake Erie, of from one to fifteen miles. When the commodities are brought into, and have passed through Lake Erie, there is between that and Ontario, an interruption by the Falls of Niagara, where the portage is of eight miles; and between Ontario and the Hudson's river are portages of the falls of Onondago, a little above Oswego, of a quarter of a mile; from Wood Creek to the Mohawks river two miles; at the little falls of the Mohawks river half a mile; and from Schenectady to Albany sixteen miles. Besides the increase of expense occasioned by frequent change of carriage, there is an increased risk of pillage produced by committing merchandize to a greater number of hands successively. The Patomak offers itself under the following circumstances: For the trade of the lakes and their waters westward of Lake Erie, when it shall have entered that lake, must coast along its southern shore, on account of the number and excellence or its harbours; the northern, though shortest, having few harbours, and these unsafe. Having reached Cayahoga, to proceed on to New York, it will have eight hundred and twenty-five miles and five portages; whereas it is but four hundred and twenty-five miles to Alexandria, its emporium on the Patomak, if it turns into the Cayahoga, and passes through that, Big Beaver, Ohio, Yohegany, (or Monongalia and Cheat) and Patomak, and there are but two portages; the first of which between Cayahoga and Beaver, may be removed by uniting the sources of these waters, which are lakes in the neighbourhood of each other, and in a champaign country; the other, from the waters of Ohio to Patomak, will be from fifteen to forty miles, according to the trouble which shall be taken to approach the two navigations. For the trade of the Ohio, or that which shall come into it from its own waters or the Mississippi, it is nearer through the Patomak to Alexandria than to New York, by five hundred and eighty miles, and it is interrupted by one portage only. There is another circumstance of difference too. The lakes themselves never freeze, but the communications between them freeze, and the Hudson's river is itself shut up by the ice three months in the year; whereas the channel to the Chesapeak leads directly into a warmer climate. The southern parts of it very rarely freeze at all, and whenever the northern do, it is so near the sources of the rivers, that the frequent floods, to which they are there liable, break up the ice immediately, so that vessels may pass through the whole winter, subject only to accidental and short delays. Add to all this, that in case of a war with our neighbours of Canada, or the Indians, the route to New York becomes a frontier through almost its whole length, and all commerce through it ceases from that moment. But the channel to New York is already known to practice; whereas, the upper waters of the Ohio and the Patomak, and the great falls of the latter, are yet to be cleared of their obstructions.

The route by St Lawrence is well known to be attended with many advantages, and with some disadvantages. But there is a fifth route, which the enlightened and enterprizing Pennsylvanians contemplate, which, if effected, will be the easiest, cheapest and surest passage from the lakes, and Ohio river, by means of the Susquehannah, and a canal from thence to Philadelphia. The latter part of this plan, viz. the canal between Susquehannah and the Schuylkill rivers, is now actually in execution. Should they accomplish their whole scheme, and they appear confident of success, Philadelphia, in all probability, will become, in some future period, one of the largest cities that has ever yet existed.

Particular descriptions of the other rivers in the United States, are given in the geographical accounts of those states, through which they respectively flow. One general observation respecting the rivers will, however, be naturally introduced here; and that is, that the entrance into almost all the rives, inlets and bays, from New-Hampshire to Georgia, are from south-east to north-west.

The coast of North America is indented with numerous bays, some of which are equal in size to any in the known world. Beginning at the northeasterly part of the continent, and proceeding southwesterly, you find among the *largest* of these bays, (for we do not pretend to a complete enumeration of them) first the Bay or Gulf of St Lawrence, which receives the waters of the river of the same name. Next are Chedebucto, and Chebucto Bays, in Nova-Scotia, the latter distinguished by the loss of a French fleet in a former war between France and Great Britain. The Bay of Fundy, between Nova-Scotia and New-Brunswick, is remarkable for its tides, which rise to the height of fifty or sixty feet,

United States.

feet, and flow so rapidly as to overtake animals which feed upon the shore. Passamaquoddy, Penobscot, Broad and Casco Bays, lie along the coast of the District of Maine. Massachusetts Bay spreads eastward of Boston, and is comprehended between Cape Ann on the north, and Cape Cod on the south. The points of Boston harbour are Nahant and Alderton points. Passing by Narraganset and other bays in the state of Rhode Island, you enter Long Island Sound, between Montauk Point and the main. This *Sound*, as it is called, is a kind of inland sea, from three to twenty-five miles broad, and about one hundred and forty miles long, extending the whole length of the island, and dividing it from Connecticut. It communicates with the ocean at both ends of Long Island, and affords a very safe and convenient inland navigation.

The celebrated strait, called *Hell Gate*, is near the west end of this Sound, about eight miles eastward of New-York city, and is remarkable for its whirlpools, which make a tremendous roaring at certain times of tide. These whirlpools are occasioned by the narrowness and crookedness of the pass, and a bed of rocks which extend quite across it; and not by the meeting of the tides from east to west, as has been conjectured, because they meet at Frogs Point, several miles above. A skilful pilot may, with safety, conduct a ship of any burden through this strait with the tide, or, at still water, with a fair wind (F).

Delaware Bay is sixty miles long, from the Cape to the entrance of the river Delaware at Bombay Hook, and so wide in some parts, as that a ship in the middle of it cannot be seen from the land. It opens into the Atlantic north-west and south-east, between Cape Henlopen on the right, and Cape May on the left. These Capes are eighteen or twenty miles apart.

The Chesapeak is a very spacious bay, 150 (some say 170) miles in length from north to south, and from 7 to 18 miles broad. It is generally as much as 9 fathoms deep, and affords many commodious harbours, and a safe and easy navigation. Its entrance, which is 12 miles wide, is nearly E. N. E. and S. S. W. between Cape Charles, lat. 37° 12′, and Cape Henry, lat. 37° in Virginia. It separates the eastern parts of Virginia and Maryland, leaving a small part of the former, and a large portion of the latter of these states on its eastern shore. It receives the waters of the Susquehannah, Patomak, Rappahannok, York and James Rivers, which are all large and navigable.

The tract of country belonging to the United States, is happily variegated with plains and mountains, hills and vallies. Some parts are rocky, particularly New England, the north parts of New York and New Jersey, and a broad space, including the several ridges of the long range of mountains which run south-westward through Pennsylvania, Virginia, North Carolina, and part of Georgia, dividing the waters which flow into the Atlantic, from those which fall into the Mississippi. In the parts east of the Allegany mountains, in the southern states, the country for several hundred miles in length, and sixty or seventy, and sometimes more, in breadth, is level and entirely free from stone. It has been a question, agitated by the curious, whether the extensive tract of low, flat country, which fronts the several states south of New York, and extends back to the hills, has remained in its present form and situation ever since the flood; or, whether it has been made by the particles of earth which have been washed down from the adjacent mountains, and by the accumulation of soil from the decay of vegetable substances; or, by earth washed out of the Bay of Mexico by the Gulf Stream, and lodged on the coast; or, by the recess of the ocean, occasioned by a change in some other parts of the earth; or, from other causes unknown to us. Several phenomena deserve consideration in forming an opinion on this question.

1. It is a fact well known to every person of observation who has lived in, or travelled through the southern states, that marine shells and other substances which are peculiar to the sea shore, are almost invariably found by digging eighteen or twenty feet below the surface of the earth. A gentleman of veracity told the author, that in sinking a well many miles from the sea, he found, at the depth of twenty feet, every appearance of a salt marsh, that is, marsh grass, marsh mud, and brackish water. In all this flat country, until you come to the hilly land, wherever you dig a well, you find the water, at a certain depth, fresh and tolerably good; but if you exceed that depth two or three feet, you come to a saltish or brackish water that is scarcely drinkable; and the earth dug up, resembles, in appearance and smell, that which is dug up on the edges of the salt marshes.

2. On and near the margin of the rivers are frequently found sand hills, which appear to have been drifted into ridges by the force of water. At the bottom of some of the banks in the rivers, fifteen or twenty feet below the surface of the earth, are washed out from the solid ground, logs, branches and leaves of trees; and the whole bank, from bottom to top, appears streaked with layers of logs, leaves and sand. These appearances are seen far up the rivers, from eighty to an hundred miles from the sea, where, when the rivers are low, the banks are from fifteen to twenty feet high. As you proceed down the rivers towards the sea, the banks decrease in height, but still are formed of layers of sand, leaves and logs, some of which are entirely sound, and appear to have been suddenly covered to a considerable depth.

3. It has been observed that the rivers in the southern states, frequently vary their channels; that the swamps and low grounds are constantly filling up; and that the land, in many places, annually infringes upon the ocean. It is an authenticated fact, that no longer ago than 1771, at Cape Lookout, on the coast of North Carolina, in about latitude 34° 50′, there was an excellent harbour, capacious enough to receive an hundred sail of shipping at a time, in a good depth of water. It is now entirely filled up, and is solid ground. Instances of this kind are frequent along the coast.

It is observable, likewise, that there is a gradual descent

(F) There is a tradition that Long Island and the adjacent Continent were, in former days, separated only by a small river, and that the aboriginal inhabitants of this place could step from rock to rock, and cross this "arm of the sea," as it may now be called, at *Hell Gate*. *Dr Mitchill.*

United States.

defcent of about eight hundred feet, by meafurement, from the foot of the mountains to the fea board. This defcent continues, as is demonftrated by foundings, far into the fea.

4. It is worthy of obfervation, that the foil on the banks of the rivers is proportionably coarfe or fine according to its diftance from the mountains. When you firft leave the mountains, and for a confiderable diftance, it is obfervable, that the foil is coarfe, with a large mixture of fand and fhining heavy particles. As you proceed toward the fea, the foil is lefs coarfe, and fo on, in proportion as you advance, the foil is finer and finer, until, finally, is depofited a foil fo fine, that it confolidates into perfect clay; but a clay of a peculiar quality, for a great part of it has intermixed with it reddifh ftreaks and veins, like a fpecies of *ochre*, brought probably from the *red lands* which lie up towards the mountains. This clay, when dug up and expofed to the weather, will diffolve into a fine mould, without the leaft mixture of fand or any gritty fubftance whatever. Now we know that running waters, when turbid, will depofit, firft, the coarfeft and heavieft particles, mediately, thofe of the feveral intermediate degrees of finenefs, and ultimately, thofe which are the moft light and fubtle; and fuch in fact is the general quality of the foil on the banks of the fouthern rivers.

5. It is a well known fact, that on the banks of Savannah river, about ninety miles from the fea, in a direct line, and one hundred and fifty or two hundred, as the river runs, there is a very remarkable collection of oyfter-fhells of an uncommon fize. They run in a north-eaft and fouth-weft direction, nearly parallel to the fea coaft, in three diftinct ridges, which together occupy a fpace of feven miles in breadth. The ridges commence at Savannah river, and have been traced as far fouth as the northern branches of the Alatamaha river. They are found in fuch quantities, as that the Indigo planters carry them away in large boat loads for the purpofe of making lime water, to be ufed in the manufacture of indigo. There are thoufands and thoufands of tons ftill remaining (G). The queftion is, how came they here? It cannot be fuppofed that they were carried by land. Neither is it probable that they were conveyed in canoes or boats to fuch a diftance from the place where oyfters are now found. The uncivilized natives, agreeably to their roving manner of living, would rather have removed to the fea fhore, than have been at fuch immenfe labour in procuring oyfters. Befides, the difficulties of conveying them would have been infurmountable. They would not only have had a ftrong current in the river againft them, an obftacle which would not have been eafily overcome by the Indians, who have ever had a great averfion to labour; but could they have furmounted this difficulty, oyfters conveyed fuch a diftance, either by land or water, in fo warm a climate, would have fpoiled on the paffage, and have become ufelefs. The circumftance of thefe fhells being found in fuch quantities, at fo great a diftance from the fea, can be rationally accounted for in no other way, than by fuppofing that the fea fhore was formerly near this bed of fhells, and that the ocean has fince, by the operation of certain caufes not yet fully inveftigated, receded. Thefe phenomena, as they cannot be otherwife accounted for, prove as far as it can be proved, that a great part of the flat country which fpreads eafterly of the Allegany mountains, had, in fome paft period, a fuperincumbent fea or water; but it is beyond the abilities of man to account for the change in a fatisfactory manner.

The tract of country eaft of Hudfon's river, comprehending part of the State of New York, the four New England States, and Vermont, is rough, hilly, and in fome parts mountainous. In all parts of the world, and particularly on this weftern continent, it is obfervable, that as you depart from the ocean or from a river, the land gradually rifes: and the height of land, in common, is about equally diftant from the water on either fide. The *Andes*, in South America, form the height of land between the Atlantic and Pacific Oceans. The Highlands between the diftrict of Maine and the Province of Lower Canada, divide the rivers which fall into the St Lawrence, north, and into the Atlantic, fouth. The Green Mountains, in Vermont, divide the waters which flow eafterly into Connecticut river from thofe which fall wefterly into Lake Champlaine, Lake George, and Hudfon's river.

Between the Atlantic, the Miffiffippi, and the Lakes, runs a long range of mountains, made up of a number of ridges. Thefe mountains extend north-eafterly and fouth-wefterly, nearly parallel to the fea coaft, about nine hundred miles in length, and from fixty to one hundred and fifty, and two hundred miles in breadth. Mr Evans obferves, with refpect to that part of thefe mountains which he travelled over, viz. in the back parts of Pennfylvania, that fcarcely one acre in ten is capable of culture. This, however, is not the cafe in all parts of this range. Numerous tracts of fine arable and

(G) " On the Georgia fide of the river, about 15 miles below Silver Bluff, the high road croffes a ridge of high fwelling hills of uncommon elevation, and perhaps 70 feet higher than the furface of the river. Thefe hills are from three feet below the common vegetative furface, to the depth of 20 or 30 feet, compofed entirely of foffil oyfter-fhells, internally of the colour and confiftency of clear white marble: They are of an incredible magnitude, generally 15 or 20 inches in length; from 6 to 8 wide, and from 2 to 4 in thicknefs, and their hollows fufficient to receive an ordinary man's foot. They appear all to have been opened before the period of petrifaction; a tranfmutation they feem evidently to have fuffered. They are undoubtedly very ancient, or perhaps antediluvian. The adjacent inhabitants burn them to lime, for building, for which purpofe they ferve very well; and would undoubtedly afford an excellent manure, when their lands require it, thefe hills now being remarkably fertile. The heaps of fhells lie upon a *ftratum* of yellowifh fand mould, of feveral feet in depth, upon a foundation of foft white rocks, that has the outward appearance of free ftone, but on ftrict examination is really a teftaceous concrete, or compofition of fand and pulverifed fea fhells. In fhort, this teftaceous rock approaches near in quality and appearance to the Bahama or Bermudian white rock." [*Bartram's Travels*, *p*. 318.]

United States.

and grazing land intervene between the ridges. The different ridges which compose this immense range of mountains have different names in different states.

As you advance from the Atlantic, the first ridge in Pennsylvania, Virginia, and North Carolina, is the Blue Ridge, or South Mountain, which is from one hundred and thirty to two hundred miles from the sea. Between this and the North Mountain spreads a large fertile vale; next lies the Allegany ridge; next beyond this is the Long Ridge, called the Laurel Mountains, in a spur of which, about latitude 36°, is a spring of water, fifty feet deep, very cold, and it is said, as blue as indigo. From these several ridges, proceed innumerable nameless branches or spurs. The Kittatinny Mountains run through the northern parts of New Jersey and Pennsylvania. All these ridges, except the Allegany, are separated by rivers, which appear to have forced their passages through solid rocks.

The principal ridge is the Allegany, which has been descriptively called the *back bone* of the United States. The general name for these mountains, taken collectively, seems not yet to have been determined. Mr Evans calls them the *Endless Mountains*: others have called them the *Appalachian* mountains, from a tribe of Indians, who live on a river which proceeds from this mountain, called the Appalachicola. But the most common name is the *Allegany Mountains*, so called, either from the principal ridge of the range, or from their running nearly parallel to the Allegany or Ohio River; which, from its head waters till it empties into the Mississippi, is known and called by the name of *Allegany River*, by the Seneca and other tribes of the Six Nations, who once inhabited it. These mountains are not confusedly scattered and broken, rising here and there into high peaks, overtopping each other, but stretch along in uniform ridges, scarcely half a mile high. They spread as you proceed south, and some of them terminate in high perpendicular bluffs. Others gradually subside into a level country, giving rise to the rivers which run southerly into the Gulf of Mexico.

They afford many curious phenomena, from which naturalists have deduced many theories of the earth; some of them have been very whimsical. Mr Evans supposes that the most obvious of the theories which have been formed of the earth is, that it was originally made out of the ruins of another. "Bones and shells which escaped the fate of softer animal substances, we find mixed with the old materials, and elegantly preserved in the loose stones and rocky bases of the highest of these hills." With deference, however, to Mr Evans's opinion, these appearances have been much more rationally accounted for by supposing the reality of the flood, of which Moses has given us an account. Mr Evans thinks this too great a miracle to obtain belief. But whether is it a greater miracle for the Creator to alter a globe of earth by a deluge, when made, or to create one new from the ruins of another? The former certainly is not less credible than the latter. "These mountains," says our author, "existed in their present elevated height before the deluge, but not so bare of soil as now." How Mr Evans came to be so circumstantially acquainted with these pretended facts, is difficult to determine, unless we suppose him to have been an Antediluvian, and to have surveyed them accurately before the convulsions of the deluge; and until we can be fully assured of this, we must be excused in not assenting to his opinion, and in adhering to the old philosophy of Moses and his advocates. We have every reason to believe that the primitive state of the earth was totally metamorphosed by the first convulsion of nature, at the time of the deluge; that *the fountains of the great deep were indeed broken up*, and that the various *strata* of the earth were dissevered, and thrown into every possible degree of confusion and disorder. Hence those vast piles of mountains which lift their craggy cliffs to the clouds, were probably thrown together from the floating ruins of the earth: And this conjecture is remarkably confirmed by the vast number of fossils and other marine *exuviæ* which are found imbedded on the tops of the mountains, in the interior parts of continents remote from the sea, in all parts of the world hitherto explored. The various circumstances attending these marine bodies, leave us to conclude, that they were actually generated, lived, and died in the very beds wherein they were found, and therefore these beds must have originally been at the bottom of the ocean, though now in many instances elevated several miles above its surface. Hence it has been supposed that mountains and continents were not primary productions of nature, but of a very distant period of time from the creation of the world; a time long enough for the *strata* to have acquired their greatest degree of cohesion and hardness; and for the testaceous matter of marine shells to become changed to a stony substance; for in the fissures of the lime-stone and other strata, fragments of the same shell have been frequently found adhering to each side of the cleft, in the very state in which they were originally broken; so that if the several parts were brought together, they would apparently tally with each other exactly. A very considerable time therefore must have elapsed between the chaotic state of the earth and the deluge, which agrees with the account of Moses, who makes it a little upwards of sixteen hundred years. These observations are intended to show, in one instance out of many others, the agreement between revelation and reason, between the account which Moses gives us of the creation and deluge, and the present appearances of nature.

In the United States are to be found every species of soil that the earth affords. In one part of them or another, they produce all the various kinds of fruits, grain, pulse and hortuline plants and roots, which are found in Europe, and have been thence transplanted to America. Besides these, a great variety of native, vegetable productions.

The natural history of the American States, is yet in its infancy. The productions of the southern states and of Canada, have not been well described by any one author, in a work professedly for that purpose; but are mostly intermixed with the productions of other parts of the world, in the large works of European Botanists. This renders it difficult to select them, and to give an accurate connected account of them. To remedy this inconvenience, and to rescue this country from the reproach of not having any authentic and scientific account of its Natural History, Rev. Dr Cutler, who has already examined nearly all the vegetables of New England, has for some time contemplated the publication of a botanical work of considerable magnitude, confined principally to the productions of the New England States.

States. Dr Barton, of Philadelphia, has been collecting materials for a work of a fimilar nature, to comprehend the middle and fouthern ftates; when finifhed, both together, will form a complete Natural Hiftory of the American States.

The birds of America, fays Catefby, generally exceed thofe of Europe in the beauty of their plumage, but are much inferior to them in the melody of their notes.

The middle ftates, including Virginia, appear to be the climates, in North America, where the greateft number and variety of birds of paffage celebrate their nuptials and rear their offspring, with which they annually return to more fouthern regions. Moft of our birds are birds of paffage from the fouthward. The eagle, the pheafant, grous and partridge of Pennfylvania, feveral fpecies of woodpeckers, the crow, blue jay, robin, marfh wren, feveral fpecies of fparrows or fnow birds, and the fwallow, are perhaps nearly all the land birds that continue the year round to the northward of Virginia.

Very few tribes of birds build or rear their young in the fouth or maritime parts of Virginia, in Carolina, Georgia and Florida; yet all thofe numerous tribes, particularly of the foft billed kind, which breed in Pennfylvania, pafs, in the fpring feafon, through thefe regions in a few weeks time, making but very fhort ftages by the way; and again, but few of them winter there on their return fouthwardly.

It is not known how far to the fouth they continue their route, during their abfence from the northern and middle ftates.

Among amphibious reptiles are the mud tortoife or turtle (Teftudo denticulata.) Speckled land tortoife (Teftudo carolina.) Great foft fhelled tortoife of Florida (Teftudo nafo cylindracea elongato, truncato. Bartram.) When full grown it weighs from 30 to 40 pounds, (fome fay 70 pounds) extremely fat and delicious food. Great land tortoife, called gopher; its upper fhell is about 18 inches long, and from 10 to 12 broad.—Found fouth of Savannah river.

Two fpecies of frefh water tortoifes inhabit the tide water rivers in the fouthern States; one is large, weighing from 10 to 12 pounds, the back fhell nearly of an oval form; the other fpecies fmall; but both are efteemed delicious food. The tortoifes of the northern ftates are of feveral fpecies, but have not been fcientifically defignated.

Of the frog kind there are many fpecies and in great numbers. Alfo of lizards, from the alligator to the fmall blue lizard.

Snakes are numerous, and of a great variety of kinds, fome of which, as the rattle fnake, are venomous and others not. They are not fo numerous nor fo venomous in the northern as in the fouthern ftates. In the latter, however, the inhabitants are furnifhed with a much greater variety of plants and herbs, which afford immediate relief to perfons bitten by thefe venomous creatures. It is an obfervation worthy of perpetual and grateful remembrance, that wherever venomous animals are found, the God of nature has kindly provided fufficient antidotes againft their poifon.

Of fifhes a vaft variety are found in the feas and rivers of the United States, from the whale down to the fmalleft fpecies.

A vaft variety of infects are found in the United States, of which fome catalogues have been publifhed by Dr Belknap and others.

United States.

According to the cenfus, taken by order of Congrefs, in 1790, the number of inhabitants in the United States of America, was three millions, nine hundred thirty thoufand, nearly. In this number none of the inhabitants of the Territory N. W. of the river Ohio, and but a part of the inhabitants of Tenneffee were included. Thefe added would undoubtedly have increafed the number to 3,950,000, at the period the cenfus was taken. According to the cenfus taken in 1800, the total number of inhabitants in the United States was five millions three hundred and five thoufand fix hundred and fixty fix, including eight hundred and ninety three thoufand fix hundred and five flaves.

The American Republic is compofed of almoft all nations, languages, characters and religions which Europe can furnifh; the greater part however, are defcended from Britain and Ireland.

The Americans, collected together from various countries, of different habits, formed under different governments, and of different languages, cuftoms, manners and religion, have not yet affimilated to that degree as to form a *national* character. We are yet an infant empire, rifing faft to maturity, with profpects of a vigorous and powerful manhood.

Until the revolution of 1783, Europeans were ftrangely ignorant of America and its inhabitants. They concluded that the new world *muft* be inferior to the old. The count de Buffon fuppofed that the animals in this country were uniformly lefs than in Europe, and thence concluded, that, "on this fide of the Atlantic there is a tendency in nature to diminifh the fize of her productions." The Abbe Raynal, in a former edition of his works, fuppofed this tendency or influence had its effect on the race of whites tranfplanted from Europe, and thence had the prefumption to affert that "America had not yet produced one good poet, one able mathematician, one man of genius in a fingle art or fcience." Had the Abbe been juftly informed, we prefume he would not have hazarded an affertion fo falfe, ungenerous and injurious to the genius and character of Americans. The fact is, the United States of America have produced their full proportion of genius in the fcience of war, in phyfics, aftronomy and mathematics; in mechanic arts, in government, in fifcal fcience, in divinity, in hiftory, in oratory, in poetry, in painting, in mufic, and the plaftic art. So many have diftinguifhed themfelves in fome of thefe branches of fcience, and fuch numbers are now living, that it would be an impracticable and invidious tafk to attempt an enumeration of them.

The two late important revolutions in America, which have been fcarcely exceeded in any former period of the world, viz. that of the declaration and eftablifhment of independence, and that of the adoption of a new and excellent form of government without blood fhed, have called to hiftoric fame many great and diftinguifhed characters who might otherwife have flept in oblivion.

One of the moft unamiable traits in the character of Americans, has been produced by the unjuftifiable practice of enflaving the negroes. The influence of flavery upon the morals, manners, induftry and liberties of a peo-

United States.

a people, is extremely pernicious. But under the federal government, from the meaſures already adopted, we have reaſon to indulge the pleaſing hope, that all ſlaves in the United States, will in time be emancipated, in a manner moſt conſiſtent with their own happineſs and the true intereſt of their proprietors.

In the middle and northern ſtates there are comparatively but few ſlaves; and of courſe there is leſs difficulty in giving them their freedom. In Maſſachuſetts alone, and we mention it to their diſtinguiſhed honour, there are NONE. Societies for the manumiſſion of ſlaves have been inſtituted in Philadelphia, New York, Providence and New Haven, and laws have been enacted in the New England ſtates, to accompliſh the ſame purpoſe. And it is with pleaſure we can aſſert, from the beſt information, that the condition of the negroes in the ſouthern ſtates is much ameliorated of late, and that no further importation is likely ever to take place. The Friends, (commonly called Quakers) have evinced the propriety of their name, by their goodneſs in originating, and their vigorous exertions in executing the truly humane and benevolent deſign of freeing the negroes. It is earneſtly hoped, however, that no meaſures will be adopted or purſued, which may hazard effects ſo ſhocking as have recently taken place in the Weſt India Iſlands, or which may produce a convulſion as unfavourable to the blacks as to their owners. The evil of ſlavery, if left pretty much to its own courſe, will beſt cure itſelf. At any rate, benevolence dictates that its abolition ſhould be gradual.

The Engliſh language is univerſally ſpoken in the United States, and in it buſineſs is tranſacted, and the records are kept. It is ſpoken with great purity, and pronounced with propriety in New England, by perſons of education; and, excepting ſome corruptions in pronunciation, by all ranks of people. In the middle and ſouthern ſtates, where they have had a great influx of foreigners, the language, in many inſtances, is corrupted, eſpecially in pronunciation. Attempts are making to introduce a uniformity of pronunciation throughout the ſtates, which for political as well as other reaſons, it is hoped will meet the approbation and encouragement of all literary and influential characters (H).

Intermingled with the Americans, are the Dutch, French, Germans, Swedes and Jews; all theſe retain, in a greater or leſs degree, their native language, in which they perform their public worſhip, converſe and tranſact their buſineſs with each other.

The time, however, is anticipated, at leaſt earneſtly wiſhed for, when all improper diſtinctions ſhall be aboliſhed; and when the language, manners, cuſtoms, political and religious ſentiments of the mixed maſs of people who inhabit the United States, ſhall have become ſo aſſimilated, as that all nominal and party diſtinctions ſhall be loſt in the general and honourable name of AMERICANS.

Until the fourth of July, 1776, the preſent United States were Britiſh colonies. On that memorable day, the Repreſentatives of the United States of America, in Congreſs aſſembled, made a ſolemn declaration, in which they aſſigned their reaſons for withdrawing their allegiance from the King of Great Britain. Appealing to the Supreme Judge of the world for the rectitude of their intentions, they did, in the name and by the authority of the good people of the colonies, ſolemnly publiſh and declare, That theſe United Colonies were, and of right ought to be FREE and INDEPENDENT States; that they were abſolved from all allegiance to the Britiſh crown, and that all political connexion between them and Great Britain was, and ought to be, totally diſſolved; and that as Free and Independent States, they had full power to levy war, conclude peace, contract alliances, eſtabliſh commerce, and do all other acts and things which Independent States may of right do. For the ſupport of this declaration, with a firm reliance on the protection of divine Providence, the delegates then in Congreſs, fifty-five in number, mutually pledged to each other their lives, their fortunes, and their ſacred honour.

At the ſame time they publiſhed Articles of Confederation and Perpetual Union between the ſtates, in which they took the ſtyle of "THE UNITED STATES OF AMERICA," and agreed, that each ſtate ſhould retain its ſovereignty, freedom, and independence, and every power, juriſdiction and right not expreſsly delegated to Congreſs by the confederation. By theſe articles, the Thirteen United States ſeverally entered into a firm league of friendſhip with each other for their common defence, the ſecurity of their liberties, and their mutual and general welfare, and bound themſelves to aſſiſt each other, againſt all force offered to, or attacks that might be made upon all, or any of them, on account of religion, ſovereignty, commerce or any other pretence whatever. But for the more convenient management of the general intereſts of the United States, it was determined, that Delegates ſhould be annually appointed, in ſuch manner as the Legiſlature of each ſtate ſhould direct, to meet in Congreſs the firſt Monday in November of every year, with a power reſerved to each ſtate to recal its delegates, or any of them, at any time within the year, and to ſend others in their ſtead for the remainder of the year. No ſtate was to be repreſented in Congreſs by leſs than two, or more than ſeven members; and no perſon could be a delegate for more than three years, in any term of ſix years, nor was any perſon, being a delegate, capable of holding any office under the United States, for which he, or any other for his benefit, ſhould receive

(H) "The northern and ſouthern ſtates differ widely in their cuſtoms, climate, produce, and in the general face of the country. The middle ſtates preſerve a medium in all theſe reſpects; they are neither ſo level and hot as the ſtates ſouth, nor ſo hilly and cold as thoſe north and eaſt. The inhabitants of the north are hardy, induſtrious, frugal, and in general well informed; thoſe of the ſouth, owing to the warmth of their climate, are more effeminate, indolent and luxurious. The fiſheries and commerce are the ſinews of the north; tobacco, rice, wheat and indigo of the ſouth. The northern ſtates are commodiouſly ſituated for trade and manufactures; the ſouthern to furniſh proviſions and raw materials; and the probability is, that the ſouthern ſtates will one day be ſupplied with northern manufactures, inſtead of European, and make their remittances in proviſions and raw materials." *MS. Journal of E. Watſon Eſq.*

ted tes. receive any ſalary, fees or emolument of any kind. In determining queſtions in Congreſs, each ſtate was to have one vote. Every ſtate was bound to abide by the determinations of Congreſs in all queſtions which were ſubmitted to them by the confederation. The articles of confederation were to be invariably obſerved by every ſtate, and the Union to be perpetual; nor was any alteration at any time hereafter to be made in any of the articles, unleſs ſuch alterations be agreed to in Congreſs, and be afterwards confirmed by the legiſlatures of every ſtate. The articles of confederation were ratified by Congreſs, July 9th, 1778.

Theſe articles of confederation, being found inadequate to the purpoſes of a federal government, for obvious reaſons, delegates were choſen in each of the United States, to meet and fix upon the neceſſary amendments. They accordingly met in convention at Philadelphia, in the ſummer of 1787, and agreed to propoſe the following Constitution for the conſideration of their conſtituents, and which we here inſert at length for the general information of the people, whom it concerns to be well acquainted with the nature of their own government.

We, the People of the United States, in order to form a more perfect union, eſtabliſh juſtice, inſure domeſtic tranquillity, provide for the common defence, promote the general welfare, and ſecure the bleſſings of liberty to ourſelves and our poſterity, do ordain and eſtabliſh this Conſtitution for the United States of America.

Art. 1. Sect. 1. All legiſlative powers herein granted ſhall be veſted in a Congreſs of the United States, which ſhall conſiſt of a Senate and Houſe of Repreſentatives.

Sect. 2. The Houſe of Repreſentatives ſhall be compoſed of members choſen every ſecond year by the people of the ſeveral ſtates, and the electors in each ſtate ſhall have the qualifications requiſite for electors of the moſt numerous branch of the ſtate legiſlature.

No perſon ſhall be a Repreſentative who ſhall not have attained the age of twenty-five years, and been ſeven years a citizen of the United States, and who ſhall not, when elected, be an inhabitant of that ſtate in which he ſhall be choſen.

Repreſentatives and direct taxes ſhall be apportioned among the ſeveral ſtates which may be included within this union, according to their reſpective numbers, which ſhall be determined by adding to the whole number of free perſons, including thoſe bound to ſervice for a term of years, and excluding Indians not taxed, three-fifths of all other perſons. The actual enumeration ſhall be made within three years after the firſt meeting of the Congreſs of the United States, and within every ſubſequent term of ten years, in ſuch manner as they ſhall by law direct. The number of repreſentatives ſhall not exceed one for every thirty thouſand, but each ſtate ſhall have at leaſt one repreſentative; and until ſuch enumeration ſhall be made, the ſtate of New Hampſhire ſhall be entitled to chooſe three, Maſſachuſetts eight, Rhode Iſland and Providence Plantations one, Connecticut five, New York ſix, New Jerſey four, Pennſylvania eight, Delaware one, Maryland ſix, Virginia ten, North Carolina five, South Carolina five, and Georgia three.

When vacancies happen in the repreſentation from any ſtate, the executive authority thereof ſhall iſſue writs of election to fill ſuch vacancies. United States.

The Houſe of Repreſentatives ſhall chooſe their Speaker and other officers; and ſhall have the ſole power of impeachment.

Sect. 3. The Senate of the United States ſhall be compoſed of two ſenators from each ſtate, choſen by the legiſlature thereof, for ſix years; and each ſenator ſhall have one vote.

Immediately after they ſhall be aſſembled, in conſequence of the firſt election, they ſhall be divided as equally as may be into three claſſes. The ſeats of the ſenators of the firſt claſs ſhall be vacated at the expiration of the ſecond year, of the ſecond claſs at the expiration of the fourth year, and of the third claſs at the expiration of the ſixth year, ſo that one third may be choſen every ſecond year; and if vacancies happen by reſignation, or otherwiſe, during the receſs of the legiſlature of any ſtate, the executive thereof may make temporary appointments until the next meeting of the legiſlature, which ſhall then fill ſuch vacancies.

No perſon ſhall be a ſenator who ſhall not have attained to the age of thirty years, and been nine years a citizen of the United States, and who ſhall not, when elected, be an inhabitant of that ſtate for which he ſhall be choſen.

The Vice Preſident of the United States ſhall be Preſident of the Senate, but ſhall have no vote, unleſs they be equally divided.

The Senate ſhall chooſe their other officers, and alſo a Preſident pro tempore in the abſence of the Vice Preſident, or when he ſhall exerciſe the office of Preſident of the United States.

The Senate ſhall have the ſole power to try all impeachments. When ſitting for that purpoſe, they ſhall be on oath or affirmation. When the Preſident of the United States is tried, the Chief Juſtice ſhall preſide; and no perſon ſhall be convicted without the concurrence of two-thirds of the members preſent.

Judgment in caſe of impeachment ſhall not extend further than to removal from office, and diſqualification to hold and enjoy any office of honour, truſt or profit under the United States; but the party convicted ſhall nevertheleſs be liable and ſubject to indictment, trial, judgment and puniſhment, according to law.

Sect. 4. The times, places and manner of holding elections for ſenators and repreſentatives, ſhall be preſcribed in each ſtate by the legiſlature thereof; but the Congreſs may at any time by law make or alter ſuch regulations, except as to the places of chooſing Senators.

The Congreſs ſhall aſſemble at leaſt once in every year, and ſuch meeting ſhall be on the firſt Monday in December, unleſs they ſhall by law appoint a different day.

Sect. 5. Each houſe ſhall be the judge of the elections, returns and qualifications of its own members, and a majority of each ſhall conſtitute a quorum to do buſineſs; but a ſmaller number may adjourn from day to day, and may be authoriſed to compel the attendance of abſent members, in ſuch manner, and under ſuch penalties as each houſe may provide.

Each houſe may determine the rules of its proceed-

United States.

ings, punifh its members for diforderly behaviour, and, with the concurrence of two-thirds, expel a member.

Each houfe fhall keep a journal of its proceedings, and from time to time publifh the fame, excepting fuch parts as may in their judgment require fecrecy; and the yeas and nays of the members of either houfe on any queftion, fhall, at the defire of one-fifth of thofe prefent, be entered on the journal.

Neither houfe, during the feffion of Congrefs, fhall, without the confent of the other, adjourn for more than three days, nor to any other place than that in which the two houfes fhall be fitting.

Sect. 6. The Senators and Reprefentatives fhall receive a compenfation for their fervices to be afcertained by law, and paid out of the treafury of the United States. They fhall in all cafes except treafon, felony and breach of the peace, be privileged from arreft during their attendance at the feffion of their refpective houfes, and in going to and returning from the fame; and for any fpeech or debate in either houfe, they fhall not be queftioned in any other place.

No Senator or Reprefentative fhall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which fhall have been created, or the emoluments whereof fhall have been increafed during fuch time; and no perfon holding any office under the United States, fhall be a member of either houfe during his continuance in office.

Sect. 7. All bills for raifing revenue fhall originate in the Houfe of Reprefentatives; but the Senate may propofe or concur with amendments as on other bills.

Every bill which fhall have paffed the Houfe of Reprefentatives and the Senate fhall, before it becomes a law, be prefented to the Prefident of the United States; if he approve, he fhall fign it, but if not, he fhall return it, with his objections, to that houfe in which it fhall have originated, who fhall enter the objections at large on their journal, and proceed to re-confider it. If, after fuch re-confideration, two-thirds of that houfe fhall agree to pafs the bill, it fhall be fent, together with the objections to the other houfe, by which it fhall likewife be re-confidered, and if approved by two-thirds of that houfe it fhall become a law. But in all fuch cafes the votes of both houfes fhall be determined by yeas and nays, and the names of the perfons voting for and againft the bill fhall be entered on the journal of each houfe refpectively. If any bill fhall not be returned by the Prefident within ten days, (Sundays excepted) after it fhall have been prefented to him, the fame fhall be a law, in like manner as if he had figned it, unlefs the Congrefs, by their adjournment, prevent its return, in which cafe it fhall not be a law.

Every order, refolution, or vote, to which the concurrence of the Senate and Houfe of Reprefentatives may be neceffary (except on a queftion of adjournment) fhall be prefented to the Prefident of the United States; and before the fame fhall take effect, fhall be approved by him, or, being difapproved by him, fhall be re-paffed by two-thirds of the Senate and Houfe of Reprefentatives, according to the rules and limitations prefcribed in the cafe of a bill.

Sect. 8. The Congrefs fhall have power

To lay and collect taxes, duties, impofts and excifes; to pay the debts and provide for the common defence and general welfare of the United States; but all duties, impofts and excifes fhall be uniform throughout the United States;

To borrow money on the credit of the United States:

To regulate commerce with foreign nations, and among the feveral ftates, and with the Indian tribes;

To eftablifh an uniform rule of naturalization, and uniform laws on the fubject of bankruptcies throughout the United States;

To coin money, regulate the value thereof, and of foreign coin, and fix the ftandard of weights and meafures;

To provide for the punifhment of counterfeiting the fecurities and current coin of the United States;

To eftablifh poft offices and poft roads;

To promote the progrefs of fcience and ufeful arts, by fecuring for limited times, to authors and inventors, the exclufive right to their refpective writings and difcoveries;

To conftitute tribunals inferior to the fupreme court;

To define and punifh piracies and felonies committed on the high feas, and offences againft the law of nations;

To declare war, grant letters of marque and reprifal, and make rules concerning captures on land and water;

To raife and fupport armies, but no appropriation of money to that ufe fhall be for a longer term than two years;

To provide and maintain a navy;

To make rules for the government and regulation of the land and naval forces;

To provide for calling forth the militia to execute the laws of the union, fupprefs infurrections, and repel invafions;

To provide for organizing, arming, and difciplining the militia, and for governing fuch part of them as may be employed in the fervice of the United States, referving to the ftates refpectively the appointment of the officers, and the authority of training the militia according to the difcipline prefcribed by Congrefs;

To exercife exclufive legiflation in all cafes whatfoever over fuch diftrict (not exceeding ten miles fquare) as may by ceffion of particular ftates, and the acceptance of Congrefs, become the feat of the government of the United States, and to exercife like authority over all places purchafed by the confent of the legiflature of the ftate in which the fame fhall be, for the erection of forts, magazines, arfenals, dockyards, and other needful buildings:—And

To make all laws which fhall be neceffary and proper for carrying into execution the foregoing powers, and all other powers vefted by this conftitution in the government of the United States, or in any department or officer thereof.

Sect. 9. The migration or importation of fuch perfons as any of the ftates now exifting fhall think proper to admit, fhall not be prohibited by the Congrefs prior to the year one thoufand eight hundred and eight, but a tax or duty may be impofed on fuch importation, not exceeding ten dollars for each perfon.

The privilege of the writ of habeas corpus fhall not be fufpended, unlefs when in cafes of rebellion or invafion the public fafety may require it.

No bill of attainder or ex poft facto law fhall be paffed.

No

United States.

No capitation, or other direct tax, ſhall be laid, unleſs in proportion to the cenſus or enumeration herein before directed to be taken.

No tax or duty ſhall be laid on articles exported from any ſtate.—

No preference ſhall be given by any regulation of commerce or revenue to the ports of one ſtate over thoſe of another; nor ſhall veſſels bound to or from one ſtate, be obliged to enter, clear, or pay duties in another.

No money ſhall be drawn from the treaſury, but in conſequence of appropriations made by law; and a regular ſtatement and account of the receipts and expenditures of all public money ſhall be publiſhed from time to time.

No title of nobility ſhall be granted by the United States; and no perſon holding any office of profit or truſt under them, ſhall, without the conſent of Congreſs, accept of any preſent, emolument, office or title of any kind whatever, from any king, prince or foreign ſtate.

Sect. 10. No ſtate ſhall enter into any treaty, alliance or confederation; grant letters of marque and repriſal; coin money; emit bills of credit; make any thing but gold and ſilver coin a tender in payment of debts; paſs any bill of attainder, ex poſt facto law, or law impairing the obligation of contracts, or grant any title of nobility.

No ſtate ſhall, without the conſent of Congreſs, lay any impoſt or duties on imports or exports, except what may be abſolutely neceſſary for executing its inſpection laws; and the net produce of all duties and impoſts, laid by any ſtate on imports or exports, ſhall be for the uſe of the treaſury of the United States; and all ſuch laws ſhall be ſubject to the reviſion and control of the Congreſs. No ſtate ſhall, without the conſent of Congreſs, lay any duty of tonnage, keep troops, or ſhips of war, in time of peace, enter into any agreement or compact with another ſtate, or with a foreign power, or engage in war, unleſs actually invaded, or in ſuch imminent danger as will not admit of delay.

Art. 2. Sect. 1. The executive power ſhall be veſted in a Preſident of the United States of America. He ſhall hold his office during the term of four years, and, together with the Vice Preſident, choſen for the ſame term, be elected as follows:

Each ſtate ſhall appoint, in ſuch manner as the legiſlature thereof may direct, a number of electors, equal to the whole number of Senators and Repreſentatives to which the ſtate may be entitled in the Congreſs; but no Senator or Repreſentative, or perſon holding an office of truſt or profit under the United States, ſhall be appointed an elector.

The electors ſhall meet in their reſpective ſtates, and vote by ballot for two perſons, of whom one at leaſt ſhall not be an inhabitant of the ſame ſtate with themſelves. And they ſhall make a liſt of all the perſons voted for, and of the number of votes for each; which liſt they ſhall ſign and certify, and tranſmit, ſealed, to the ſeat of the government of the United States, directed to the Preſident of the Senate. The Preſident of the Senate ſhall, in the preſence of the Senate and Houſe of Repreſentatives, open all the certificates, and the votes ſhall then be counted. The perſon having the greateſt number of votes ſhall be the Preſident, if ſuch number be a majority of the whole number of electors appointed; and if there be more than one who have ſuch majority, and have an equal number of votes, then the Houſe of Repreſentatives ſhall immediately chooſe by ballot one of them for Preſident; and if no perſon have a majority, then from the five higheſt on the liſt, the ſaid Houſe ſhall in like manner chooſe the Preſident. But in chooſing the Preſident, the votes ſhall be taken by ſtates, the repreſentation from each ſtate having one vote; a quorum for this purpoſe ſhall conſiſt of a member or members from two-thirds of the ſtates, and a majority of all the ſtates ſhall be neceſſary to a choice. In every caſe, after the choice of the Preſident, the perſon having the greateſt number of votes of the electors ſhall be the Vice Preſident. But if there ſhould remain two or more who have equal votes, the Senate ſhall chooſe from them by ballot the Vice Preſident.

The Congreſs may determine the time of chooſing the electors, and the day on which they ſhall give their votes; which day ſhall be the ſame throughout the United States.

No perſon, except a natural born citizen, or a citizen of the United States at the time of the adoption of this conſtitution, ſhall be eligible to the office of Preſident; neither ſhall any perſon be eligible to that office who ſhall not have attained to the age of thirty-five years, and been fourteen years a reſident within the United States.

In caſe of the removal of the Preſident from office, or of his death, reſignation, or inability to diſcharge the powers and duties of the ſaid office, the ſame ſhall devolve on the Vice Preſident, and the Congreſs may by law provide for the caſe of removal, death, reſignation or inability, both of the Preſident and Vice Preſident, declaring what officer ſhall then act as Preſident, and ſuch officer ſhall act accordingly, until the diſability be removed, or a Preſident ſhall be elected.

The Preſident ſhall, at ſtated times, receive for his ſervices a compenſation, which ſhall neither be increaſed or diminiſhed during the period for which he ſhall have been elected, and he ſhall not receive within that period any other emolument from the United States, or any of them.

Before he enter on the execution of his office, he ſhall take the following oath or affirmation.

"I do ſolemnly ſwear (or affirm) that I will faithfully execute the office of Preſident of the United States, and will, to the beſt of my ability, preſerve, protect, and defend the conſtitution of the United States."

Sect. 2. The Preſident ſhall be commander in chief of the army and navy of the United States and of the militia of the ſeveral ſtates, when called into the actual ſervice of the United States; he may require the opinion, in writing, of the principal officer in each of the executive departments, upon any ſubject relating to the duties of their reſpective offices, and he ſhall have power to grant reprieves and pardons for offences againſt the United States, except in caſes of impeachment.

He ſhall have power, by and with the advice and conſent of the Senate, to make treaties, provided two-thirds of the ſenators preſent concur; and he ſhall nominate, and by and with the advice and conſent of the Senate, ſhall appoint ambaſſadors, other public miniſters and conſuls, judges of the ſupreme court, and all other officers of the United States, whoſe appointments are not herein otherwiſe provided for, and which ſhall be eſtabliſhed

United States.

lished by law. But the Congress may by law vest the appointment of such inferior officers as they think proper in the President alone, in the courts of law, or in the heads of departments.

The President shall have power to fill up all vacancies that may happen during the recess of the Senate, by granting commissions which shall expire at the end of their next session.

Sect. 3. He shall from time to time give to the Congress information of the state of the Union, and recommend to their consideration such measures as he shall judge necessary and expedient; he may, on extraordinary occasions, convene both houses, or either of them, and in case of disagreement between them, with respect to the time of adjournment, he may adjourn them to such time as he shall think proper; he shall receive ambassadors and other public ministers; he shall take care that the laws be faithfully executed, and shall commission all the officers of the United States.

Sect. 4. The President, Vice President, and all civil officers of the United States, shall be removed from office on impeachment for, and conviction of, treason, bribery, or other high crimes and misdemeanors.

Art. 3. Sect. 1. The Judicial power of the United States shall be vested in one supreme court, and in such inferior courts as the Congress may from time to time ordain and establish. The Judges, both of the supreme and inferior courts, shall hold their offices during good behaviour, and shall, at stated times, receive for their services a compensation, which shall not be diminished during their continuance in office.

Sect. 2. The judicial power shall extend to all cases, in law and equity, arising under this constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers and consuls; to all cases of admiralty and maritime jurisdiction; to controversies to which the United States shall be a party; to controversies between two or more states, between a state and citizens of another state, between citizens of different states, between citizens of the same state claiming lands under grants of different states, and between a state, or the citizens thereof, and foreign states, citizens or subjects.

In all cases affecting ambassadors, other public ministers and consuls, and those in which a state shall be a party, the supreme court shall have original jurisdiction. In all the other cases before mentioned, the supreme court shall have appellate jurisdiction, both as to law and fact, with such exceptions, and under such regulations as the Congress shall make.

The trial of all crimes, except in cases of impeachment, shall be by jury; and such trials shall be held in the state where the said crime shall have been committed; but when not committed within any state, the trial shall be at such place or places as the Congress may by law have directed.

Sect. 3. Treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort. No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court.

The Congress shall have power to declare the punishment of treason, but no attainder of treason shall work corruption of blood, or forfeiture, except during the life of the person attainted.

Art. 4. Sect. 1. Full faith and credit shall be given in each state to the public acts, records, and judicial proceedings of every other state. And the Congress may by general laws prescribe the manner in which such acts, records and proceedings shall be proved, and the effect thereof.

Sect. 2. The citizens of each state shall be entitled to all privileges and immunities of citizens in the several states.

A person charged in any state with treason, felony, or other crime, who shall flee from justice, and be found in another state, shall, on demand of the executive authority of the state from which he fled, be delivered up, to be removed to the state having jurisdiction of the crime.

No person held to service or labour in one state, under the laws thereof, escaping into another, shall in consequence of any law or regulation therein, be discharged from such service or labour, but shall be delivered up on claim of the party to whom such service or labour may be due.

Sect. 3. New States may be admitted by the Congress into this union, but no new state shall be formed or erected within the jurisdiction of any other state; nor any state be formed by the junction of two or more states, or parts of states, without the consent of the legislatures of the states concerned as well as of the Congress.

The Congress shall have power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States; and nothing in this constitution shall be so construed as to prejudice any claims of the United States, or of any particular state.

Sect. 4. The United States shall guarantee to every state in this union a republican form of government, and shall protect each of them against invasion; and on application of the legislature, or of the executive (when the legislature cannot be convened) against domestic violence.

Art. 5. The Congress, whenever two-thirds of both Houses shall deem it necessary, shall propose amendments to this constitution, or, on the application of the legislatures of two-thirds of the several states, shall call a convention for proposing amendments, which in either case, shall be valid to all intents and purposes, as part of this constitution, when ratified by the legislatures of three-fourths of the several states, or by Conventions in three-fourths thereof, as the one or the other mode of ratification may be proposed by the Congress: Provided, that no amendment which may be made prior to the year one thousand eight hundred and eight shall in any manner affect the first and fourth clauses in the ninth section of the first article; and that no state, without its consent, shall be deprived of its equal suffrage in the Senate.

Art. 6. All debts contracted and engagements entered into, before the adoption of this constitution, shall be as valid against the United States under this constitution, as under the confederation.

This constitution, and the laws of the United States which shall be made in pursuance thereof; and all treaties made, or which shall be made, under the authority of

United States.

of the United States, ſhall be the ſupreme law of the land; and the judges in every ſtate ſhall be bound thereby, any thing in the conſtitution or laws of any ſtate to the contrary notwithſtanding.

The Senators and Repreſentatives before mentioned, and the members of the ſeveral State Legiſlatures, and all Executive and Judicial officers, both of the United States and of the ſeveral ſtates, ſhall be bound by oath or affirmation, to ſupport this conſtitution; but no religious teſt ſhall ever be required as a qualification to any office or public truſt under the United States.

Art. 7. The ratification of the conventions of nine ſtates, ſhall be ſufficient for the eſtabliſhment of this conſtitution between the ſtates ſo ratifying the ſame.

DONE in Convention, by the unanimous conſent of the ſtates preſent, the ſeventeenth day of September, in the year of our Lord one thouſand ſeven hundred and eighty-ſeven, and of the Independence of the United States of America, the Twelfth. In Witneſs whereof, we have hereunto ſubſcribed our names.

GEORGE WASHINGTON, PRESIDENT.

Signed alſo by all the Delegates which were preſent from twelve ſtates.

Atteſt. WILLIAM JACKSON, SECRETARY.

The foregoing Conſtitution has ſince been adopted by all the ſtates in the Union, as is hereafter more particularly mentioned.

The Conventions of a number of the ſtates having at the time of their adopting the Conſtitution expreſſed a deſire, in order to prevent miſconſtruction or abuſe of its powers, that further declaratory and reſtrictive clauſes ſhould be added: And as extending the ground of public confidence in the government will beſt enſure the beneficent ends of its inſtitution,

Reſolved by the Senate and Houſe of Repreſentatives of the United States of America in Congreſs aſſembled, two-thirds of both houſes concurring, That the following articles be propoſed to the legiſlatures of the ſeveral ſtates, as amendments to the Conſtitution of the United States, all or any of which articles, when ratified by three-fourths of the ſaid legiſlatures, to be valid to all intents and purpoſes, as part of the ſaid conſtitution, viz.

Articles in addition to, and amendment of, the Conſtitution of the United States of America, propoſed by Congreſs, and ratified by the Legiſlatures of the ſeveral ſtates, purſuant to the fifth Article of the original conſtitution.

Art. 1. After the firſt enumeration required by the firſt article of the Conſtitution, there ſhall be one Repreſentative for every thirty thouſand, until the number ſhall amount to one hundred, after which the proportion ſhall be ſo regulated by Congreſs, that there ſhall be not leſs than one hundred Repreſentatives, nor leſs then one Repreſentative for every forty thouſand perſons, until the number of Repreſentatives ſhall amount to two hundred, after which the proportion ſhall be ſo regulated by Congreſs, that there ſhall not be leſs than two hundred Repreſentatives, nor more than one Repreſentative for every fifty thouſand perſons.

Art. 2. No law varying the compenſation for the ſervices of the Senators and Repreſentatives ſhall take effect, until an election of Repreſentatives ſhall have intervened.

Art. 3. Congreſs ſhall make no law reſpecting an eſtabliſhment of religion, or prohibiting the free exerciſe thereof; or abridging the freedom of ſpeech, or of the preſs; or the right of the people peaceably to aſſemble, and to petition the government for a redreſs of grievances.

Art. 4. A well regulated militia being neceſſary to the ſecurity of a free ſtate, the right of the people to keep and bear arms, ſhall not be infringed.

Art. 5. No ſoldier ſhall in time of peace be quartered in any houſe without the conſent of the owner, nor in time of war, but in a manner to be preſcribed by law.

Art. 6. The right of the people to be ſecure in their perſons, houſes, papers and effects againſt unreaſonable ſearches and ſeizures, ſhall not be violated; and no warrants ſhall iſſue, but upon probable cauſe, ſupported by oath or affirmation, and particularly deſcribing the place to be ſearched, and the perſons or things to be ſeized.

Art. 7. No perſon ſhall be held to anſwer for a capital, or otherwiſe infamous crime, unleſs on a preſentment or indictment of a grand jury, except in caſes ariſing in the land or naval forces, or in the militia when in actual ſervice in time of war or public danger: nor ſhall any perſon be ſubject for the ſame offence to be twice put in jeopardy of life or limb; nor ſhall be compelled in any criminal caſe to be a witneſs againſt himſelf, nor be deprived of life, liberty or property, without due proceſs of law; nor ſhall private property be taken for public uſe without juſt compenſation.

Art. 8. In all criminal proſecutions the accuſed ſhall enjoy the right to a ſpeedy and public trial, by an impartial jury of the ſtate and diſtrict wherein the crime ſhall have been committed, which diſtrict ſhall have been previouſly aſcertained by law, and to be informed of the nature and cauſe of the accuſation; to be confronted with the witneſſes againſt him; to have compulſory proceſs for obtaining witneſſes in his favour, and to have the aſſiſtance of counſel for his defence.

Art. 9. In ſuits at common law, where the value in controverſy ſhall exceed twenty dollars, the right of trial by jury ſhall be preſerved, and no fact, tried by a jury, ſhall be otherwiſe re-examined in any court of the United States, than according to the rules of the common law.

Art. 10. Exceſſive bail ſhall not be required, nor exceſſive fines impoſed, nor cruel and unuſual puniſhments inflicted.

Art. 11. The enumeration in the Conſtitution, of certain rights, ſhall not be conſtrued to deny or diſparage others retained by the people.

Art. 12. The powers not delegated to the United States by the Conſtitution, nor prohibited by it to the States, are reſerved to the States reſpectively, or to the people.

How many of the foregoing articles have become parts of the Conſtitution, by conſent of three-fourths of the States, is not known to the writer. The following ſtates in 1796, had ratified all of them, viz. Maryland, North Carolina, South Carolina, New York, Virginia and Vermont. New Hampſhire, New Jerſey and Pennſylvania had rejected the ſecond article, and Delaware the firſt. Other amendments have ſince been propoſed.

The *Society of the Cincinnati* was inſtituted immediately on the cloſe of the war in 1783. At their firſt general meeting in Philadelphia, in May, 1784, they altered and amended the original inſtitution, and reduced

United States.

duced it to its present form. They denominated themselves, "*The Society of the Cincinnati*," from the high veneration they possessed for the character of that illustrious Roman, *Lucius Quintus Cincinnatus*.

The persons who constitute this society, are all the commissioned and brevet officers of the army and navy of the United States, who served three years, and who left the service with reputation; all officers who were in actual service at the conclusion of the war; all the principal staff officers of the continental army; and the officers who have been deranged by the several resolutions of Congress, upon the different reforms of the army.

The motives which originally induced the officers of the American army to form themselves into a society of friends, are summed up in a masterly manner, in their circular letter. "Having," say they, "lived in the strictest habits of amity through the various stages of a war, unparalleled in many of its circumstances; having seen the objects for which we have contended, happily attained; in the moment of triumph and separation, when we were about to act the last pleasing, melancholy scene in our military drama; pleasing, because we were to leave our country possessed of independence and peace; melancholy, because we were to part, perhaps never to meet again; while every breast was penetrated with feelings which can be more easily conceived than described; while every little act of tenderness recurred fresh to the recollection, it was impossible not to wish our friendships should be continued, it was extremely natural to desire they might be perpetuated by our posterity to the remotest ages. With these impressions, and with such sentiments, we candidly confess we signed the institution. We knew our motives were irreproachable."

They rest their institution upon the two great pillars of FRIENDSHIP and CHARITY. Their benevolent intentions are, to diffuse comfort and support to any of their unfortunate companions who have seen better days, and have merited a milder fate; to wipe the tear from the eye of the widow, who must have been consigned, with her helpless infants, to indigence and wretchedness, but for this charitable institution; to succour the fatherless; to rescue the female orphan from destruction; and to enable the son to emulate the virtues of the father. "Let us, then," they conclude, "prosecute with ardor what we have instituted in sincerity; let Heaven and our own consciences approve our conduct; let our actions be our best comment on our words; and let us leave a lesson to posterity, That the glory of Soldiers cannot be completed, without acting well the part of Citizens."

The Society have an order, viz. a Bald Eagle of gold, bearing on its breast the emblems described as follows:

The principal figure is CINCINNATUS; three senators presenting him with a sword and other military ensigns: On a field in the back ground, his wife standing at the door of their cottage; near it a plough and other instruments of husbandry. Round the whole, *omnia reliquit servare rempublicam*. On the reverse, the sun rising, a city with open gates, and vessels entering the port; fame crowning *Cincinnatus* with a wreath, inscribed, *virtutis premium*. Below, hands joining, supporting a heart; with the motto, *esto perpetua*. Round the whole, *Societas Cincinnatorum, instituta*, A. D. 1783.

The three important objects of attention in the United States, are agriculture, commerce and manufactures. The richness of the soil, which amply rewards the industrious husbandman; the temperature of the climate, which admits of steady labour; the cheapness of land, which tempts the foreigner from his native home; and the extensive tracts of unsettled lands, leads us to fix on agriculture as the present great leading interest of this country. This furnishes outward cargoes not only for all our own ships, but for those also which foreign nations send to our ports; or in other words it pays all our importations; it supplies a great part of the clothing of the inhabitants, and food for them and their cattle. What is consumed at home, including the materials for manufacturing, has been estimated at four or five times the value of what is exported.

The number of people employed in agriculture, is at least three parts in four of the inhabitants of the United States. It follows of course that they form the body of the militia, who are the bulwark of the nation. The value of the property occupied by agriculture, is many times greater than the property employed in every other way. The settlement of waste lands, the subdivision of farms, and the numerous improvements in husbandry, annually increase the preeminence of the agricultural interest. The resources we derive from it, are at all times certain and indispensably necessary. Besides, the rural life promotes health, by its active nature; and morality, by keeping people from the luxuries and vices of the populous towns. In short, agriculture is the spring of our commerce, and the parent of our manufactures. It is friendly, nay it is necessary, to the existence of a republican form of government.

The vast extent of sea coast, which spreads before these confederated states; (1) the number of excellent harbours and sea-port towns; the numerous creeks and immense bays, which indent the coast; and the rivers, lakes and canals, which peninsulate the whole country; added to its agricultural advantages and improvements, give this part o the world superior advantages for trade. Our commerce, including our exports, imports, shipping, manufactures and fisheries, may properly be considered

(1) When the extent of America is considered, boldly fronting the old world, blessed with every climate, capable of every production, abounding with the best harbours and rivers on the globe, and already overspread with five millions of souls, mostly descendants of Englishmen, inheriting all their ancient enthusiasm for liberty, and enterprizing almost to a fault; what may be expected from such a people in such a country? The partial hand of nature has laid off America upon a much larger scale than any other part of the world. Hills in America are mountains in Europe, brooks are rivers, and ponds are swelled into lakes. In short, the map of the world cannot exhibit a country uniting so many natural advantages, so pleasingly diversified, and that offers such abundant and easy resources to agriculture, commerce and manufactures.

"In contemplating *future America*, the mind is lost in the din of cities, in harbours and rivers clouded with sails, and in the immensity of her population." [*MS. Journal of Elkanah Watson, Esq.*]

confidered as forming one intereft. This has been confidered as the great object, and the moft important intereft of the New England States.

The late war, which brought about our feparation from Great Britain, threw our commercial affairs into great confufion. The powers of the old confederation were unequal to the complete execution of any meafures, calculated effectually to recover them from their deranged fituation. Through want of power in the old Congrefs to collect a revenue for the difcharge of our foreign and domeftic debt, our credit was deftroyed, and trade of confequence greatly embarraffed. Each ftate, in her defultory regulations of trade, regarded her own intereft, while that of the union was neglected. And fo different were the interefts of the feveral ftates, that their laws refpecting trade often clafhed with each other, and were productive of unhappy confequences. The large commercial ftates had it in their power to opprefs their neighbours; and in fome inftances this power was directly or indirectly exercifed. Thefe impolitic and unjuftifiable regulations, formed on the impreffion of the moment, and proceeding from no uniform or permanent principles, excited unhappy jealoufies between the clafhing ftates, and occafioned frequent ftagnations in their trade, and in fome inftances, a fecrecy in their commercial policy. But the wife meafures which have been adopted by Congrefs, under the prefent government, have extricated us from thefe embarraffments, and put a new and pleafing face upon our affairs. Invefted with the adequate powers, Congrefs have formed a fyftem of commercial regulations, which has placed our commerce on a refpectable, uniform and intelligible footing, adapted to promote the general interefts of the union, with the fmalleft injury to the individual ftates.

The value of the exports of thefe ftates before the revolution is not precifely afcertained; but the whole exportation of North America, including the remaining Britifh Colonies, and Newfoundland, (whofe fifhery alone was eftimated at more than 2,200,000 dollars in 1775) Bermuda, and the Bahamas, were computed to have been in 1771 15,280,000 dollars. In thefe were comprifed the fhipments between thofe iflands and the main, and from province to province, as every veffel which departed from one American port to another, was obliged to clear out her cargo as if deftined for a foreign country.

The amount of exports of the United States in the year 1799 was 33,142,187 dollars in domeftic produce, and 45,523,335 dollars in foreign produce, total 78,665,522 dollars. In time of peace however, fo great an amount cannot be expected.

In refpect to the commercial intercourfe between the United States and foreign nations, as regulated by exifting treaties, or by the laws of the land, the fubject is too extenfive, complex and important to be embraced to advantage within a compafs proportioned to the nature of this work.

It is afferted that the value of the manufactures of the United State is more than double the value of their exports in native commodities, and alfo much greater than the grofs value of all their imports, including the value of goods exported again. The American manufacturers confine their attention chiefly to articles of neceffity, comfort and utility. Since the eftablifhment of the prefent federal government the manufactures have increafed with great rapidity; and particularly thofe of the houfehold kind, which are carried on more or lefs in the families of almoft all the farmers and planters in the feveral ftates.

Standing armies are deemed inconfiftent with a republican government; we of courfe have none. Our military ftrength lies in a well difciplined militia. According to the cenfus of 1790, there were in the United States, 814,000 men of 16 years old and upwards, whites. Suppofe that the fuperannuated, the officers of government, and the other claffes of people who are excufed from military duty, amounted to 114,000, there remained at that period a militia of 700,000 men. The increafe of this number has been in proportion to the increafe of the whole number of inhabitants fince the year 1790. Of the militia a great proportion are well-difciplined, vetran troops. No nation or kingdom in Europe, can bring into the field an army of equal numbers, more formidable than can be raifed in the United States.

The Revenue of the United States is raifed from duties on the tonnage of veffels entered in the United States, and on imported goods, wares and merchandize, and from an excife on various articles of confumption. The amount of the duties arifing on the tonnage of veffels, for the year commencing October 1ft, 1790, and ending September 30th, 1791, amounted to 145,347 dollars. The duties arifing on goods, wares and merchandize, for the fame year amounted to 3,006,722 dollars. The amount of the revenue from the excife was then eftimated in round numbers at 400,000 dollars.

	Dols.	Cts.
Amount of the *Permanent* Revenue of the United States, 1795, arifing from duties on imports and tonnage, on diftilled fpirits, poftage of letters, patent fees, and intereft of bank ftock,	4,692,673	83
Temporary Revenue for the fame period,	1,859,626	91
Total,	6,552 300	74
The Expenditures for the fame year, for intereft of foreign and public debt, civil and naval departments, &c.	5,481,843	84
Excefs of Revenue beyond Expenditure,	1,070,456	90

At the clofe of the year 1794, the debt of the United States amounted to 64,825,538 dollars and 70 cents, exclufive of the public ftock purchafed by means of the finking fund, and fome other debts hereafter mentioned, which, if added, would have increafed it to about 74,000,000 dollars.

The act, making provifion for the debt of the United States, has appropriated the proceeds of the weftern lands as a fund for the difcharge of the public debt. And the act, making provifion for the reduction of the public debt, has appropriated all the furplus of the duties on imports and tonnage, to the end of the year 1790, to the purpofe of purchafing the debt at the market price; and has authorifed the Prefident to borrow the further fum of two millions of dollars for the fame object. Thefe meafures ferve to indicate the intention of the

United States.

the legiſlature, as early and as faſt as poſſible, to provide for the extinguiſhment of the exiſting debt.

"The foreign and domeſtic debts of the United States of America," ſays Mr. Coxe, (K) "as they appeared upon their public books on the firſt day of the current year, 1794, amounted to a little more than ſeventy-four millions of dollars. From this ſum, ſeven or eight millions are to be deducted, being different kinds of ſtock purchaſed in by means of the ſinking fund, or due upon the books or upon certificates from the United States to ſeveral of the members of the union: that is to themſelves. Of the entire balance, about fourteen millions will not bear intereſt until the year 1800. Much of the debt bears an intereſt at one half of the eſtabliſhed rate of this country. Some of it bears an intereſt of two-thirds, ſome of three-fourths, and ſome of four-fifths of the medium of the legal intereſt of the ſtates. It therefore reſults that forty-eight millions of dollars in ſpecie, about £.11,000,000 ſterling, would purchaſe or diſcharge all the debts of the United States, which they owe to individuals, or to bodies politic other than themſelves."

The preſent eligible ſituation of the United States, compared with that of Europe at large, as it reſpects taxes or contributions for the payment of all public charges, appears from the following ſtatement, furniſhed (1792) by a gentleman of acknowledged abilities. In the United States, the average proportion of his earnings which each citizen pays for the ſupport of the civil, military and naval eſtabliſhments, and for the diſcharge of the intereſt of the public debts of his country, is about *one dollar and a quarter;* equal to *two day's* labour, nearly; that is, 5 millions of dollars to 4 millions of people. In Great Britain, France, Holland, Spain, Portugal, Germany, &c. the taxes for theſe objects, on an average, amount to about *ſix dollars and a quarter*, to each perſon. Hence it appears that in the United States we enjoy the bleſſings of free government and mild laws; of perſonal liberty, and protection of property, for one-fifth part of the ſum for each individual, which is paid in Europe for the purchaſe of public benefits of a ſimilar nature, and too generally without attaining their objects: For leſs than *one-fifth*, indeed, as in European countries, in general, 10 days labour, on an average, do not amount to $6\frac{1}{4}$ dollars. In this eſtimate proper allowances are made for public debts. The Indian war in the United States, at preſent, requires nearly half a million of dollars, annually, extra; but this, being temporary only, is not taken into the eſtimate.

From the beſt data that can be collected, the taxes in the United States, for county, town and pariſh purpoſes; for the ſupport of ſchools, the poor, roads, &c. appear to be conſiderably leſs than in thoſe countries; and perhaps the objects of them, except in roads, is attained in a more perfect degree. Great preciſion is not to be expected in theſe calculations; but we have ſufficient documents to prove that we are not far from the truth. The proportion in the United States is well aſcertained; and with equal accuracy in France by Mr Neckar; and in England, Holland, Spain and other kingdoms in Europe, by him, Zimmerman, and other writers on the ſubject.

For the objects of the late war and civil government in the United States, nearly 12 millions of dollars were annually raiſed, for nine years ſucceſſively, apportioned on the number of inhabitants at that period, which amounted to a little ſhort of *four dollars* to each perſon. This was raiſed principally by direct taxes. Perhaps a contribution of *ſix dollars* a perſon would not have been ſo ſeverely felt, had a part of it been raiſed by impoſt and exciſe. Theſe ſums, raiſed for the war, by the free exertions of the people, obviate all ſuch objections as aſſert that the United States are poor; at the ſame time they evince that their ſituation is eligible and proſperous, by ſhewing how large a proportion of their earnings the people in general can apply to their private purpoſes.

A national mint was eſtabliſhed in 1791. It has ſince been provided by law that the purity and intrinſic value of the ſilver coin ſhall be equal to that of Spain; and of the gold coins, to thoſe of the ſtricteſt European nations. The government of the United States derives no profit from the coinage.

The Bank of the United States was incorporated by act of Congreſs, February 25th, 1791, by the name and ſtyle of *The Preſident, Directors and Company of the Bank of the United States.* The amount of the capital ſtock is 10 million dollars, one-fourth of which is in gold and ſilver; the other three-fourths, in that part of the public debt of the United States, which, at the time of payment, bears an accruing intereſt of 6 per cent. per annum. Two millions of this capital ſtock of 10 millions, was ſubſcribed by the Preſident, in behalf of the United States. The ſtockholders are to continue a corporate body, by the act, until the 4th day of March, 1811; and are capable, in law, of holding property to an amount not exceeding, in the whole, 15 million dollars, including the aforeſaid 10 million dollars, capital ſtock. The corporation may not at any time owe, whether by bond, bill or note, or other contract, more than 10 million dollars, over and above the monies then actually depoſited in the bank for ſafe keeping, unleſs the contracting of any greater debt ſhall have been previouſly authoriſed by a law of the United States. The corporation is not at liberty to receive more than 6 per cent. per annum for or upon its loans or diſcounts; nor to purchaſe any public debt whatever, or to deal or trade, directly or indirectly, in any thing except bills of exchange, gold or ſilver bullion, or in the ſale of goods really and truly pledged, for money lent, and not redeemed in due time, or of goods which ſhall be the produce of its bonds; they may ſell any part of the public debt of which its ſtock ſhall be compoſed. Loans not exceeding 100,000 dollars, may be made to the United States, and to particular ſtates, of a ſum not exceeding 50,000 dollars.

Offices for the purpoſes of diſcount and depoſit only, may be eſtabliſhed within the United States, upon the ſame terms, and in the ſame manner, as ſhall be practiſed at the bank. Five of theſe offices, called *Branch Banks*, have been already eſtabliſhed, viz. at Boſton, New-York, Baltimore, Charleſton, and Waſhington.

The

(K) View of the United States, p. 496.

The faith of the United States is pledged that no other bank ſhall be eſtabliſhed by any future law of the United States, during the continuance of the above corporation. The great benefits of this Bank, as it reſpects public credit and commerce, have already been experienced.

The conſtitution of the United States provides againſt the making of any law reſpecting an eſtabliſhment of religion, or prohibiting the free exerciſe of it. And in the conſtitutions of the reſpective ſtates, religious liberty is a fundamental principle. In this important article, our government is diſtinguiſhed from that of any of the nations in Europe. Religion here is placed on its proper baſis; without the feeble and unwarranted aid of the civil power, it is left, to be ſupported by its own evidence, by the lives of its profeſſors, and the Almighty care of its Divine Author. Its public teachers are maintained by an equal tax on property, by pew rents, monies at intereſt, marriage and burial fees, ſmall glebes, land rents, and voluntary contributions.

All being left at liberty to chooſe their own religion, the people, as might eaſily be ſuppoſed, have varied in their choice. The bulk of the people would denominate themſelves Chriſtians; a ſmall portion of them are Jews; ſome plead the ſufficiency of natural religion, and reject revelation as unneceſſary and fabulous; and many have yet their religion to chooſe. Chriſtians profeſs their religion under various forms, and with different ideas of its doctrines, ordinances and precepts. The following denominations of Chriſtians are more or leſs numerous in the United States, viz. Congregationaliſts, Preſbyterians, Dutch Reformed Church, Epiſcopalians, Baptiſts, Quakers or Friends, Methodiſts, Roman Catholics, German Lutherans, German Calviniſts or Preſbyterians, Moravians, Tunkers, Mennoniſts, Univerſaliſts and Shakers. For a particular account of theſe ſeveral ſects of Chriſtians, the reader is referred to Miſs H. Adams's "View of Religions."

Of theſe ſects of Chriſtians, Congregationaliſts are the moſt numerous. In New England alone, beſides thoſe which are ſcattered through the middle and ſouthern ſtates, there are about 1200 congregations of this denomination.

Next to Congregationaliſts, Preſbyterians are the moſt numerous denomination of Chriſtians in the United States. They have a conſtitution, by which they regulate all their eccleſiaſtical proceedings, and a confeſſion of faith, which all church officers and church members are required to ſubſcribe. Hence they have preſerved a ſingular uniformity in their religious ſentiments, and have conducted their eccleſiaſtical affairs with a great degree of order and harmony.

The body of the preſbyterians inhabit the middle and ſouthern ſtates, and are united under the ſame conſtitution. By this conſtitution, the Preſbyterians, who are governed by it, in 1796 were divided into four ſynods and eighteen preſbyteries; viz. 1. Synod of New York, 5 preſbyteries; 94 congregations; 61 ſettled miniſters.—2 Synod of Philadelphia, 6 preſbyteries; 92 congregations; 60 ſettled miniſters, beſides the miniſters and congregations belonging to Baltimore preſbytery.—3. Synod of Virginia, 4 preſbyteries; 70 congregations; 49 ſettled miniſters, excluſive of the congregations and miniſters of Tranſylvania preſbytery.—4. Synod of the Carolinas, 3 preſbyteries; 82 congregations; 42 ſettled miniſters; the miniſters and congregations in Abbington preſbytery not included. If we ſuppoſe the number of congregations in the preſbyteries which made no returns to their Synods to be 100, and the number of ſettled miniſters in the ſame to be 40, the whole number of preſbyterian congregations in this connexion, will be 438, which are ſupplied by 223 ſettled miniſters, and between 70 and 80 candidates, beſides a number of ordained miniſters who have no particular charges. Each of the four Synods meet annually; beſides which they have a joint meeting by their commiſſioners, once a year, in General Aſſembly at Philadelphia.

The Preſbyterian churches are governed by congregational, preſbyterial and ſynodical aſſemblies. Theſe aſſemblies poſſeſs no civil juriſdiction. Their power is wholly moral or ſpiritual, and that only miniſterial and declarative. They poſſeſs the right of requiring obedience to the laws of Chriſt, and of excluding the diſobedient from the privileges of the church; and the powers requiſite for obtaining evidence and inflicting cenſure; but the higheſt puniſhment to which their authority extends, is to exclude the contumacious and impenitent from the congregation of believers.

The Dutch Reformed churches in the United States, who maintain the doctrine of the ſynod of Dort, held in 1618, are between 70 and 80 in number, conſtituting ſix claſſes, which form one ſynod, ſtyled "The Dutch Reformed Synod of New York and New Jerſey." The claſſes conſiſt of miniſters and ruling elders; each claſſis delegates two miniſters and an elder to repreſent them in ſynod.

The number of Proteſtant Epiſcopal churches in the United States is not aſcertained; in New England there are between forty and fifty; but in the ſouthern ſtates they are much more numerous. Biſhops of Connecticut, New York, Pennſylvania, Virginia, Maſſachuſetts, Vermont, Maryland and South Carolina have been elected by the conventions of their reſpective ſtates, and have been duly conſecrated.

The Baptiſts, with ſome exceptions, are upon the Calviniſtic plan as to doctrines, and independents as to church government and diſcipline.

Of this denomination there were in 1793—45 Aſſociates, 1032 Churches, 1291 Miniſters, and 73471 Members.

Friends, commonly called Quakers.(L) This denomination of Chriſtians aroſe about the year 1648, and were firſt collected into religious ſocieties by their highly

 reſpected

(L) They received their appellation from this circumſtance—In the year 1650, George Fox, being brought before two juſtices in Derbyſhire, one of them, ſcoffing at him, for having bidden him and thoſe about him, to *tremble* at the word of the Lord, gave to him and his followers, the name of *Quakers*; a name by which they have ſince been uſually denominated; but they themſelves adopted the appellation of *Friends*.

United States.

respected elder, George Fox. They came to America as early as 1656. The first settlers of Pennsylvania were all of this denomination; and the number of Friends meetings in the United States at present, is between 300 and 400, 250 of which are south of the state of New York.

The Methodist denomination of Christians arose in England in 1739; and made their first appearance in America, about the year 1772. Their general style is, "The United Societies of the Methodist Episcopal Church."

The late celebrated Mr John Wesley, is considered as the father of the class of Methodists, called *Arminian Methodists*. The famous Mr Whitefield, was the leader of the *Calvinistic Methodists*, who are numerous in England, and a few are in different parts of the United States.

In 1797, the number of *Wesleian* Methodists in the United States, was 46,445 whites, 12,218 blacks; of these 2482 were in New England, 8 only of which were blacks.

The whole number of Roman Catholics in the United States was estimated, in 1796, at about 50,000; one half of which were in the state of Maryland. They have a Bishop, who resides in Maryland, and many of their congregations are large and respectable.

The German inhabitants in these states, who principally belong to Pennsylvania and New York, are divided into a variety of sects; the principal of which are Lutherans, Calvinists or Presbyterians, Moravians, Tunkers, and Mennonists. Of these, the German Lutherans are the most numerous. Of this denomination, and the German Presbyterians or Calvinists, who are next to them in numbers, there are upwards of 60 ministers, in Pennsylvania—and the former have 12, and the latter 6 churches in the state of New York. Many of their churches are large and splendid, and in some instances furnished with organs. These two denominations live together in the greatest harmony, often preaching in each others churches, and sometimes uniting in the erection of a church, in which they alternately worship.

The Moravians are a respectable body of Christians in these states. Of this denomination, there were, in 1788, about 1300 souls in Pennsylvania; viz. at Bethlehem, between 5 and 600, which number has since increased—at Nazareth, 450; at Litiz, upwards of 300. Their other settlements in the United States, are at Hope, in New Jersey, about 100 souls; at Wachovia, on Yadkin river, North Carolina, containing 6 churches. Besides these regular settlements, formed by such only as are members of the Brethren's Church, and live together in good order and harmony, there are in different parts of Pennsylvania, Maryland and New Jersey, and in the cities and towns of Newport, (Rhode Island), New York, Philadelphia, Lancaster, Yorktown, &c. congregations of the brethren, who have their own church and minister, and hold the same principles, doctrinal tenets, and church rites and ceremonies as the former, though their local situation does not admit of such particular regulations as are peculiar to the regular settlements.

They call themselves, "The *United Brethren of the Protestant Episcopal Church*." They are called Moravians, because the first settlers in the English dominions were chiefly migrants from Moravia. These were the remnant and genuine descendants of the church of the ancient United Brethren, established in Bohemia and Moravia, as early as the year 1456. About the middle of the 16th century, they left their native country to avoid persecution, and to enjoy liberty of conscience, and the true exercise of the religion of their forefathers. They were received in Saxony, and other Protestant dominions, and were encouraged to settle among them, and were joined by many serious people of other denominations. They adhere to the Augustan Confession of Faith, which was drawn up by the Protestant divines at the time of the reformation in Germany, in the year 1530, and presented at the diet of the empire at Augsburg; and which, at that time, contained the doctrinal system of all the established Protestant churches. They retain the discipline of their ancient church, and make use of Episcopal ordination, which has been handed down to them in a direct line of succession for more than three hundred years (M).

They profess to live in strict obedience to the ordinances of Christ, such as the observation of the Sabbath, Infant Baptism, and the Lord's Supper; and in addition to these, they practise the foot washing, the kiss of love, and the use of the lot.

They were introduced into America by Count Zinzendorf, and settled at Bethlehem, which is their principal settlement in America, as early as 1741. Regularity, industry, ingenuity and economy, are characteristics of these people.

The Tunkers, so called in derision from the word *tunken, to put a morsel in sauce*, first appeared in America, in the fall of the year 1719, when about twenty families landed in Philadelphia, and dispersed themselves in various parts of Pennsylvania. They are what are called General Baptists, and hold to general redemption and general salvation.

Their principal settlement was at Ephrata, sometimes called Tunkers-town, in Lancaster county, sixty miles westward of Philadelphia. Besides this congregation there were, in 1770, fourteen others in various other parts of Pennsylvania, and some in Maryland. The whole, exclusive of those in Maryland, amounted to upwards of 2000 souls.

The Mennonists derive their name from Menno Simon, a native of Witmars, in Germany, a man of learning, born in the year 1505, in the time of the reformation by Luther and Calvin. He was a famous Roman Catholic preacher, till about the year 1531, when he became

(M) See David Crantz's History of "The Ancient and Modern United Brethren's Church, translated from the German, by the Rev Benjamin La Trobe." London, 1780. Those who wish to obtain a thorough and impartial knowledge of their religious sentiments and customs, may see them excellently summed up in a plain but nervous style, in "An Exposition of Christian Doctrine, as taught in the Protestant Church of the United Brethren," written in German, by A. G. Spangenberg; and translated and published in English in 1794.

ed es.

came a Baptiſt. Some of his followers came into Pennſylvania from New York and ſettled at Germantown, as early as 1692. This is at preſent their principal congregation, and the mother of the reſt. Their whole number, in 1770, in Pennſylvania, was upwards of 4000, divided into thirteen churches, and forty-two congregations, under the care of fifteen ordained miniſters, and fifty-three licenſed preachers.

The denomination ſtyled Univerſaliſts, has of late years conſiderably increaſed in the United States, they have a number of churches in different places; though the tenets of the different ſocieties vary conſiderably, they all agree in the belief of General Salvation.

There is a ſmall ſect of Chriſtians called Shakers, which have exiſted in America ſince 1774, when a few of them came from England to New York, and there being joined by a few others, they ſettled at Niſqueunia, above Albany, which is their principal ſettlement: A few others are ſcattered in different parts of the country but are now diminiſhing.

The Jews are not numerous in the United States. They have ſynagogues at Savanna, Charleſton, (S. C.) Philadelphia, New York, and Newport. Beſides thoſe who reſide at theſe places, there are a few others ſcattered in different towns in the United States.

The Jews in Charleſton, among other peculiarities in burying their dead, have theſe: After the funeral dirge is ſung, and juſt before the corpſe is depoſited in the grave, the coffin is opened, and a ſmall bag of earth, taken from the grave, is carefully put under the head of the deceaſed; then ſome powder, ſaid to be earth brought from Jeruſalem, and carefully kept for this purpoſe, is taken and put upon the eyes of the corpſe, in token of their remembrance of the Holy Land, and of their expectations of returning thither in God's appointed time. Whether this cuſtom is univerſal among the Jews, is not known.

They generally expect a glorious return to the Holy Land, when they ſhall be exalted above all the nations of the earth. And they flatter themſelves that the period of their return will ſpeedily arrive, though they do not venture to fix the preciſe time.

The whole number of perſons who profeſs the Jewiſh religion, in all parts of the world, is ſuppoſed to be about three millions; who as their phraſe is, are witneſſes of the unity of *God* in all the nations in the world.

After the revolution (of which an account has been given in Encyclopædia volume 1ſt) the United States began to experience the defects of their general government. While an enemy was in the country, fear, which had firſt impelled the colonies to aſſociate in mutual defence, continued to operate as a band of political union. It gave to the reſolutions and recommendations of Congreſs the force of laws, and generally commanded a ready acquieſcence on the part of the ſtate legiſlatures. Articles of confederation and perpetual union had been framed in Congreſs, and ſubmitted to the conſideration of the ſtates, in the year 1778. Some of the ſtates immediately acceded to them; but others, which had not unappropriated lands, heſitated to ſubſcribe a compact which would give an advantage to the ſtates which poſſeſſed large tracts of unlocated lands, and were thus capable of a great ſuperiority in wealth and population. All objections, however, had been overcome, and by the acceſſion of Maryland, in March, 1781, the articles of confederation were ratified, as the frame of government for the United States.

United States.

Theſe articles, however, were framed during the rage of war, when a principle of common ſafety ſupplied the place of a coercive power in government; by men who could have had no experience in the art of governing an extenſive country, and under circumſtances the moſt critical and embarraſſing. To have offered to the people, at that time, a ſyſtem of government armed with the powers neceſſary to regulate and control the contending intereſts of thirteen States, and the poſſeſſions of millions of people, might have raiſed a jealouſy between the ſtates or in the minds of the people at large, that would have weakened the operations of war, and perhaps have rendered a union impracticable. Hence the numerous defects of the confederation.

On the concluſion of peace, theſe defects began to be felt. Each ſtate aſſumed the right of diſputing the propriety of the reſolutions of Congreſs, and the intereſt of an individual ſtate was placed in oppoſition to the common intereſt of the union. In addition to this ſource of diviſion, a jealouſy of the powers of Congreſs began to be excited in the minds of the people.

The jealouſy of the privileges of freemen had been rouſed by the oppreſſive act of the Britiſh parliament; and no ſooner had the danger from this quarter ceaſed, than the fears of the people changed their object, and were turned againſt their own rulers.

In this ſituation, there were not wanting men of induſtry and talents, who have been enemies to the revolution, and who embraced the opportunity to multiply the apprehenſions of people and increaſe the popular diſcontents. A remarkable inſtance of this happened in Connecticut. As ſoon as the tumults of war had ſubſided, an attempt was made to convince the people, that the act of Congreſs paſſed in 1778, granting to the officers of the army half pay for life, was highly unjuſt and tyrannical; and that it was but the firſt ſtep towards the eſtabliſhment of penſions and an uncontrollable deſpotiſm. The act of Congreſs, paſſed in 1783, commuting half pay for life, for five years full pay, was deſigned to appeaſe the apprehenſions of the people, and to convince them that this gratuity was intended merely to indemnify the officers for their loſſes by the depreciation of the paper currency, and not to eſtabliſh a precedent for the granting of penſions. This act however did not ſatisfy the people, who ſuppoſed that the officers had been generally indemnified for the loſs of their pay, by the grants made them from time to time by the legiſlatures of the ſeveral ſtates. Beſides, the act, while it gave five years full pay to the officers, allowed but one year's pay to the privates; a diſtinction which had great influence in exciting and continuing the popular ferment, and one that turned a large ſhare of the public rage againſt themſelves.

The moment an alarm was raiſed reſpecting this act of Congreſs, the enemies of our independence became active in blowing up the flame, by ſpreading reports unfavourable to the general government, and tending to create public diſſentions. Newſpapers, in ſome parts of the country, were filled with inflammatory publications; while falſe reports and groundleſs inſinuations were induſtriouſly circulated to the prejudice of Congreſs and the officers of the late army. Among a people feelingly alive to every thing that could affect the rights for which

which they had been contending, these reports could not fail of having a powerful effect; the clamour soon became general; the officers of the army, it was believed, had attempted to raise their fortunes on the distresses of their fellow-citizens, and Congress become the tyrants of their country.

Connecticut was the seat of this uneasiness; although other states were much agitated on the occasion. But the inhabitants of that state, accustomed to order and a due subordination to the laws, did not proceed to outrages; they took their usual mode of collecting the sense of the state—assembled in town meetings—appointed committees to meet in convention, and consult what measures should be adopted to procure a redress of their grievances. In this convention, which was held at Middletown, some nugatory resolves were passed, expressing the disapprobation of the half-pay act, and the subsequent commutation of the grant for five years whole pay. The same spirit also discovered itself in the assembly at their October session, 1783. A remonstrance against the acts in favour of the officers, was framed in the house of representatives, and notwithstanding the upper house refused to concur in the measure, it was sent to Congress, as already mentioned.

During this situation of affairs, the public odium against the officers was augmented by another circumstance. The officers, just before the disbanding of the army, had formed a society, called by the name of the *Cincinnati*, after the Roman Dictator, Cincinnatus.

Whatever were the real views of the framers of this institution, its design was generally understood to be harmless and honourable. The ostensible views of the society could not however screen it from popular jealousy. A spirited pamphlet appeared in South Carolina, the avowed production of Mr Burke, one of the Judges of the supreme court in that state, in which the author attempted to prove that the principles on which the society was formed, would, in process of time, originate and establish an order of nobility in this country, which would be repugnant to the genius of our republican governments, and dangerous to liberty. This pamphlet appeared in Connecticut, during the commotions raised by the half-pay and commutation acts and contributed not a little to spread the flame of opposition.

Notwithstanding the discontents of the people were general, and ready to burst forth into sedition, yet men of information, viz. the officers of government, the clergy, and persons of liberal education, were mostly opposed to the unconstitutional steps taken by the committees and convention at Middletown. They supported the propriety of the measures of Congress, both by conversation and writing, proved that such grants to the army were necessary to keep the troops together, and that the expense would not be enormous nor oppressive. During the close of the year 1783, every possible exertion was made to enlighten the people, and such was the effect of the arguments used by the minority, that in the beginning of the following year the opposition subsided, the committees were dismissed, and tranquillity restored to the state. In May, the legislature were able to carry several measures which had before been extremely unpopular. An act was passed granting the impost of five per cent. to Congress; another giving great encouragement to commerce; and several towns were incorporated with extensive privileges, for the purpose of regulating the exports of the state, and facilitating the collection of debts.

The opposition to the congressional acts in favour of the officers, and to the order of the Cincinnati, did not rise to the same pitch in the other states as in Connecticut; yet it produced much disturbance in Massachusetts, and some others. Jealousy of power had been universally spread among the people of the United States. The destruction of the old forms of governments, and the licentiousness of war, had, in a great measure, broken their habits of obedience; their passions had been inflamed by the cry of despotism; and like centinels, who have been suddenly surprised by the approach of an enemy, the rustling of a leaf was sufficient to give them an alarm. This spirit of jealousy operated with other causes to relax the energy of federal operations.

During the war, vast sums of paper currency had been emitted by Congress, and large quantities of specie had been introduced, towards the close of the war, by the French army, and the Spanish trade. This plenty of money enabled the states to comply with the first requisitions of Congress; so that during two or three years, the federal treasury was, in some measure, supplied. But when the danger of war had ceased, and the vast importations of foreign goods had lessened the quantity of circulating specie, the states began to be very remiss in furnishing their proportion of monies. The annihilation of the credit of the paper bills had totally stopped their circulation, and the specie was leaving the country in cargoes, for remittances to Great Britain; still the luxurious habits of the people, contracted during the war, called for new supplies of goods; and private gratifications seconded the narrow policy of state interest in defeating the operations of the general government.

Thus the revenues of Congress were annually diminishing; some of the states wholly neglecting to make provision for paying the interest of the national debt; others making but a partial provision, until the scanty supplies received from a few of the richest states, would hardly satisfy the demands of the civil list.

This weakness of the federal government, in conjunction with the flood of certificates or public securities, which Congress could neither fund nor pay, occasioned them to depreciate to a very inconsiderable value. The officers and soldiers of the late army, and those who furnished supplies for public exigencies, were obliged to receive for wages these certificates, or promissory notes, which passed at a fifth, an eighth or tenth of their nominal value; being thus deprived at once of the greatest part of the reward due for their services. Some indeed profited by speculations in these evidences of the public debt; but such as were under a necessity of parting with them, were robbed of that support which they had a right to expect and demand from their countrymen.

Pennsylvania indeed made provision for paying the interest of her debts, both state and federal; assuming her supposed proportion of the continental debt, and giving the creditors her own state notes in exchange for those of the United States. The resources of that state are immense, but she was not able to make punctual payments, even in a depreciated paper currency.

Massachusetts, in her zeal to comply fully with the requisitions of Congress, and satisfy the demands of her own

own creditors, laid a heavy tax upon the people. This was the immediate caufe of the rebellion in that ftate, in 1786. But a heavy debt lying on the ftate, added to burdens of the fame nature, upon almoft every corporation within it; a decline, or rather an extinction of public credit; a relaxation and corruption of manners, and a free ufe of foreign luxuries; a decay of trade and manufactures, with a prevailing fcarcity of money; and, above all, individuals involved in debt to each other;—thefe were the real, though more remote caufes of the infurrection. It was the tax which the people were required to pay, that caufed them to feel the evils which we have enumerated: This called forth all their other grievances; and the firft act of violence committed, was the burning or deftroying of the tax-bill. This fedition threw the ftate into a convulfion which lafted about a year; courts of juftice were violently obftructed; the collection of debts was fufpended; and a body of armed troops under the command of general Lincoln, was employed, during the winter of 1786, to difperfe the infurgents. Yet fo numerous were the latter in the counties of Worcefter, Hampfhire and Berkfhire, and fo obftinately combined to oppofe the execution of law by force, that the governor and council of the ftate thought proper not to entruft general Lincoln with military powers, except to act on the defenfive, and to repel force with force, in cafe the infurgents fhould attack him. The leaders of the rebels, however, were not men of talents; they were defperate, but without fortitude; and while they were fupported with a fuperior force, they appeared to be impreffed with that confcioufnefs of guilt, which awes the moft daring wretch, and makes him fhrink from his purpofe. This appears by the conduct of a large party of the rebels before the magazine at Springfield; where general Shepard, with a fmall guard was ftationed to protect the continental ftores. The infurgents appeared upon the plain, with a vaft fuperiority of numbers, but a few fhot from the artillery made the multitude retreat in diforder, with the lofs of four men. This fpirited conduct of general Shepard, with the induftry, perfeverance and prudent firmnefs of general Lincoln, difperfed the rebels—drove the leaders from the ftate, and reftored tranquillity. An act of indemnity was paffed in the legiflature for all the infurgents, except a few of the leaders, on condition they fhould become peaceable fubjects, and take the oath of allegiance. The leaders afterwards petitioned for pardon, which, from motives of policy, was granted by the legiflature (N).

But the lofs of public credit, popular difturbances and infurrections, were not the only evils which were generated by the peculiar circumftances of the times. The emiffions of bills of credit and tender laws, were added to the black catalogue of political diforders.

The expedient of fupplying the deficiencies of fpecie, by emiffions of paper bills, was adopted very early in the colonies. The expedient was obvious, and produced good effects. In a new country, where population is rapid, and the value of lands increafing, the farmer finds an advantage in paying legal intereft for money; for if he can pay the intereft by his profits, the increafing value of his lands will in a few years difcharge the principal.

In no colony was this advantage more fenfibly experienced than in Pennfylvania. The emigrations to that province were numerous; the natural population rapid; and thefe circumftances combined, advanced the value of real property to an aftonifhing degree. As the firft fettlers there, as well as in other provinces, were poor, the purchafe of a few foreign articles drained them of fpecie. Indeed for many years the balance of trade muft have neceffarily been greatly againft the colonies.

But bills of credit, emitted by the ftate and loaned to the induftrious inhabitants, fupplied the want of fpecie, and enabled the farmer to purchafe ftock. Thefe bills were generally a legal tender in all colonial or private contracts, and the fums iffued did not generally exceed the quantity requifite for a medium of trade; they retained their full nominal value in the purchafe of commodities. But as they were not received by the Britifh merchants, in payment of their goods, there was a great demand for fpecie and bills, which occafioned the latter at various times to appreciate. Thus was introduced a difference between the Englifh fterling money and the currencies of the colonies, which remains to this day (O).

The advantages the colonies had derived from bills of credit, under the Britifh government, fuggefted to Congrefs, in 1775, the idea of iffuing bills for the purpofe of carrying on the war. And this was perhaps their only expedient. Money could not be raifed by taxation; it could not be borrowed. The firft emiffions had no other effect upon the medium of commerce, than to drive the fpecie from circulation. But when the paper fubftituted for fpecie, had, by repeated emiffions, augmented the fum in circulation much beyond the ufual fum of fpecie, the bills began to lofe their value. The depreciation continued in proportion to the fums emitted, until feventy, and even one hundred and fifty nominal paper dollars, were hardly an equivalent for one Spanifh milled dollar. Still, from the year 1775 to 1781, this depreciating paper currency was almoft the only medium of trade. It fupplied the place of fpecie, and enabled Congrefs to fupport a numerous army; until the fum in circulation amounted to two hundred millions of dollars. But about the year 1780, fpecie began to be plentiful, being introduced by the French army, a private trade with the Spanifh iflands, and an illicit intercourfe with the Britifh garrifon at New York. This circumftance accelerated the depreciation of paper bills, until their value had funk almoft to nothing. In 1781, the merchants and brokers in the fouthern ftates, apprehenfive of the approaching fate of the

(N) See a well written impartial Hiftory of this rebellion, by the late George Richards Minot, Efq.

(O) A Dollar in fterling money, is 4/6. But the price of a dollar rofe in New England currency to 6f. in New York to 8f. in New Jerfey, Pennfylvania and Maryland to 7/6. in Virginia to 6f. in North Carolina to 8f. in South Carolina and Georgia to 4/8. This difference, originating between paper and fpecie, or bills, continued afterwards to exift in the nominal eftimation of gold and filver.

United States.

the currency, pushed immense quantities of it suddenly into New England, made vast purchases of goods in Boston; and instantly the bills vanished from circulation.

The whole history of this continental paper is a history of public and private frauds. Old specie debts were often paid in a depreciated currency; and even new contracts for a few weeks or days were often discharged with a small part of the value received. From this plenty and fluctuating state of the medium, sprung hosts of speculators and itinerant traders, who left their honest occupations for the prospect of immense gains, in a fraudulent business, that depended on no fixed principles, and the profits of which could be reduced to no certain calculations.

To increase these evils, a project was formed to fix the price of articles, and restrain persons from giving or receiving more for any commodity than the price stated by authority. These regulating acts were reprobated by every man acquainted with commerce and finance; as they were intended to prevent an effect without removing the cause. To attempt to fix the value of money, while streams of bills were incessantly flowing from the treasury of the United States, was as ridiculous as an attempt to restrain the rising of water in rivers amidst showers of rain.

Notwithstanding all opposition, some states framed and attempted to enforce these regulating acts. The effect was, a momentary apparent stand in the price of articles; innumerable acts of collusion and evasion among the dishonest; numberless injuries done to the honest; and finally a total disregard of all such regulations, and the consequent contempt of laws and the authority of the magistrate.

During these fluctuations of business, occasioned by the variable value of money, people lost sight, in some measure, of the steady principles which had before governed their intercourse with each other. Speculation followed and relaxed the rigour of commercial obligations.

Industry likewise had suffered by the flood of money which had deluged the states. The prices of produce had risen in proportion to the quantity of money in circulation, and the demand for the commodities of the country. This made the acquisition of money easy, and indolence and luxury, with their train of desolating consequences, spread themselves among all descriptions of people.

But as soon as hostilities between Great Britain and America were suspended, the scene was changed. The bills emitted by Congress had for some time before ceased to circulate: and the specie of the country was soon drained off to pay for foreign goods, the importations of which exceeded all calculation. Within two years from the close of the war, *a scarcity of money* was the general cry. The merchants found it impossible to collect their debts, and make punctual remittances to their creditors in Great Britain; and the consumers were driven to the necessity of retrenching their superfluities in living, and of returning to their ancient habits of industry and economy.

This change was however progressive and slow. In many of the states which suffered by the numerous debts they had contracted, and by the distresses of war, the people called aloud for emissions of paper bills to supply the deficiency of a medium. The depreciation of the continental bills was a recent example of the ill effects of such an expedient, and the impossibility of supporting the credit of paper, was urged by the opposers of the measure as a substantial argument against adopting it. But nothing would silence the popular clamour; and many men, of the first talents and eminence, united their voices with that of the populace. Paper money had formerly maintained its credit, and been of singular utility; and past experience, notwithstanding a change of circumstances, was an argument in its favour that bore down all opposition.

Pennsylvania, although one of the richest states in the union, was the first to emit bills of credit, as a substitute for specie. But the revolution had removed the necessity of it, at the same time, that it had destroyed the means by which its former credit had been supported. Lands, at the close of the war, were not rising in value; bills on London could not so readily be purchased, as while the province was dependent on Great Britain; the state was split into parties, one of which attempted to defeat the measures most popular with the other; and the depreciation of continental bills, with the injuries which it had done to individuals, inspired a general distrust of all public promises.

Notwithstanding a part of the money was loaned on good landed security, and the faith of that wealthy state pledged for the redemption of the whole at its nominal value, yet the advantages of specie as a medium of commerce, especially as an article of remittance to London, soon made a difference of ten per cent. between the bills of credit and specie. This difference may be considered rather as an appreciation of gold and silver, than a depreciation of paper; but its effects, in a commercial state, must be highly prejudicial. It opens the door to frauds of all kinds, and frauds are usually practised on the honest and unsuspecting, especially upon all classes of labourers.

North Carolina, South Carolina, and Georgia, had recourse to the same wretched expedient to supply themselves with money; not reflecting that industry, frugality, and good commercial laws are the only means of turning the balance of trade in favour of a country, and that this balance is the only permanent source of solid wealth and ready money. But the bills they emitted shared a worse fate than those of Pennsylvania; they expelled almost all the circulating cash from the States; they lost a great part of their nominal value, they impoverished the merchants, and embarrassed the planters.

The state of Virginia tolerated a base practice among the inhabitants of cutting dollars and smaller pieces of silver, in order to prevent it from leaving the state. This pernicious practice prevailed also in Georgia. (P)

Maryland escaped the calamity of a paper currency. The house of delegates brought forward a bill for the emission of bills of credit to a large amount; but the senate

(P) A dollar was usually cut in five pieces, and each passed by toll for a quarter; so the man who cut it gained a quarter, or rather a fifth.

senate firmly and succesfsfully resisted the pernicious scheme. The opposition between the two houses was violent and tumultuous; it threatened the state with anarchy; but the question was carried to the people, and the good sense of the senate finally prevailed.

New Jersey, situated between two of the largest commercial towns in America, was consequently drained of specie. This state also emitted a large sum in bills of credit, which served to pay the interest of the public debt; but the currency depreciated, as in other states.

Rhode Island exhibited a melancholy proof of that licentiousness and anarchy which always follows a relaxation of the moral principles. In a rage for supplying the state with money, and filling every man's pocket without obliging him to earn it by his diligence, the legislature passed an act for making one hundred thousand pounds in bills; a sum much more than sufficient for a medium of trade in that state, even without any specie. The merchants in Newport and Providence, opposed the act with firmness; and their opposition added fresh vigour to the resolution of the assembly, and induced them to enforce the scheme by a legal tender of a most extraordinary nature. They passed an act, ordaining that if any creditor should refuse to take their bills, for any debt whatever, the debtor might lodge the sum due, with a justice of the peace, who should give notice of it in the public papers; and if the creditor did not appear and receive the money within six months from the first notice, his debt should be forfeited. This act astonished all honest men; and even the promoters of paper money-making in other states, and other principles, reprobated this act of Rhode Island, as wicked and oppressive. But the state was governed by faction. During the cry for paper money, a number of boisterous, ignorant men, were elected into the legislature, from the smaller towns in the state. Finding themselves united with a majority in opinion, they formed and executed any plan their inclination suggested; they opposed every measure that was agreeable to the mercantile interest; they not only made bad laws to suit their own wicked purposes, but appointed their own corrupt creatures to fill the judicial and executive departments. Their money depreciated sufficiently to answer all their vile purposes in the discharge of debts; business almost totally ceased; all confidence was lost; the state was thrown into confusion at home, and was execrated abroad.

Massachusetts Bay had the good fortune, amidst her political calamities, to prevent an emission of bills of credit. New Hampshire made no paper; but in the distresses which followed her loss of business after the war, the legislature made horses, lumber and most articles of produce, a legal tender in the fulfilment of contracts. It is doubtless unjust to oblige a creditor to receive any thing for his debt, which he had not in contemplation at the time of the contract. But as the commodities which were to be a tender by law, in New Hampshire, were of an intrinsic value, bearing some proportion to the amount of the debt, the injustice of the law was less flagrant, than that which enforced the tender of paper in Rhode Island. Indeed a similar law prevailed for some time in Massachusetts; and in Connecticut it is optional with the creditor either to imprison the debtor, or take land on execution, at a price to be fixed by three indifferent freeholders; provided no other means of payment shall appear to satisfy the demand. It must not however be omitted, that while the most flourishing commercial states introduced a paper medium, to the great injury of honest men, a bill for an emission of paper in Connecticut, where there is very little specie, could never command more than one-eighth of the votes of the legislature. The movers of the bill have hardly escaped ridicule: so generally is the measure reprobated, as a source of frauds and public mischief.

United States.

The legislature of New York, a state that had the least necessity and apology for making paper money, as her commercial advantages always furnish her with specie sufficient for a medium, issued a large sum in bills of credit, which supported their value better than the currency of any other state. Still the paper raised the value of specie, which is always in demand for exportation, and this difference of exchange between paper and specie, ever exposes commerce to most of the inconveniencies resulting from a depreciated medium.

Such is the history of paper money thus far; a miserable substitute for real coin, in a country where the reins of government are too weak to compel the fulfilment of public engagements, and where all confidence in public faith is totally destroyed.

While the states were thus endeavouring to repair the loss of specie, by empty promises, and to support their business by shadows, rather than by reality, the British ministry formed some commercial regulations that deprived them of the profits of their trade to the West Indies and Great Britain. Heavy duties were laid upon such articles as were remitted to the London merchants for their goods, and such were the duties upon American bottoms, that the states were almost wholly deprived of the carrying trade. A prohibition was laid upon the produce of the United States, shipped to the English West India Islands in American built vessels, and in those manned by American seamen. These restrictions fell heavy upon the eastern states, which depended much upon ship-building for the support of their trade; and they materially injured the business of the other states.

Without a union that was able to form and execute a general system of commercial regulations, some of the states attempted to impose restraints upon the British trade that should indemnify the merchant for the losses he had suffered, or induce the British ministry to enter into a commercial treaty and relax the rigor of their navigation laws.

These measures, however, produced nothing but mischief. The states did not act in concert, and the restraints laid on the trade of one state, operated to throw the business into the hands of its neighbour. Massachusetts, in her zeal to counteract the effect of the English navigation laws, laid enormous duties upon British goods imported into that state; but the other states did not adopt a similar measure; and the loss of business soon obliged that state to repeal or suspend the law. Thus when Pennsylvania laid heavy duties on British goods, Delaware and New Jersey made a number of free ports to encourage the landing of goods within the limits of those states; and the duties in Pennsylvania served no purpose, but to create smuggling.

Thus divided, the states began to feel their weakness. Most of the legislatures had neglected to comply with the requisitions of Congress for furnishing the federal treasury;

treaſury; the reſolves of Congreſs were diſregarded; the propoſition for a general impoſt to be laid and collected by Congreſs was negatived firſt by Rhode Iſland, and afterwards by New York. The Britiſh troops continued, under pretence of a breach of treaty on the part of America, to hold poſſeſſion of the forts on the frontiers of the ſtates. Many of the ſtates individually were infeſted with popular commotions or iniquitous tender laws, while they were oppreſſed with public debts; the certificates or public notes had loſt moſt of their value, and circulated merely as the objects of ſpeculation; Congreſs loſt their reſpectability, and the United States their credit and importance.

In the midſt of theſe calamities, a propoſition was made in 1785, in the houſe of delegates in Virginia, to appoint commiſſioners, to meet ſuch as might be appointed in the other ſtates, who ſhould form a ſyſtem of commercial regulations for the United States, and recommend it to the ſeveral legiſlatures for adoption. Commiſſioners were accordingly appointed, and a requeſt was made to the legiſlature of the other ſtates to accede to the propoſition. Accordingly ſeveral of the ſtates appointed commiſſioners, who met at Annapolis in the ſummer of 1786, to conſult what meaſures ſhould be taken to unite the ſtates in ſome general and efficient commercial ſyſtem. But as the ſtates were not all repreſented, and the powers of the commiſſioners were, in their opinion, too limited to propoſe a ſyſtem of regulations adequate to the purpoſes of government, they agreed to recommend a general convention to be held at Philadelphia the next year, with powers to frame a general plan of government for the United States. This meaſure appeared to the commiſſioners abſolutely neceſſary. The old confederation was eſſentially defective. It was deſtitute of almoſt every principle neceſſary to give effect to legiſlation.

It was defective in the article of legiſlating over ſtates, inſtead of individuals. All hiſtory teſtifies that recommendations will not operate as laws, and compulſion cannot be exerciſed over ſtates, without violence, war and anarchy. The confederation was alſo deſtitute of a ſanction to its laws. When reſolutions were paſſed in Congreſs, there was no power to compel obedience by fine, by ſuſpenſion of privileges, or other means. It was alſo deſtitute of a guarantee for the ſtate governments. Had one ſtate been invaded by its neighbour, the union was not conſtitutionally bound to aſſiſt in repelling the invaſion, and ſupporting the conſtitution of the invaded ſtate. The confederation was further deficient in the principle of apportioning the quotas of money to be furniſhed by each ſtate; in a want of power to form commercial laws, and to raiſe troops for the defence and ſecurity of the union; in the equal ſuffrage of the ſtates, which placed Rhode Iſland on a footing in Congreſs with Virginia; and to crown all the defects, we may add the want of a judiciary power, to define the laws of the union, and to reconcile the contradictory deciſions of a number of independent judicatories.

Theſe and many inferior defects were obvious to the commiſſioners, and therefore they urged a general convention, with powers to form and offer to the confideration of the ſtates, a ſyſtem of general government that ſhould be leſs exceptionable. Accordingly in May, 1787, delegates from all the ſtates, except Rhode Iſland, aſſembled at Philadelphia, and choſe General Waſhington for their preſident. After four months deliberation, in which the claſhing intereſts of the ſeveral ſtates appeared in all their force, the convention agreed to recommend the plan of federal government which we have already recited.

As ſoon as the plan of the federal conſtitution was ſubmitted to the legiſlatures of the ſeveral ſtates, they proceeded to take meaſures for collecting the ſenſe of the people upon the propriety of adopting it. In the ſmall ſtate of Delaware, a convention was called in November, which, after a few days deliberation, ratified the conſtitution without a diſſenting voice.

In the convention of Pennſylvania, held the ſame month, there was a ſpirited oppoſition to the new form of government. The debates were long and intereſting. Great abilities and firmneſs were diſplayed on both ſides; but on the 13th of December, the conſtitution was received by two-thirds of the members. The minority were diſſatisfied, and with an obſtinacy that ill became the repreſentatives of a free people, publiſhed their reaſons of diſſent, which were calculated to inflame a party already violent, and which, in fact, produced ſome diſturbances in the weſtern part of the ſtate.

In New Jerſey, the convention which met in December, were unanimous in adopting the conſtitution; as was likewiſe that of Georgia.

In Connecticut there was ſome oppoſition; but the conſtitution was, on the 9th of January, 1788, ratified by three-fourths of the votes in convention, and the minority peaceably acquieſced in the deciſion.

In Maſſachuſetts, the oppoſition was large and reſpectable. The convention, conſiſting of more than three hundred delegates, were aſſembled in January, and continued their debates with great candor and liberality, about five weeks. At length the queſtion was carried for the conſtitution by a ſmall majority; and the minority, with that manly condeſcenſion which becomes great minds, ſubmitted to the meaſure, and united to ſupport the government.

In New Hampſhire, the federal cauſe was for ſome time doubtful. The greateſt number of the delegates in convention, were at firſt on the ſide of the oppoſition; and ſome, who might have had their objections removed by the diſcuſſion of the ſubject, were inſtructed to reject the conſtitution. Although the inſtructions of conſtituents cannot, on the true principles of repreſentation, be binding upon a deputy, in any legiſlative aſſembly, becauſe his conſtituents are but a *part* of the ſtate, and have not heard the arguments and objections of the *whole*, whereas his act is to affect the *whole* ſtate, and therefore is to be directed by the ſenſe or wiſdom of the whole, collected in the legiſlative aſſembly; yet the delegates in the New Hampſhire convention conceived very erroneouſly, that the ſenſe of the freemen in the towns, thoſe little diſtricts, where no act of legiſlation can be performed, impoſed a reſtraint upon their own wills. An adjournment was therefore moved and carried. This gave the people opportunity to gain a further knowledge of the merits of the conſtitution, and at the ſecond meeting of the convention, it was ratified by a reſpectable majority.

In Maryland, ſeveral men of abilities appeared in the oppoſition, and were unremitted in their endeavours to perſuade the people that the propoſed plan of government

United States.

ment was artfully calculated to deprive them of their dearest rights; yet in convention it appeared that five-sixths of the voices were in favour of it.

In South Carolina, the opposition was respectable; but two-thirds of the convention appeared to advocate and vote for the constitution.

In Virginia, many of the principal characters opposed the ratification of the constitution with great abilities and industry. But after a full discussion of the subject, a small majority, of a numerous convention, appeared for its adoption.

In New York, two-thirds of the delegates in convention were, at their first meeting, determined to reject the constitution. Here therefore the debates were the most interesting, and the event extremely doubtful. The argument was managed with uncommon address and abilities on both sides of the question. But during the session, the ninth and tenth states had acceded to the proposed plan, so that by the constitution, Congress were empowered to issue an ordinance for organizing the new government. This event placed the opposition on new ground; and the expediency of uniting with the other states, the generous motives of conciliating all differences, and the danger of a rejection, influenced a respectable number, who were originally opposed to the constitution, to join the federal interest. The constitution was accordingly ratified by a small majority; but the ratification was accompanied here, as in Virginia, with a bill of rights, declaratory of the sense of the convention, as to certain great principles, and with a catalogue of amendments, which were to be recommended to the consideration of the new Congress, and the several state legislatures.

North Carolina met in convention in July, to deliberate on the new constitution. After a short session, they rejected it by a majority of one hundred and seventy-six against seventy-six. In November 1789, however, this state again met in convention, and ratified the constitution by a large majority.

Rhode Island was doomed to be the sport of a blind and singular policy. The legislature, in consistency with the measures which had been before pursued, did not call a convention, to collect the sense of the state upon the proposed constitution; but in an unconstitutional and absurd manner, submitted the plan of government to the consideration of the people. Accordingly it was brought before town-meetings, and in most of them rejected. In some of the large towns, particularly in Newport and Providence, the people collected and resolved, with great propriety, that they could not take up the subject; and that the proposition for embracing or rejecting the federal constitution, could come before no tribunal but that of the *state* in convention or legislature. On the 24th of May, 1790, a convention of this state met at Newport, and on the 29th, adopted the constitution by a majority of *two* only.

Vermont, in convention at Bennington, January 10th, 1791, ratified the constitution of the United States, by a great majority (R).

From the moment the proceedings of the general convention at Philadelphia transpired, the public mind was exceedingly agitated, and suspended between hope and fear, until nine states had ratified their plan of a federal government. Indeed the anxiety continued until Virginia and New York had acceded to the system. But this did not prevent the demonstrations of their joy, on the accession of each state.

On the ratification in Massachusetts, the citizens of Boston, in the elevation of their joy, formed a procession in honour of the happy event, which was novel, splendid and magnificent. This example was afterwards followed, and in some instances improved upon, in Baltimore, Charleston, Philadelphia, New Haven, Portsmouth and New York, successively. Nothing could equal the beauty and grandeur of these exhibitions. A ship was mounted upon wheels, and drawn through the streets; mechanics erected stages, and exhibited specimens of labour in their several occupations, as they moved along the road; flags with emblems, descriptive of all the arts and of the federal union, were invented and displayed in honour of the government; multitudes of all ranks in life assembled to view the splendid scenes; while sobriety, joy and harmony marked the brilliant exhibitions, by which the Americans celebrated the establishment of their empire.

On the 3d of March, 1789, the delegates from the eleven states which at that time had ratified the constitution, assembled at New York, where a convenient and elegant building had been prepared for their accommodation. On opening and counting the votes for President,

3 Q 2

(R) The following exhibits at one view, the order, time, &c. in which the several states ratified the federal constitution.

					Majority.
Delaware,	December	3,	1787,	unanimously,	
Pennsylvania,	December	13,		46 to 23	23
New Jersey,	December	19,		unanimously,	
Georgia,	January	2,	1788,	unanimously,	
Connecticut,	January	9,		128 to 40	88
Massachusetts,	February	6,		187 to 168	19
Maryland,	April	28,		63 to 12	51
South Carolina,	May	23,		149 to 73	76
New Hampshire,	June	21,		57 to 46	11
Virginia,	June	25,		89 to 79	10
New York,	July	26,		30 to 25	5
North Carolina,	November	27,	1789,	193 to 75	118
Rhode Island,	May	29,	1790,		2
Vermont,	January	10,	1791,	by a great majority	
Kentucky,					

dent, it was found that GEORGE WASHINGTON was *unanimoufly* elected to that dignified office, and that JOHN ADAMS was chofen Vice Prefident. The annunciation of the choice of the firft and fecond magiftrates of the United States, occafioned a general diffufion of joy among the friends to the union, and fully evinced that thefe eminent characters were the choice of the people.

On the 30th of April, 1789, George Wafhington was inaugurated Prefident of the United States of America, in the city of New York. The ceremony was performed in the open gallery of Federal Hall, in the view of many thoufand fpectators. The oath was adminiftered by Chancellor Livingfton. Several circumftances concurred to render the fcene unufually folemn—The prefence of the beloved Father and Deliverer of his country—the impreffions of gratitude for his paft fervices—the vaft concourfe of fpectators—the devout fervency with which he repeated the oath, and the reverential manner in which he bowed to kifs the facred volume—thefe circumftances, together with that of his being chofen to the moft dignified office in America, and perhaps in the world, by the unanimous voice of more than three millions of enlightened *freemen*, all confpired to place this among the moft auguft and interefting fcenes which have ever been exhibited on this globe. For feveral years after the eftablifhment of the new conftitution, the United States were happily diftinguifhed by affording a few materials for hiftory.

The deliberations of the legiflature of the union were marked with wifdom, and the meafures they adopted productive of great national profperity. The wife appointments to office, which in general were made—the eftablifhment of a revenue and judiciary fyftem, and of a national bank—the affumption of the debts of the individual ftates, and the encouragement given to manufactures, commerce, literature, and to ufeful inventions, opened the faireft profpects of the peace, union and increafing refpectability of the American States. Thefe profpects have been realized.

The account of the United States which is here prefented to our readers, is extracted from that valuable work, the American Univerfal Geography, by the Rev. Dr Morfe.—To give a regular hiftory, or even a fketch, of the progrefs of things under the adminiftration of the Federal government—of the wifdom and firmnefs exhibited by the Prefident and Congrefs, in their meafures in times the moft critical and trying—of the intrigues and collifions of contending parties—of the dangers, domeftic and foreign which we have fo happily efcaped—and of the exifting ftate of our political affairs, does not fall in with the plan of this work.

UNITY, a fettlement in Lincoln county, Diftrict of Maine, between the Weft Ponds, 7 or 8 miles weft of Sidney, oppofite to Vaffalborough, and 15 miles northweft of Hallowell. It lies on Sandy river, about 16 miles from its mouth.—*Morse.*

UNITY, a townfhip of New-Hampfhire, fituated in Chefhire county, a few miles north-eaft of Charlefton. It was incorporated in 1764, and contains 538 inhabitants.—*ib.*

UNITY *Town*, in Montgomery county, Maryland, lies 2 or 3 miles from Patuxent river, 11 from Montgomery court-houfe, and 24 N. of the city of Wafhington.—*ib.*

VOLCANIC *Ifland*, between Swallow Ifland and *Santa Cruz*, about 8 leagues north of the latter, in the Pacific Ocean, in which Mendana, in 1595, faw a volcano, which flamed continually. S. lat. 10 30.—*ib.*

VOLUNTOWN, a townfhip on the E. line of Connecticut, Windham county, E. of Plainfield, 19 miles N. E. of Norwich, and 26 S. W. of Providence. It was fettled in 1696, having been granted to volunteers in the Narraganfet war; hence its name. It was incorporated in 1719. It is 20 miles long, and between 3 and 4 broad, and has a large fwamp abounding with white pine, fufficient to fupply the neighbouring towns with materials for building.—*ib.*

VORTICES of Des Cartes are now juftly exploded; but being the fiction of a very fuperior mind, they are ftill an object of curiofity, as being the foundation of a great philofophical romance. According to the author of that romance, the whole of infinite fpace was full of matter; for with him matter and extenfion were the fame, and confequently there could be no void. This immenfity of matter he fuppofed to be divided into an infinite number of very fmall cubes; all of which, being whirled about upon their own centres, neceffarily gave occafion to the production of two different elements. The firft confifted of thofe angular parts which, having been neceffarily rubbed off, and grinded yet fmaller by their mutual friction, conftituted the moft fubtle and moveable part of matter. The fecond confifted of thofe little globules that were formed by the rubbing off of the firft. The interftices betwixt thefe globules of the fecond element were filled up by the particles of the firft. But in the infinite collifions, which muft occur in an infinite fpace filled with matter, and all in motion, it muft neceffarily happen that many of the globules of the fecond element fhould be broken and grinded down into the firft. The quantity of the firft element having thus been increafed beyond what was fufficient to fill up the interftices of the fecond, it muft, in many places, have been heaped up together, without any mixture of the fecond along with it. Such, according to Des Cartes, was the original divifion of matter. Upon this infinitude of matter thus divided, a certain quantity of motion was originally impreffed by the Creator of all things, and the laws of motion were fo adjufted as always to preferve the fame quantity in it, without increafe, and without diminution. Whatever motion was loft by one part of matter, was communicated to fome other; and whatever was acquired by one part of matter, was derived from fome other: and thus, through an eternal revolution from reft to motion, and from motion to reft, in every part of the univerfe, the quantity of motion in the whole was always the fame.

But as there was no void, no one part of matter could be moved without thrufting fome other out of its place, nor that without thrufting fome other, and fo on. To avoid, therefore, an infinite progrefs, he fuppofed that the matter which any body pufhed before it rolled immediately backwards to fupply the place of that matter which flowed in behind it; as we may obferve in the fwimming of a fifh, that the water which it pufhes before it immediately rolls backwards to fupply the place of what flows in behind it, and thus forms a fmall circle or vortex round the body of the fifh. It was in the fame manner that the motion originally impreffed by the Creator upon the infinitude of matter neceffarily produced in it an infinity of greater and fmaller vortices,

tices, or circular ſtreams: and the law of motion being ſo adjuſted as always to preſerve the ſame quantity of motion in the univerſe, thoſe vortices either continued for ever, or by their diſſolution gave birth to others of the ſame kind. There was thus at all times an infinite number of greater and ſmaller vortices, or circular ſtreams, revolving in the univerſe.

But whatever moves in a circle is conſtantly endeavouring to fly off from the centre of its revolution. For the natural motion of all bodies is in a ſtraight line. All the particles of matter therefore, in each of thoſe greater vortices, were continually preſſing from the centre to the circumference, with more or leſs force, according to the different degrees of their bulk and ſolidity. The larger and more ſolid globules of the ſecond element forced themſelves upwards to the circumference, while the ſmaller, more yielding, and more active particles of the firſt, which could flow even through the interſtices of the ſecond, were forced downwards to the centre. They were forced downwards to the centre notwithſtanding their natural tendency was upwards to the circumference; for the ſame reaſon that a piece of wood, when plunged in water, is forced upwards to the ſurface, notwithſtanding its natural tendency is downwards to the bottom; becauſe its tendency downwards is leſs ſtrong than that of the particles of water, which, therefore, if one may ſay ſo, preſs in before it, and thus force it upwards. But there being a greater quantity of the firſt element than what was neceſſary to fill up the interſtices of the ſecond, it was neceſſarily accumulated in the centre of each of theſe great circular ſtreams, and formed there the fiery and active ſubſtance of the ſun. For, according to that philoſopher, the ſolar ſyſtems were infinite in number, each fixed ſtar being the centre of one; and he is among the firſt of the moderns who thus took away the boundaries of the univerſe: even Copernicus and Kepler, themſelves, have confined it within what they ſuppoſed the vault of the firmament.

The centre of each vortex being thus occupied by the moſt active and moveable parts of matter, there was neceſſarily among them a more violent agitation than in any other part of the vortex, and this violent agitation of the centre cheriſhed and ſupported the movement of the whole. But among the particles of the firſt element, which fill up the interſtices of the ſecond, there are many, which, from the preſſure of the globules on all ſides of them, neceſſarily receive an angular form, and thus conſtitute a third element of particles leſs fit for motion than thoſe of the other two. As the particles, however, of this third element were formed in the interſtices of the ſecond, they are neceſſarily ſmaller than thoſe of the ſecond, and are therefore, along with thoſe of the firſt, urged down towards the centre, where, when a number of them happen to take hold of one another, they form ſuch ſpots upon the ſurface of the accumulated particles of the firſt element, as are often diſcovered by teleſcopes upon the face of that ſun which enlightens and animates our particular ſyſtem. Thoſe ſpots are often broken and diſpelled by the violent agitation of the particles of the firſt element, as has hitherto happily been the caſe with thoſe which have ſucceſſively been formed upon the face of our ſun. Sometimes, however, they encruſt the whole ſurface of that fire which is accumulated in the centre; and the communication betwixt the moſt active and the moſt inert parts of the vortex being thus interrupted, the rapidity of its motion immediately begins to languiſh, and can no longer defend it from being ſwallowed up and carried away by the ſuperior violence of ſome other like circular ſtream; and, in this manner, what was once a ſun becomes a planet. Thus the time was, according to the ſyſtem, when the Moon was a body of the ſame kind with the ſun, the fiery centre of a circular ſtream of ether, which flowed continually round her; but her face having been cruſted over by a congeries of angular particles, the motion of this circular ſtream began to languiſh, and could no longer defend itſelf from being abſorbed by the more violent vortex of the earth, which was then, too, a ſun, and which chanced to be placed in its neighbourhood. The moon therefore became a planet, and revolved round the earth. In proceſs of time, the ſame fortune, which had thus befallen the moon, befel alſo the earth; its face was encruſted by a groſs and inactive ſubſtance; the motion of its vortex began to languiſh, and it was abſorbed by the greater vortex of the ſun: but though the vortex of the earth had thus become languid, it ſtill had force enough to occaſion both the diurnal revolution of the earth, and the monthly motion of the moon. For a ſmall circular ſtream may eaſily be conceived as flowing round the body of the earth, at the ſame time that it is carried along by that great ocean of ether which is continually revolving round the ſun; in the ſame manner, as in a great whirlpool of water, one may often ſee ſeveral ſmall whirlpools, which revolve round centres of their own, and at the ſame time are carried round the centre of the great one. Such was the cauſe of the original formation and conſequent motions of the planetary ſyſtem. When a ſolid body is turned round its centre, thoſe parts of it which are neareſt, and thoſe which are remoteſt from the centre, complete their revolutions in one and the ſame time. But it is otherwiſe with the revolutions of a fluid: the parts of it which are neareſt the centre complete their revolutions in a ſhorter time than thoſe which are remoter. The planets, therefore, all floating in that immenſe tide of ether which is continually ſetting in from weſt to eaſt round the body of the ſun, complete their revolutions in a longer or a ſhorter time, according to their nearneſs or diſtance from him.

This bold ſyſtem was eminently fitted to captivate the imagination; and though fraught with contradictions and impoſſibilities, attempts have been made to revive it, even in this country, under different names. All thoſe ſyſtems which repreſent the motions of the heavenly bodies as being the effect of the phyſical agency of ethers, of air, of fire, and of light, of which the univerſe is conceived to be full, labour under the ſame difficulties with the Carteſian hypotheſis; and very few of them, if any, are ſo neatly put together. It is ſurely ſufficient, however, to demoliſh this goodly fabric, barely to aſk how an abſolute infinity of matter can be divided into cubes, or any thing elſe? how there can poſſibly be interſtices in a perfect plenum? or how in ſuch a plenum any portion of matter can be thruſt from its place?

UPATCHAWANAN, or *Temiſcamain*, a Canadian ſettlement in N. America, in lat. 47 17 30 north.—*Morſe.*

UPPER ALLOWAYS *Creek*, in Salem county, New-Jerſey.—*ib.*

UPPER BALD EAGLE, a townſhip of Pennſylvania, in Mifflin county.—*ib.*

UPPER DISTRICT, a diviſion of Georgia, which contains the counties of Montgomery, Waſhington, Hancock, Greene, Franklin, Oglethorpe, Elbert, Wilkes, Warren, Columbia, and Richmond.—*ib.*

UPPER DUBLIN, a townſhip of Pennſylvania, in Montgomery county.—*ib.*

UPPER FREEHOLD, a townſhip of New-Jerſey, Monmouth county, adjoining to Burlington and Middleſex counties on the north and ſouth-weſt, and Freehold on the eaſt. It contains 3,442 inhabitants.—*ib.*

UPPER GREAT MONADNOCK, in the townſhip of Lemington, in the north eaſt corner of Vermont, on Connecticut river.—*ib.*

UPPER HANOVER, a townſhip of Pennſylvania, Montgomery county.—*ib.*

UPPER MARLBOROUGH, a poſt-town of Maryland, 16 miles ſouth-eaſt of Bladenſburg, 15 north-eaſt of Piſcataway, and 162 ſouth-weſt of Philadelphia.—*ib.*

UPPER MILFORD, a townſhip of Pennſylvania, Northampton county.—*ib.*

UPPER PENN'S NECK, a townſhip of New-Jerſey, Salem county.—*ib.*

UPPER SAURA, a place in North-Carolina, on Dan river, about 200 miles from Halifax.—*ib.*

UPPER SAVAGE *Iſlands*, in Hudſon's Bay. N. lat. 62 32 30, W. long. 70 48.—*ib.*

UPTON, a townſhip of Maſſachuſetts, Worceſter county, containing 900 inhabitants, diſperſed on 13,000 acres of land, favourable for orcharding, paſturage and graſs. It is weſt of Sherburne in Middleſex county, 15 miles ſouth-eaſt of Worceſter, and 38 ſouth-weſt of Boſton.—*ib.*

UPRIGHT *Bay*, near the weſt end of the Straits of Magellan. S. lat. 53 8, W. long. 75 35.—*ib.*

URACHO, a river on the eaſt coaſt of South-America, is 18 leagues W. N. W. of Caurora river.—*ib.*

URAGUA, a province in the eaſt diviſion of Paraguay, in South-America, whoſe chief town is Los Reyes.—*ib.*

URALIAN COSSACS, a people that inhabit the Ruſſian province of Orenburg in Aſia, on the ſouth ſide of the river Ural. Theſe Coſſacs are deſcended from thoſe of the Don: they are a very valiant race. They profeſs the Greek religion; but there is a kind of diſſenters from the eſtabliſhed religion, whom the Ruſſians called *Roſkolniki*, or Separatiſts, and who ſtyle themſelves *Staroverſki*, or Old Believers. They conſider the ſervice of the eſtabliſhed church as profane and ſacrilegious, and have their own prieſts and ceremonies. The Uralian Coſſacs are all enthuſiaſts for the ancient ritual, and prize their beards almoſt equal to their lives. A Ruſſian officer having ordered a number of Coſſac recruits to be publicly ſhaved in the town of Yaitſk, in 1771, this wanton inſult excited an inſurrection, which was ſuppreſſed for a time; but, in 1773, that daring impoſtor, Pugatchef, having aſſumed the name and perſon of Peter III. appeared among them, and taking advantage of this circumſtance, and of their religious prejudices, rouſed them once more into open rebellion. This being at laſt effectually ſuppreſſed by the defeat and execution of the impoſtor (See Suworow, *Suppl.*), in order to extinguiſh all remembrance of this rebellion, the river Yaik was called *Ural;* the Yaic Coſſacs were denominated *Uralian Coſſacs;* and the town of Yaitſk, *Uralſk.* The Uralian Coſſacs enjoy the right of fiſhing on the coaſt of the Caſpian Sea, for 47 miles on each ſide of the river Ural. Their principal fiſhery is for ſturgeons and beluga, whoſe roe ſupplies large quantities of caviare; and the fiſh, which are chiefly ſalted and dried, afford a conſiderable article of conſumption in the Ruſſian empire. In conſequence of theſe fiſheries, theſe Coſſacs are very rich.

URANO, a river on the north coaſt of S. America, which enters the ocean abreaſt of the weſternmoſt of the Peritas Iſlands, about 3 leagues weſtward of Comana Bay. It only admits ſmall boats and canoes. Otchier Bay is to the weſt of it.—*Morſe.*

URBANNA, a ſmall poſt-town of Virginia, Middleſex county, on the ſouth-weſt ſide of Rappahannock river, 22 miles from Stingray Point, at the mouth of the river, 73 ſouth-eaſt of Fredericksburg, 73 eaſt by ſouth of Richmond, 28 from Tappahannock, and 291 from Philadelphia. Wheat is ſhipped from this to Europe, and Indian corn, &c. to New-England, Nova-Scotia, and the Weſt-Indies.—*ib.*

URBINO, a town of Italy, in the territory of the Pope, and capital of the duchy of Urbino, with an old citadel, an archbiſhop's ſee, and a handſome palace, where the dukes formerly reſided. The houſes are well built, and great quantities of fine earthen ware are made here. It is ſeated on a mountain, between the rivers Metro and Foglia, 18 miles ſouth of Rimini, 58 eaſt of Florence, and 120 north-eaſt of Rome. E. Lon. 12. 40. N. lat. 43. 46.

URBINO, a duchy of Italy, in the territory of the church, bounded on the north by the gulph of Venice; on the ſouth, by Perugino and Umbria; on the eaſt, by the marquiſate of Ancona; and on the weſt, by Tuſcany and Romagna. It is about 55 miles in length, and 45 in breadth. Here is great plenty of game and fiſh; but the air is not very wholeſome, nor is the ſoil fertile. Urbino is the capital.

URCEOLA, a lately diſcovered genus of the *pentandria* claſs, and *monogynia* order of plants, ranking immediately after TABERNÆ MONTANA (ſee *Encycl.*), and conſequently belonging to the 30th natural order or claſs called *Contortæ* by Linnæus in his natural method of arrangement. One of the qualities of the plants of this order is their yielding, on being cut, a juice which is generally milky, and for the moſt part deemed of a poiſonous nature. The genus is thus characteriſed by Dr Roxburgh; *Calyx* beneath five-toothed; corol one petaled, pitcher-ſhaped, with its contracted mouth five-toothed: nectary entire, ſurrounding the germs; follicles two, round, drupacious; ſeeds numerous, immerſed in pulp. There is but one known ſpecies, which is thus deſcribed by the ſame eminent botaniſt;

URCEOLA ELASTICA: Shrubby, twining, leaves oppoſite, oblong, panicles terminal, is a native of Sumatra, Prince of Wales's Iſland, &c. Malay countries. *Stem* woody, climbing over trees, &c. to a very great extent, young ſhoots twining, and a little hairy, bark of the old woody parts thick, dark coloured, conſiderably uneven, a little ſcabrous, on which are found ſeveral ſpecies of moſs, particularly large patches of lichen; the wood is white, light and porous. *Leaves* oppoſite, ſhort-petioled, horizontal, ovate, oblong, pointed, entire, a little ſcabrous, with a few ſcattered white hairs on the under

under fide. *Stipulus* none. *Panicles* terminal, brachiate, very ramous. *Flowers* numerous, minute, of a dull greenifh colour, and hairy on the outfide. *Bracts* lanceolate, one at each divifion and fubdivifion of the panicle. *Calyx* perianth, one-leafed, five-toothed, permanent. *Corol* one petaled, pitcher-fhaped, hairy, mouth much contracted, five-toothed, divifions erect, acute, nectary entire, cylindric, embracing the lower two-thirds of the germs. *Stamens*, filaments five, very fhort from the bafe of the corol. Anthers arrow-fhaped, converging, bearing their pollen in two grooves on the infide, near the apex; between thefe grooves and the infertions of the filaments they are covered with white foft hairs. *Piftil*, germs two; above the nectary they are very hairy round the margins of their truncated tops. Style fingle, fhorter than the ftamens. Stigma ovate, with a circular band, dividing it into two portions of different colours. *Per.* Follicles two, round, laterally compreffed into the fhape of a turnip, wrinkled, leathery, about three inches in their greateft diameters—one celled, two valved. *Seeds* very numerous, reniform, immerfed in firm flefhy pulp.

See Plate XLVII. where fig. 1. is a branchlet in flower of the natural fize. 2. A flower magnified. 3. The fame laid open, which expofes to view the fituation of the ftamens inferted into the bottom of the corol, the nectarium furrounding the lower half of the two germs, their upper half with hairy margins, the ftyle and ovate party coloured; ftigma appearing above the nectary. 4. Outfide of one of the ftamens; and, 5. Infide of the fame, both much magnified. 6. The nectarium laid open, expofing to view the whole of the piftil. 7. The two feed veffels (called by Linnæus *follicles*), natural fize; half of one of them is removed, to fhew the feed immerfed in pulp. A portion thereof is alfo cut away, which more clearly fhews the fituation and fhape of the feed.

From wounds made in the bark of this plant there oozes a milky fluid, which on expofure to the open air feparates into an elaftic coagulum, and watery liquid, apparently of no ufe, after the feparation takes place. This coagulum is not only like the American caoutchouc or Indian rubber, but poffeffes the fame properties; for which, fee CAOUTCHOUC, both in the *Encycl.* and *Suppl.*

The chemical properties of this vegetable milk, while frefh, were found by Mr Howifon, late furgeon on Prince of Wales's Ifland, furprifingly to refemble thofe of animal milk. From its decompofition, in confequence of fpontaneous fermentation, or by the addition of acids, a feparation takes place between its cafeous and ferous parts, both of which are very fimilar to thofe produced by the fame proceffes from animal milk. An oily or butyrous matter is alfo one of its component parts, which appears upon the furface of the gum fo foon as the latter has attained its folid form. He endeavoured to form an extract of this milk fo as to approach to the confiftence of new butter, by which he hoped to retard its fermentative ftage, without depriving it of its ufeful qualities; but as he had no apparatus for diftilling, the furface of the milk, that was expofed to the air, inftantly formed into a folid coat, by which the evaporation was in a great degree prevented. He, however, learned, by collecting the thickened milk from the infide of the coats, and depofiting it in a jelly pot, that, if excluded from the air, it might be preferved in this ftate for a confiderable length of time; and even without any preparation he kept it in bottles, tolerably good, upwards of twelve months.

URINARY CONCRETIONS. See *Animal* SUBSTANCES, Suppl.

URTICA. See *Encycl.* where it is obferved that the common nettle, though it has a place in the *materia medica*, is now very little ufed. It has lately been recommended, however, by *Zannetini*, a phyfician who attended the French army in Italy, as a good fubftitute in fevers for cinchona. The fuccefs of fome experiments, which he made with it in tertian and quartan malignant fevers, furpaffed, he fays, his moft fanguine expectation. The nettle often produces a fpeedier effect than bark; for it heats in a great degree, and when the dofe is pretty ftrong, occafions a lethargic fleep. The dofe muft never exceed a dram, and is given in wine two or three times in the courfe of 24 hours. Zannetini found this medicine of great fervice to guard againft that total exhauftion which forms the principal character of malignant fevers; and he recommends a flight infufion of it in wine as an excellent prefervative for thofe who refide in marfhy and infalubrious diftricts. In employing the nettle in fever, Zannetini gives the fame caution as ought to be obferved in regard to cinchona, that is, that it muft not be employed where there is an inclination to inflammation, or where a continued fever, arifing from obftructions, exifts. This difcovery is not unworthy the attention of phyficians, and deferves at leaft to be farther inveftigated, as a great deal would be faved if cinchona could be entirely difpenfed with.

URVAIG, or *Urvaiga*, a province of South-America; bounded by Guayra on the north, the mouth of Rio de la Plata on the fouth, the captainry of del Rey on the eaft, and Parana on the weft, from which it is divided by the river of that name. Its extent is from lat. 25 to 33 20 fouth; the length from north-eaft to fouth-eaft being fomewhat above 210 leagues, and the breadth from eaft to weft, where broadeft, 130, but much narrower in other parts. It is divided by the river Urvaiga, or Uruguay, into the eaft and weft parts. This river runs above 400 leagues, the upper part with a prodigious noife among rocks and ftones, and falls into the La Plata almoft oppofite to Buenos Ayres.—*Morse.*

UTAWAS, a river which divides Upper and Lower Canada, and falls into Jefus Lake, 118 miles fouth-weft of Quebec. It receives the waters of Timmifkamain 360 miles from its mouth: 85 miles above it is called Montreal river.—*ib.*

UTRECHT, *New*, a townfhip of New-York, King's county, Long-Ifland. It has a Dutch church, and contains 562 inhabitants; of whom 76 are electors, and 206 are flaves. It is 7 or 8 miles fouthward of New-York city.—*ib.*

UXBRIDGE, a townfhip of Maffachufetts, Worcefter county, 41 miles fouth-weft of Bofton. It was taken from Mendon, and incorporated in 1727, and Northbridge was afterwards taken from it. It contains 180 dwelling houfes, and 1,308 inhabitants. It is bounded fouth by the State of Rhode-Ifland. Not far from Shoe-log Pond, in the fouth-weft part of the town, there is an iron mine which is improved to confiderable advantage.—*ib.*

W.

WABASH is a beautiful navigable river, of the N. W. Territory, which runs a S. W. and southern course, and empties into the Ohio, by a mouth 270 yards wide, in lat. 37 41 N. 168 miles from the mouth of the Ohio, and 1022 miles below Pittsburg. In the spring, summer, and autumn, it is passable in batteaux and barges, drawing about 3 feet water, 412 miles, to Ouiatanon; and for large canoes 197 miles further, to the Miami carrying place, 9 miles from Miami village. This village stands on Miami river, which empties into the S. W. part of Lake Erie. The communication between Detroit and the Illinois and Ohio countries, is up Miami river, to Miami village, thence by land 9 miles, when the rivers are high, and from 18 to 30 when they are low, through a level country to the Wabash, and through the various branches of the Wabash to the places of destination. The land on this river is remarkably fertile. A silver mine has been discovered about 28 miles above Ouiatanon, on the northern side of the Wabash. Salt springs, lime, free-stone, blue, yellow, and white clay, are found in plenty on this river. The copper mine on this river, is perhaps the richest vein of native copper in the bowels of the whole earth.—*Morse.*

WABASH, *Little*, runs a course S. S. E. and falls into the Wabash 10 miles from the Ohio.—*ib.*

WACHOVIA, or *Dobb's Parish*, a tract of land in N. Carolina, situated between the E. side of Yadkin river, and the head waters of Haw and Deep rivers, consisting of about 100,000 acres, partly in Stokes and Surry counties. The United Brethren, or Moravians, purchased this tract of Lord Granville, in 1751, and called it Wachovia, after the name of an estate of Count Zinzendorf, in Germany. In 1755, it was made a separate parish, and named Dobb's, by the legislature. The settlement of Bethabara, was begun in 1753, by a number of the Brethren from Pennsylvania. Salem, which is the principal settlement, commenced in 1766, and is inhabited by a number of ingenious tradesmen. This thriving parish lies about 10 miles S. of Pilot Mountain, and contains 6 churches. —*ib.*

WACHQUATNACH, an ancient Moravian settlement in Connecticut, on Stratford river; 23 miles from its mouth.—*ib.*

WACHUSET *Mountain*, in the town of Princetown, Massachusetts, may be seen in a clear horizon, at the distance of 67 miles, being 2,989 feet above the level of the sea.—*ib.*

WADESBOROUGH, the chief town of Anson county, in Fayetteville district, N. Carolina. It contains a court-house, gaol, and about 30 houses, and being seated on a lofty hill, is both pleasant and healthy. It is 76 miles west by south of Fayetteville, and 50 south-east by S. of Salisbury.—*ib.*

WADMELAW, an island in Charleston harbour, S. Carolina.—*ib.*

WADSWORTH, a town of New-York, Ontario county, situated on the east bank of Genessee river; 4 miles west of Conesus Lake, and 13 south-west by south of Hartford.—*ib.*

WADHAM *Islands*, near the N. E. coast of Newfoundland Island. N. lat. 49 57, west long. 53 37. —*ib.*

WAGER's *Strait*, or *River*, in New North Wales, in N. America, lies in lat. 65 23 N. and is about 2 or 3 miles wide. At 5 or 6 miles within its entrance, it is 6 or 8 leagues wide, having several islands and rocks in the middle. It has soundings from 16 to 30 and 44 fathoms; and the land on both sides is as high (according to Captain Middleton's account) as any in England. Savage Sound, a small cove or harbour, fit for ships to anchor in, lies on the northern shore, 13 or 14 leagues up the strait, in long. 87 18 W. All the country from Wager's Strait to Seal river, is in some maps called New Denmark. Capt. Monk was sent thither, in 1610, by the king of Denmark, and wintered at a place called Monk's Winter Harbour, in lat. 63 20 N. which must be a little north of Rankin's Inlet.—*ib.*

WAGER's *Strait*, in N. America, is in about lat. 65 37 N. When Capt. Ellis was in this latitude, the tide ran at the rate of from 8 to 10 leagues an hour. He compares it to the sluice of a mill.—*ib.*

WAITSFIELD, the south-easternmost township of Chittenden county, Vermont, containing 61 inhabitants.—*ib.*

WAIT's *River* rises in Orange county, Vermont, and empties into Connecticut river, at Bradford.—*ib.*

WAJOMICK, an Indian town on Susquehannah river, about 400 miles from the sea. In the spring of 1756, the Indians shot 2 seals here, and they could not sufficiently express their astonishment at the sight of these animals unknown to them.—*ib.*

WAKE, an inland county of Hillsborough district, North-Carolina; bounded N. W. by Orange, and E. and S. E. by Johnson. It contains 10,192 inhabitants, including 2,463 slaves. Chief town, Raleigh.—*ib.*

WAKEFIELD, formerly *East town* and *Watertown*, a township of Strafford county, New-Hampshire, east of Wolfborough, incorporated in 1774. It contains 640 inhabitants. In the north-east part is a pond which is the source of Piscataqua river.—*ib.*

WAKKAMAW, a beautiful lake, 26 miles in circuit, situated in Bladen county, North-Carolina. The lands on its eastern shores are fertile, and the situation delightful, gradually ascending from the shores; bounded on the north-west coast by vast rich swamps, fit for rice. This lake is the source of a fine river, of the same name, and runs a southerly course, for 70 or 80 miles, and empties into Winyaw Bay, at Georgetown, in South-Carolina.—*ib.*

WALDEN, a township of Vermont, Caledonia county, having Danville on the south-east. It contains only 11 inhabitants.—*ib.*

WALDOBOROUGH, a post-town and port of entry of the District of Maine, in Lincoln county, 12 miles S. by W. of Warren, 10 E. by S. of Newcastle, 20 eaſt of Wiſcaſſet, and 545 north-eaſt of Philadelphia. This is the port of entry for the diſtrict, lying between the towns of Camden and Northport; and all the ſhores and waters from the middle of Damariſcotta river to the ſouth-weſtern ſide of the town of Northport. The townſhip of Waldoborough was incorporated in 1773, and contains 1210 inhabitants.—*ib.*

WALDO *Patent*, a tract of land forming the ſouth-eaſt part of Hancock county in the Diſtrict of Maine, and on the weſt ſide of Penobſcot river and bay.—*ib.*

WALES, New South, is a country which muſt be intereſting on account of the ſingular colony which was ſettled there in the year 1788. Under the title *New Holland* (*Encycl.*) ſome account has been given of that ſettlement, as well as of the climate and the ſoil about Port Jackſon; but it will probably gratify the curioſity of our readers, if we give a ſhort hiſtory of thoſe European ſettlers, of whom it is to be hoped that they carried not with them, to that diſtant ſhore,

"Minds not to be changed by time or place."

This hiſtory we ſhall take from the accurate *Account of the Engliſh Colony in New South Wales*, by David Collins, Eſq; who went out with Governor Phillip, and continued to execute the offices of Judge-advocate and Secretary till the cloſe of the year 1796; and we ſhall begin our narrative from the diſembarkation of the firſt coloniſts, when his Majeſty's commiſſion to the governor, and the letters patent eſtabliſhing courts of criminal and civil judicature in the territory were read.

The criminal court was conſtituted a court of record, and was to conſiſt of the judge-advocate and ſuch ſix officers of the ſea and land ſervice as the governor ſhall, by precept iſſued under his hand and ſeal, require to aſſemble for that purpoſe. This court has power to inquire of, hear, determine, and puniſh all treaſons, miſpriſions of treaſons, murders, felonies, forgeries, perjuries, treſpaſſes, and other crimes whatſoever that may be committed in the colony; the puniſhment for ſuch offences to be inflicted according to the laws of England as nearly as may be, conſidering and allowing for the circumſtances and ſituation of the ſettlement and its inhabitants. The charge againſt any offender is to be reduced into writing, and exhibited by the judge-advocate: witneſſes are to be examined upon oath, as well for as againſt the priſoner; and the court is to adjudge whether he is guilty or not guilty by the opinion of the major part of the court. If guilty, and the offence is capital, they are to pronounce judgment of death, in like manner as if the priſoner had been convicted by the verdict of a jury in England, or of ſuch corporal puniſhment as the court, or the major part of it, ſhall deem meet. And in caſes not capital, they are to adjudge ſuch corporal puniſhment as the majority of the court ſhall determine. But no offender is to ſuffer death unleſs five members of the court ſhall concur in adjudging him to be guilty, until the proceedings ſhall have been tranſmitted to England, and the king's pleaſure ſignified thereupon. The provoſt-marſhal is to cauſe the judgment of the court to be executed according to the governor's warrant under his hand and ſeal.

Beſide this court for the trial of criminal offenders, there is a civil court, conſiſting of the judge-advocate and two inhabitants of the ſettlement, who are to be appointed by the governor; which court has full power to hear and determine in a ſummary way all pleas of lands, houſes, debts, contracts, and all perſonal pleas whatſoever.

Wales.

From this court on either party, plaintiff or defendant, finding himſelf or themſelves aggrieved by the judgment or decree, an appeal lies to the governor, and from him, where the debt or thing in demand ſhall exceed the value of L. 300, to the king in council.

A vice-admiralty court was alſo appointed, for the trial of offences on the high ſeas; and the governor, lieutenant-governor, and judge-advocate, were by patent made juſtices of the peace, with a power in the governor to appoint other juſtices.

The ſituation which Governor Phillip had ſelected for his reſidence, and for the principal ſettlement, was the eaſt ſide of a cove in Port Jackſon, which he called *Sydney Cove.* Its latitude was found to be 33° 52′ 30′ ſouth, and its longitude 152° 19′ 30″ eaſt. This ſituation was choſen without due examination; for it ſoon appeared that the head or upper part of the cove wore a much more favourable appearance than the ground immediately about the ſettlement. From the natives, the new ſettlers met no oppoſition; during the firſt ſix weeks they received only one viſit from them, two men ſtrolling one evening into the camp, and remaining in it for about half an hour. They appeared to admire whatever they ſaw; and after receiving a hatchet (of the uſe of which the eldeſt inſtantly and curiouſly ſhewed his knowledge, by turning up his foot and ſharpening a piece of wood on the ſole with the hatchet) took their leave, apparently well pleaſed with their reception. The fiſhing boats alſo frequently reported their having been viſited by many of theſe people when hauling the ſeine; at which labour they often aſſiſted with cheerfulneſs, and in return were generally rewarded with a part of the fiſh taken.

The firſt labour in which the convicts were employed was that of building huts; and for this purpoſe it was found neceſſary to divide them into gangs, and to appoint an overſeer to each, who ſhould ſee that the proper quantity of work was performed. The proviſions were diſtributed by a weekly ration, and to each man were allowed 7lb. of biſcuit, 1lb. of flour, 7lb. of beef or 4lb. of pork, 3 pints of peaſe, and 6 ounces of butter. To the female convicts two-thirds of this ration were allowed. This was the full ration, which, in many inſtances, it became neceſſary to reduce; and once, in conſequence of the delay of tranſports with a ſupply, the convicts were put on an allowance of which fleſh meat conſtituted no part.

The temporary huts in which the coloniſts lived, for ſome time after their arrival, were formed principally of the cabbage-tree. With this the ſides and ends were filled; the poſts and plates being made of the pine; and the whole was plaſtered with clay. The roofs were generally thatched with the graſs of the gumruſh; though ſome were covered with clay, but ſeveral of theſe failed; the weight of the clay and rain ſoon deſtroying them. In a ſhort time they applied themſelves to the burning of bricks; by which their habitations ſoon became much more laſting and comfortable. The progreſs of the colony, however, towards that degree of convenience which was within its reach, was greatly impeded by the incorrigible vices of thoſe who principally

Wales. pally compoſed it. Drunkenneſs, theft, robbery, and unconquerable lazineſs, continued to mark the character of the great body of the convicts. Though to fly from the colony, and venture into the interior of the country, was inevitable death in the form of famine or of murder, yet ſuch was the invincible antipathy to labour manifeſted by ſome of thoſe people, that they often fled to the woods, from which they ſeldom returned; ſome dying of hunger, and ſome being ſacrificed by the natives. Diſinclination to labour produced here, as elſewhere, its natural effect—robbery.

In the month of May 1788, a lad of 17 years of age was tried, convicted, and executed, for breaking open a tent belonging to one of the tranſport ſhips; ſeveral others were taken into cuſtody in that month for various thefts and burglaries, and two were afterward tried and executed. One of theſe had abſconded, and lived in the woods for 19 days, ſubſiſting by what he was able to procure by nocturnal depredations among the huts and ſtock of individuals. His viſits for this purpoſe were ſo frequent and daring, that it became abſolutely neceſſary to proclaim him an outlaw. By the negligence of one of thoſe fellows who had been intruſted with the care of the cattle, the bull and four cows were loſt: he left them in the fields, and returned to his hut to dine; and in the mean time they either ſtrayed away or were driven off by the natives. Five years elapſed before theſe cattle were diſcovered wild, at a conſiderable diſtance up the country, and greatly multiplied.

The perpetration of crimes, chiefly theft and robbery, had become ſo prevalent before twenty months had paſſed ſince the colony was eſtabliſhed, that it was neceſſary to think of a ſyſtem of police. A plan was preſented to the governor by a *convict*, which with ſome improvements was adopted on the 8th of Auguſt 1789. The following are the heads of the arrangement.

The ſettlement was divided into four diſtricts, over each of which was placed a watch conſiſting of three perſons, one principal and two ſubordinate watchmen. Theſe being ſelected from among thoſe convicts whoſe conduct and character had been unexceptionable ſince their landing, were veſted with authority to patrole at all hours in the night, to viſit ſuch places as might be deemed requiſite for the diſcovery of any felony, treſpaſs, or miſdemeanor, and to ſecure for examination all perſons that might appear to be concerned therein; for which purpoſe they were directed to enter any ſuſpected hut or dwelling, or to uſe any other means that might appear expedient. They were required to detain and give information to the neareſt guardhouſe of any ſoldier or ſeaman who ſhould be found ſtraggling after the tattoo had been beat. They were to uſe their utmoſt endeavours to trace out offenders on receiving accounts of any depredation; and in addition to their night-duty, they were directed to take cognizance of ſuch convicts as gamed, or ſold or bartered their ſlops or proviſions, and report them for puniſhment. A return of all occurrences during the night was to be made to the judge-advocate; and the military were required to furniſh the watch with any aſſiſtance they might be in need of, beyond what the civil power could give them. They were provided each with a ſhort ſtaff, to diſtinguiſh them during the night, and to denote their office in the colony; and were inſtructed not to receive any ſtipulated encouragement or reward from any individual for the conviction of offenders, but to expect that negligence or miſconduct in the execution of their truſt would be puniſhed with the utmoſt rigour. It was to have been wiſhed, ſays Mr Collins, that a watch eſtabliſhed for the preſervation of public and private property had been formed of free people, and that neceſſity had not compelled us, in ſelecting the firſt members of our little police, to appoint them from a body of men, in whoſe eyes, it could not be denied, the property of individuals had never before been ſacred. But there was not any choice: The military had their line of duty marked out for them, and between them and the convict there was no deſcription of people from whom overſeers or watchmen could be provided. It might, however, be ſuppoſed, that among the convicts there muſt be many who would feel a pride in being diſtinguiſhed from their fellows, and a pride that might give birth to a returning principle of honeſty. It was hoped that the convicts whom we had choſen were of this deſcription; ſome effort had become neceſſary to detect the various offenders who were prowling about with ſecurity under cover of the night; and the convicts who had any property were themſelves intereſted in defeating ſuch practices. They promiſed fidelity and diligence, from which the ſcorn of their fellow-priſoners ſhould not induce them to ſwerve, and began with a confidence of ſucceſs the duty which they had themſelves offered to undertake.

A ſpecies of diſturber now infeſted the colony, againſt which the vigilance of a police could not guard. Rats, in immenſe numbers, had attacked the proviſion ſtores, and could be counteracted only by removing the proviſions from one ſtore to another. When their ravages were firſt diſcovered, it was found that eight caſks of flour were already deſtroyed by theſe vermin. Such of theſe animals as eſcaped the dogs, which were ſet upon them, flew to the gardens of individuals, where they rioted on the Indian corn that was growing, and did conſiderable miſchief.

Our author gives the moſt melancholy account of the extreme ſufferings of the early coloniſts from want of proviſions, and of the diſeaſes imported into the country by newcomers, who had either caught them on the voyage or brought them from England. The ſettlers on Norfolk-*Iſland* (ſee *Encycl.*), to which New South Wales was a mother country, muſt have been much more liable than that colony to ſuffer from famine, had they not ſometimes obtained a temporary ſupply from a ſource which was unknown at Sydney Cove. On a mountain in the iſland, to which had been given the name of *Mount Pitt*, they were fortunate enough to obtain in an abundance almoſt incredible, a ſpecies of aquatic birds, anſwering the deſcription of that known by the name of the *puffin*. Theſe birds came in from the ſea every evening, in clouds literally darkening the air, and deſcending on Mount Pitt, depoſited their eggs in deep holes made by themſelves in the ground, generally quitting them in the morning, and returning to ſeek their ſubſiſtence in the ſea. From two to three thouſand of theſe birds were often taken in a night. Their ſeeking their food in the ocean left no doubt of their own fleſh partaking of the quality of that upon which they fed; but to people circumſtanced as were the inhabitants of Norfolk-iſland, this leſſened not their importance; and while any Mount Pitt birds (ſuch be-

ing

Wales. ing the name given them) were to be had, they were eagerly sought.

The first settler in New South Wales, who declared himself able to live on the produce of his farm, without any assistance from the stores, was James Ruse; who in April 1790 relinquished his claim to any farther share of the public provision. As a reward, the governor immediately put him in possession of an allotment of 30 acres.

In the July of the same year, the convicts whose terms of transportation had expired were now collected, and by the authority of the governor informed, that such of them as wished to become settlers in this country should receive every encouragement; that those who did not, were to labour for their provisions, stipulating to work for 12 or 18 months certain; and that in the way of such as preferred returning to England no obstacles would be thrown, provided they could procure passages from the masters of such ships as might arrive; but that they were not to expect any assistance on the part of government to that end. The wish to return to their friends appeared to be the prevailing idea, a few only giving in their names as settlers, and none engaging to work for a certain time.

That the wish to return home was strong indeed, and paramount to all other feelings, was evinced in a very melancholy instance some time before. A convict, an elderly man, was found dead in the woods, near the settlement; who, on being opened, it appeared had died from want of nourishment; and it was found that he was accustomed to deny himself even what was absolutely necessary to his existence, abstaining from his provisions, and selling them for money, which he was reserving, and had somewhere concealed, in order to purchase his passage to England when his time should terminate!

Of some convicts whose terms of transportation had expired, the governor established a new settlement in August 1791, at a place which he called *Prospect Hill*, about twenty miles distant from Sydney Cove; and another residence was formed at the Ponds within three or four miles of the former. This made the fourth settlement in the colony, exclusively of that at Norfolk Island.

About this time the governor received from England a public seal for the colony: on the obverse of which were the king's arms and royal titles; and on the reverse, emblematic figures suited to the situation of the people for whose use it was designed. The motto was "*Sic fortis Etruria crevit*;" and in the margin were the words "*Sigillum Nov. Camb. Aust.*" A commission also arrived, empowering him to remit absolutely, or conditionally, the whole or any part of the term for which the felons sent to the colony might be transported. By this power he was enabled to bestow on superior honesty and industry the most valuable reward which, in such circumstances, they could receive.

In addition to the calamities under which the settlement had so often laboured from being reduced to very short allowance of provisions, and the frequency of the ordinary diseases which were to be expected among a people so situated, a new malady of a very alarming nature was perceived about April 1792. Several convicts were seized with insanity; and as the major part of those who were visited by this calamity were females, who, on account of their sex, were not harrassed with hard labour, and who in general shared largely of such little comforts as were to be procured in the settlement, it was difficult to assign a cause for this disorder. It seems, however, to have been of short duration; for we hear not of it again during the period that Mr Collins's narrative comprehends.

About this time (1792) the colony had assumed something of an established form. Brick huts were in hand for the convicts in room of the miserable hovels occupied by many, which had been put up at their first landing, and in room of others which, from having been erected on such ground as was then cleared, were now found to interfere with the direction of the streets which the governor was laying out. People were also employed in cutting paling for fencing in their gardens. At a place called Paramatta, about 16 miles from Sydney Cove, situated on a small river which runs into Port Jackson, the people were employed, during the greatest part of the month of May, in getting in the maize and sowing wheat. A foundation for an hospital was laid, a house built for the master carpenter, and roofs prepared for the different huts either building or to be built in future.

In December 1792, when Captain Phillip resigned the government, nearly five years from the foundation of the colony, there were in cultivation at the different settlements 1429 acres, of which 417 belonged to settlers; that is, 67 settlers, for there were no more, cultivated nearly half as much ground as was cultivated by the public labour of all the convicts; a striking proof of the superior zeal and diligence with which men exert themselves when they have an interest in their labour. Of free settlers, whose exertions promised so fairly to promote the interests of the colony, several arrived from England in January 1793, and fixed themselves in a situation which they called *Liberty Plains*. To one of these, Thomas Rose, a farmer from Dorsetshire, and his family of a wife and four children, 120 acres were allotted. The conditions under which these people agreed to settle were, "to have their passage provided by government (A); an assortment of tools and implements to be given to them out of the stores; that they should be supplied with two years provisions; that their lands should be granted free of expense; the service of convicts also to be assigned to them free of expense; and that those convicts should be supplied with two years rations and one year's clothing."

Among the great difficulties with which this infant establishment had to struggle, not the least was that of procuring cattle. Of those which were embarked in England and other places for the colony, a very small proportion only arrived; for of 15 bulls and 119 cows, which had been embarked for Botany Bay, only 3 bulls and 28 cows were landed at the settlement. It was not until the arrival of the Endeavour, Captain Bampton, in 1795, that the mode of conveying cattle to the colony,

(A) Government paid for the passage of each person above ten years of age L. 8, 8s. and one shilling per day for victualling them.

Wales.

lony without material loſs was diſcovered. In that veſſel, out of 130 head which he embarked at Bombay, one cow only died on the paſſage, and that too on the day before his arrival.

The ſcarcity of cattle naturally raiſed their price. Even after this laſt importation, an Engliſh cow in calf ſold for L. 80.

Notwithſtanding the various obſtacles which induſtry had met in the cultivation of this ſettlement, it yet made conſiderable advances; for in October 1793, the value of land had ſo riſen that one ſettler ſold his allotment of 30 acres for as many pounds; and one farm, with the houſe, &c. ſold for L.100. The value of ground, indeed, was conſiderably enhanced by government agreeing to purchaſe the redundance of the produce of the ſettlers at fixed prices. Wheat properly dried and cleanſed was received from the ſettlers at Sydney, by the commiſſary, at 10s. per buſhel. Some cultivators, however, had deviſed another mode of diſpoſing of their corn. One of them, whoſe ſituation was near Parramatta, having obtained a ſmall ſtill from England, found it more advantageous to draw an ardent diabolical ſpirit from his wheat, than to ſend it to the ſtores. From one buſhel of wheat he obtained nearly five quarts of ſpirit, which he ſold or paid in exchange for labour, at the rate of five or ſix ſhillings per quart. A better uſe was made of grain by another ſettler; who having a mill, ground it, and procured 44lb. of good flour, from a buſhel of wheat taken at 59lb. This flour he ſold at 4d. per lb.

By a return of the number of perſons in New South Wales and Norfolk Iſland in April 1794, it appeared that there were in all 4414, including women and children; the annual expenſe of whom, to the mother-country, Mr Collins eſtimates at L.161,101. Rapid ſtrides, however, were at that time making towards independence, if not towards an ability of repaying to England a part of what the ſettlement had coſt her. Already the colony lived on grain of its own growth, and an increaſe of live ſtock was become almoſt certain. There were now 4665 acres of ground cleared for cultivation; more than half of which had been effected by thoſe who had become ſettlers in the courſe of fifteen months.

To this ſpirit of improvement ſuch a check was given in September 1794, that not more than a third of government ground, and a fifth of ground belonging to individuals, was in cultivation 1795. As this event has been miſrepreſented, we ſuſpect purpoſely, by ſome of our journaliſts, we ſhall give the true account of it in the words of Mr Collins himſelf.

"The Francis ſchooner (ſays he) returned from Norfolk, having been abſent about eight weeks and three days. From Mr King, who commanded in that iſland, we learned that his harveſt had been prodigiouſly productive. He had purchaſed from the firſt crops, which the ſettlers had brought to market, upwards of 11,000 buſhels of maize; and bills for the amount were drawn by him in favour of the reſpective ſettlers; but requiring the ſanction of the Lieutenant governor, they were now ſent to Port Jackſon. Mr King had been partly induced to make this proviſional kind of purchaſe under an idea, that the corn would be acceptable at Port Jackſon, and alſo in compliance with the conditions on which the ſettlers had received their reſpective allotments under the regulations of Governor Phillip; that is to ſay, that their overplus grain ſhould be purchaſed at a fair market-price. Being, however, well ſtocked with that article already, the Lieutenant governor did not think himſelf juſtifiable in putting the crown to ſo great an expenſe (nearly L. 3000 Sterling), and declined accepting the bills." This naturally excited ſome diſcontents in Norfolk Iſland, and one or two ſettlers gave up their farms; but immediately on the arrival of Governor Hunter, he paid for the corn, and tranquillity was reſtored to the iſland.

Though ſeveral quarrels had occurred between the natives and individuals among the coloniſts, yet it was ſuppoſed that our people were in general the aggreſſors. The governor had taken much pains to inſpire the natives with confidence, and had in a great meaſure ſucceeded. To theft they were naturally and irreſiſtibly inclined: but, like other ſavages, they ſeemed unconſcious of the crime, and were ſeldom deterred by detection from mixing with the coloniſts. At a ſettlement which had early been formed at a river called the *Hawkeſbury* (and at which, cultivation having gone on well, there was, in courſe, much grain to ſtimulate to depredation), the natives aſſumed a more formidable appearance.

"At that ſettlement (ſays Mr Collins) an open war ſeemed about this time to have commenced between the natives and the ſettlers; and word was received overland, that two people were killed by them; one a ſettler of the name of Wilſon, and the other a freeman, one William Thorp, who had hired himſelf to this Wilſon as a labourer. The natives appeared in large bodies, men, women, and children, provided with blankets and nets to carry off the corn, of which they appeared as fond as the natives who lived among us, and ſeemed determined to take it whenever and wherever they could meet with opportunities. In their attacks they conducted themſelves with much art; but where that failed they had recourſe to force; and on the leaſt appearance of reſiſtance made uſe of their ſpears or clubs. To check at once, if poſſible, theſe dangerous depredators, Captain Paterſon directed a party of the corps to be ſent from Paramatta, with inſtructions to deſtroy as many as they could meet with of the wood tribe (Bè-diagal); and, in the hope of ſtriking terror, to erect gibbets in different places, whereon the bodies of all they might kill were to be hung. It was reported that ſeveral of theſe people were killed in conſequence of this order; but none of their bodies being found (perhaps if any were killed they were carried off by their companions), the number could not be aſcertained. Some priſoners, however, were taken, and ſent to Sydney; one man (apparently a cripple), five women, and ſome children. One of the women, with a child at her breaſt, had been ſhot through the ſhoulder, and the ſame ſhot had wounded the babe. They were immediately placed in a hut near our hoſpital, and every care taken of them that humanity ſuggeſted. The man was ſaid, inſtead of being a cripple, to have been very active about the farms, and inſtrumental in ſome of the murders which had been committed. In a ſhort time he found means to eſcape, and by ſwimming reached the north ſhore in ſafety; whence, no doubt, he got back to his friends. Captain Paterſon hoped, by detaining the priſoners and treating them well, that ſome good effect might reſult; but

but finding, after some time, that coercion, not attention, was more likely to answer his ends, he sent the women back. While they were with us, the wounded child died, and one of the women was delivered of a boy, which died immediately. On our withdrawing the party, the natives attacked a farm nearly opposite Richmond Hill, belonging to one William Rowe, and put him and a very fine child to death; the wife, after receiving several wounds, crawled down the bank, and concealed herself among some reeds half immersed in the river, where she remained a considerable time without assistance: being at length found, this poor creature, after having seen her husband and her child slaughtered before her eyes, was brought into the hospital at Paramatta, where she recovered, though slowly, of her wounds."

By the vigorous measures which were adopted, the colony, towards the close of 1796, had acquired a degree of strength which seemed to ensure its future prosperity. Not only the necessary edifices were raised for the habitations of its people, but some for the purposes of religion, amusement, &c. A playhouse had been erected at the expense of some persons who performed in it for their own emolument, and who admitted auditors at one shilling each. A convenient church had been built, a printing-press had been set up, the civil court was open for the recovery of debts by action and for proving wills, licenses had been issued to regulate the sale of spirits, and passage-boats were established for the convenience of communication between the different settlements. In the houses of individuals were to be found most of the comforts, and not a few of the luxuries, of life; and, in a word, the former years of famine, toil, and difficulty, were now exchanged for those of plenty, ease, and pleasure.

The quantity of ground at this time in cultivation was 5419 acres; of which 2547 were occupied by settlers. The number of persons in New South Wales and its dependencies amounted to 4848. The price of labour, however, compared with the prices of provisions (as given in Mr Collins's Tables), does not appear so high as to enable the workman to live very comfortably. He who receives but three shillings for his day's work, and gives two shillings for a pound of mutton, fifteen pence for a pound of pork, and half of that sum for a pound of flour, will scarcely derive from his mere labour the support necessary for a family.

That many things are yet wanted to give full effect to the advantages which the colony now enjoys, Mr Collins declares in the following paragraph, with which he concludes his account:

"The want at this time of several public buildings in the settlement has already been mentioned. To this want must be added, as absolutely necessary to the well-being and comfort of the settlers, and the prosperity of the colony in general, that of a public store, to be opened on a plan, though not exactly the same, yet as liberal as that of the Island of St Helena, where the East India Company issue to their own servants European and Indian goods at 10 *per cent.* advance on the prime cost. Considering our immense distance from England, a greater advance would be necessary; and the settlers and others would be well satisfied, and think it equally liberal, to pay 50 *per cent.* on the prime cost of all goods brought from England; for at present they pay never less than 100, and frequently 1000, *per cent.* on what they have occasion to purchase. It may be supposed that government would not choose to open an account, and be concerned in the retail of goods, but any individual would find it to his interest to do this, particularly if assisted by government in the freight; and the inhabitants would gladly prefer the manufactures of their own country to the sweepings of the Indian bazars.

"The great want of men in the colony must be supplied as soon as a peace shall take place; but the want of respectable settlers may, perhaps, be longer felt; by these are meant men of property, with whom the gentlemen of the colony could associate, and who should be thoroughly experienced in the business of agriculture. Should such men ever arrive, the administration of justice might assume a less military appearance, and the trial by jury, ever dear and most congenial to Englishmen, be seen in New South Wales."

There is, however, one serious difficulty which the colony has not yet overcome, and which, until it be overcome, will certainly prevent such men from settling in New South Wales. Till some staple commodity can be raised for exportation, industrious free settlers will never be tempted to emigrate from Europe to a country where their industry cannot procure the comforts as well as the necessaries of life. The American colonies, in their infancy did not labour under this disadvantage. Tobacco soon became, and still continues to be, an article of such importance, that its cultivation afforded the trans-atlantic farmer a ready exchange for European commodities; whilst in New South Wales there seems to be no vegetable production of much value, except New Zealand hemp, which is produced indeed in great abundance in Norfolk Island: and which Captain Cook long ago pointed out as an article of great importance to the British navy. This is indeed a valuable plant, and grows in all the cliffs of the island, where nothing else will grow, in sufficient abundance to give constant employment to 500 people; yet when Mr Collins left the settlement, there was no more than one loom on the island, and the slay or reed was designed for coarse canvas; nor did they possess a single tool required by flax-dressers or weavers beyond the poor substitutes which they were obliged to fabricate for themselves. In this defect of necessaries for the manufacture, only 18 people could be employed in it; and of these the united labour in a week produced 16 yards of canvas, of the size called N° 7.

Besides a useful manufactory of this plant, which certainly might be established, the colony appears to possess several important advantages. From Mr Collins's narrative, it appears probable that a seal and perhaps a whale fishery might be established with a fair prospect of success; good rich earth is found near Sidney Cove; there are immense strata of coal in the southern part of New Holland; Norfolk Island abounds with lime; and vast quantities of shells, which answer the same purpose, have been found on the main land. Though the wood in general be not of a durable kind, it appears that there is some good timber near the Hawkesbury river; and at Norfolk Island and New Zealand it is remarkably fine.

WALES,

Wales, *New South*, a country of vast extent, but little known, lying round the southern part of Hudson's Bay.—*Morse.*

Wales, *New North*, an extensive territory of North-America; having Prince William's Land on the north, part of Baffin's Bay on the east, and separated from New South Wales, on the south by Seal river.—*ib.*

Wales, a plantation in Lincoln county, District of Maine, 55 miles north-east of Portland, and 180 from Boston. It contains 439 inhabitants.—*ib.*

WALHALDING, the Indian name of an eastern branch of Muskingum river, at the mouth of which stood Goschachguenk, a Delaware town, and settlement of Christian Indians.—*ib.*

WALLINGFORD, a township of Vermont, Rutland county, east of Tinmouth. It contains 536 inhabitants.—*ib.*

Wallingford, a pleasant post-town of Connecticut, New-Haven county, 13 miles S. W. of Middleton, 13 N. E. of New-Haven, and 195 north-east of Philadelphia. This township, called by the Indians *Coginchauge*, was settled in 1671; is divided into two parishes, and contains about 2000 inhabitants. It is 12 miles long, and 7 broad.—*ib.*

WALLKILL, a township of New York, Ulster county, on the creek of its name, about 15 miles N. by E. of Goshen, 11 west of Newburgh, and 58 N. W. of New York city. It contains 2571 inhabitants, of whom 340 are qualified electors, and 103 slaves.—*ib.*

WALNUT *Hills*, in the western territory of Georgia, are situated on a tract of land formed by Mississippi river and the Loosa Chitto, and on the north side of the latter.—*ib.*

WALLOOMSCHACK, a small branch of Hoosack river, Vermont.—*ib.*

WALLPACK, a township in Sussex county, New-Jersey, on Delaware river, about 11 miles west of Newtown, and 50 north-west of Brunswick. It contains 496 inhabitants, including 30 slaves.—*ib.*

WALPOLE (Horace, Earl of Orford), was the youngest son of the celebrated Sir Robert Walpole, afterwards Earl of Orford, by his first wife, Catharine, daughter of Robert Shorter, Esq; of Bybrook in Kent. He was born 1716; and was educated, first at Eton school, and afterwards at Cambridge. At Eton he formed an intimate aquaintance with the celebrated poet Gray; and they went together on the tour of Europe, in the years 1739, 1740, and 1741. Unhappily they had a dispute in the course of their travels, which produced a separation.

Mr Walpole was able to make a splendid figure during the remainder of his destined course; but poor Gray, after the separation, was obliged to observe a very severe economy. "This difference arose from the difference of their tempers: the latter being, from his earliest years, curious, pensive, and philosophical; the former, gay, lively, and inconsiderate. This, therefore, occasioned their separation at Reggio. Mr Gray went before him to Venice; and staying there till he could find means of returning to England, he made the best of his way home, repassing the Alps, and following almost the same rout, through France, which he had before gone to Italy. In justice to the memory of so respectable a friend, Mr Walpole (says Mr Mason, life of Gray, 4to, p. 4 .) enjoins me to charge him with the chief blame in their quarrel, confessing that more attention, complaisance, and deference, to a warm friendship, and superior judgment and prudence, might have prevented a rupture that gave much uneasiness to them both, and a lasting concern to the survivor; though in the year 1744 a reconciliation was effected between them, by a lady who wished well to both parties."—This event took place after their return to England; but the *wound* in their friendship left a *scar* that never was totally effaced.

We do not, indeed, think that Horace Walpole and Mr Gray were formed, either by nature or by habits, to continue long in a state of intimate friendship. Gray appears to have been a man of the purest moral principles, a friend to religion, pensive, and at least sufficiently conscious of his intellectual powers and intellectual attainments. Walpole's morality was certainly of a looser kind; he seems to have had no religion; he was often unseasonably gay; and to an equal share of intellectual pride, though without equal reason, he added the pride of birth. It can therefore excite no surprise that a man of Gray's independent spirit could not bear the supercilious freaks of such a character.

Mr Walpole was nominated to represent the city of Norwich, when his father visited it July 3d, 1733, having acquired consequence, not only as the son of the minister, but as having attended the Prince of Orange to England in that year. He was chosen member for Collington, in Cornwall, in the parliament which met June 25th, 1741; was a second time in parliament as representative for Castle Rising, in Norfolk, in 1747; and for King's Lynn in 1754 and 1761; and, at the expiration of that parliament, he finally retired from the stage of politics, and confined himself wholly to literary pursuits. He held to his death the office of usher of his Majesty's exchequer, controller of the pipe, and clerk of the estreats. Upon the death of his nephew George, third Earl of Orford, 1791, he succeeded to the title and estates; but that event made so little alteration in his mode of living, that we know not whether he ever took his seat in the house of peers. During almost the whole course of his life he was the victim of the gout, which at last reduced him to a cripple: but it never impaired his faculties; and, to the very moment of death, his understanding seemed to bid defiance to the shock of Nature. He died at his house in Berkesley Square, in 1796, having just entered his 80th year; and was interred in the family vault at Houghton, in a private manner, agreeably to his particular directions.

Horace, Lord Orford, was never married, and, by one of his biographers, his chief mistress through life is said to have been the muse. It is certain that he devoted the greater part of his life to belles lettres and virtú, though he ridiculously affected, in his letters to his friends, to despise learning and learned men, for which he was very properly reprimanded both by Gray and Hume. It was an affectation peculiarly absurd in him who was constantly publishing something, and who wrote with uncommon acrimony against all who presumed to call in question the fidelity of the picture which he had drawn of Richard III. or indeed to controvert any of his opinions. Hence his antipathy to Johnson, because he was a tory, a Christian, and a rigid moralist; whilst he himself was a whig, an infidel, and such a moralist as could

could retail, without bluſhing, all the ſcandalous anecdotes, whether true or falſe, of that auguſt family, from whom he acknowledged his whole fortune to be derived. He had, indeed, another reaſon for diſliking Johnſon. Lord Orford ſhone in converſation, and ſurpaſſed all his contemporaries in that kind of talk, which, without dazzling by its wit, always delighted; while Johnſon, when rouſed, knocked down, as by a flaſh of lightning, his Lordſhip and every one elſe who had the confidence before him to talk profanely. Johnſon's wit was original: Lord Orford's conſiſted of ludicrous ſtories and of literary and political anecdotes. His works, of which by far the moſt valuable part has long been in the hands of the public, were collected in 1798, and publiſhed in five volumes, 4to. They reſemble his converſation, being rather amuſing than profound or inſtructive.

Walpole, a poſt-town of New-Hampſhire, Cheſhire county, on the eaſtern ſide of Connecticut river, eleven miles ſouth of Charleſtown, 14 N. W. by N. of Keene, 108 weſt of Portſmouth, and 330 from Philadelphia. The townſhip contains 1245 inhabitants.—*Morse.*

Walpole, a townſhip of Maſſachuſetts, Norfolk county, on the great road to Providence, and 20 miles ſouth-weſt of Boſton. It was incorporated in 1724, and contains 1005 inhabitants.—*ib.*

WALSINGHAM, *Cape*, is on the eaſt ſide of Cumberland's Iſland, in Hudſon's Straits. N. lat. 62 39, W. long. 77 53. High water, at full and change, at 12 o'clock.—*ib.*

WALTHAM, a townſhip of Maſſachuſetts, Middleſex county, 11 miles north-weſt by north of Boſton. It was incorporated in 1737, and contains 882 inhabitants. —*ib.*

Waltham, or *Weſtham*, a village in Henrico county, Virginia, ſituated on the north ſide of James's river, 4 miles north-weſt of Richmond.—*ib.*

WAMPANOS, an Indian tribe, allies of the Hurons.—*ib.*

WANASPATUCKET *River*, riſes in Glouceſter, Rhode Iſland, and falls into Providence river a mile and an half north-weſt of Weyboſſet bridge. Upon this river formerly ſtood the only powder-mill in this ſtate, and within one mile of its mouth there are a ſlitting-mill, two paper-mills, two griſt-mills with four run of ſtones, an oil-mill, and a ſaw-mill.—*ib.*

WANDO, a ſhort, broad river of S. Carolina, which riſes in Charleſton diſtrict, and empties into Cooper's river, a few miles below Charleſton.—*ib.*

WANOOAETTE, an iſland in the S. Pacific Ocean, about two miles in extent from ſouth-eaſt to north-weſt. It is about 10 miles at north-weſt by weſt from the north end of Wateehoo Iſland.—*ib.*

WANTAGE, a townſhip near the N. W. corner of New-Jerſey, Suſſex county, 15 miles northerly of Newtown. It contains 1700 inhabitants, including 26 ſlaves.—*ib.*

WANTASTIC, the original name of Weſt river, Vermont.—*ib.*

WAPPACAMO *River*, a large ſouth branch of Patowmack river, which it joins in lat. 39 39 N. where the latter was formerly known by the name of Cohongoronto.—*ib.*

WAPUWAGAN *Iſlands*, on the Labrador coaſt, lie between lat. 50 and 50 5 N. and between long. 59 55 and 60 30 W.—*ib.*

WARD, a townſhip of Maſſachuſetts, Worceſter county, 5 miles ſouth of Worceſter, and 55 ſouth-weſt of Boſton, and contains 473 inhabitants.—*ib.*

WARDSBOROUGH, a townſhip of Vermont, Windham county, 12 or 15 miles weſt of Putney, and 27 north-eaſt of Bennington, and contains 753 inhabitants.—*ib.*

WARDSBRIDGE, a poſt-town of New York, Ulſter county, on the Wallkill, 10 miles north of Goſhen, 36 ſouth by weſt of Kingſton, and 156 north-eaſt by north of Philadelphia. It contains about 40 compact houſes and an academy.—*ib.*

WARE, a ſmall river of Maſſachuſetts which originates in a pond in Gerry, in Worceſter county, and in Peterſham it receives Swift river, and receiving Quaboag river, which comes from Brookfield, it thence aſſumes the name of Chicabee, and falls into Connecticut river at Springfield. Its courſe is ſouth and ſouth-weſt. —*ib.*

Ware, a townſhip of Maſſachuſetts, in Hampſhire county, incorporated in 1701, and contains 773 inhabitants. It is 15 miles N. E. of Springfield, and 70 miles weſt-north-weſt of Boſton.—*ib.*

WAREHAM, a townſhip of Maſſachuſetts, ſituated in Plymouth county, at the head of Buzzard's Bay, and on the weſt ſide, 60 miles S. by E. of Boſton. It was incorporated in 1739, and contains 854 inhabitants. N. lat. 41 45, W. long. 70 40.—*ib.*

WARING (Edward, M. D.), Lucaſian Profeſſor of Mathematics in the univerſity of Cambrige, was the ſon of a wealthy farmer, of the Old Heath, near Shrewſbury. The early part of his education he received at the free ſchool in Shrewſbury; whence he removed to Cambridge, and was admitted on the 24th of March 1753 a member of Magdalen College. Here his talents for abſtruſe calculation ſoon developed themſelves, and, at the time of taking his degree, he was conſidered as a prodigy in thoſe ſciences which make the ſubject of the bachelor's examination. The name of Senior Wrangler, on the firſt of the year, was thought ſcarcely a ſufficient honour to diſtinguiſh one who ſo far outſhone his contemporaries; and the merits of John Jebb were ſufficiently acknowledged, by being the ſecond in the liſt. Waring took his firſt, or bachelor's degree, in 1757, and the Lucaſian Profeſſorſhip became vacant before he was of ſufficient ſtanding for the next, or maſter's degree, which is a neceſſary qualification for that office. This defect was ſupplied by a royal mandate, through which he became maſter of arts in 1760; and ſhortly after his admiſſion to this degree, the Lucaſian Profeſſor.

The royal mandate is too frequently a ſcreen for indolence; and it is now become almoſt a cuſtom, that heads of colleges, who ought to ſet the example in diſcipline to others, are the chief violators of it, by making their office a pretext for taking their doctor's degree in divinity, without performing thoſe exerciſes which were deſigned as proofs of their qualifications. Such indolence cannot be imputed to Waring; yet ſeveral circumſtances, previous to his election into the profeſſorial chair, diſcovered that there was, at leaſt, one perſon in the univerſity who diſapproved of the anticipation of degrees by external influence.—Waring, before his election, gave a fmall fpecimen of his abilities, as proof of his qualification for the office which he was then foliciting; and a controverfy on his merits enfued: Dr Powell, the mafter of St John's college, attacking, in two pamphlets, the Profeffor; and his friend, afterwards Judge Wilfon, defending. The attack was fcarcely warranted by the errors in the fpecimen; and the abundant proofs of talents in the exercife of the profefforial office are the beft anfwers to the farcafms which the learned divine amufed himfelf in cafting on rifing merit. An office held by a Barrow, a Newton, a Whifton, a Cotes, and a Sanderfon, muft excite an ingenuous mind to the greateft exertions; and the new Profeffor, whatever may have been his fuccefs, did not fall behind any of his predeceffors, in either zeal for the fcience, or application of the powers of his mind, to extend its boundaries. In 1762, he publifhed his Mifcellanea Analytica; one of the moft abftrufe books written on the abftrufeft parts of algebra. This work extended his fame over all Europe. He was elected, without folicitation on his part, member of the focieties of Bononia and Gottingen; and received flattering marks of efteem from the moft eminent mathematicians at home and abroad. The difficulty of this work may be prefumed from the writer's own words, "I cannot fay that I know any one who thought it worth while to read through the whole, and perhaps not the half of it."

Mathematics did not, however, engrofs the whole of his attention. He could dedicate fome time to the ftudy of his future profeffion; and in 1767, he was admitted to the degree of doctor of phyfic; but, whether from the incapacity of uniting together the employments of active life with abftrufe fpeculation, or from the natural diffidence of his temper, for which he was moft peculiarly remarkable; the degree which gave him the right of exercifing his talents in medicine was to him merely a barren title. Indeed he was fo embarraffed in his manners before ftrangers, that he could not have made his way in a profeffion in which fo much is done by addrefs; and it was fortunate that the cafe of his circumftances permitted him to devote the whole of his time to his favourite purfuit. His life paffed on, marked out by difcoveries, chiefly in abftract fcience; and by the publication of them in the Philofophical Tranfactions, or in feparate volumes, under his own infpection. He lived fome years after taking his doctor's degree, at St Ives, in Huntingdonfhire. While at Cambridge he married—quitted Cambridge with a view of living at Shrewfbury; but the air or fmoke of the town being injurious to Mrs Waring's health, he removed to his own eftate at Plaifley, about 8 miles from Shrewfbury, where he died in 1797, univerfally efteemed for inflexible integrity, modefty, plainnefs, and fimplicity of manners. They who knew the greatnefs of his mind from his writings looked up to him with reverence everywhere: but he enjoyed himfelf in domeftic circles with thofe chiefly among whom his purfuits could not be the object either of admiration or envy. The outward pomp which is affected frequently in the higher departments in academic life, was no gratification to one whofe habits were of a very oppofite nature; and he was too much occupied in fcience to attend to the intrigues of the univerfity. There, in all queftions of fcience, his word was the law; and at the annual examination of the candidates for the prize inftituted by Dr Smith, he appeared to the greateft advantage. The candidates were generally three or four of the beft proficients in the mathematics at the previous annual examination for the bachelor's degree, who were employed from nine o'clock in the morning to ten at night, with the exception of two hours for dinner, and twenty minutes for tea, in anfwering, *viva voce*, or writing down anfwers to the profeffor's queftions, from the firft rudiments of philofophy to the deepeft parts of his own and Sir Ifaac Newton's works. Perhaps no part of Europe affords an inftance of fo fevere a procefs; and there was never any ground for fufpecting the Profeffor of partiality. The zeal and judgment with which he performed this part of his office cannot be obliterated from the memory of thofe who paffed through his fiery ordeal.

Wifhing to do ample juftice to the talents and virtue of the Profeffor, we feel ourfelves fomewhat at a lofs in fpeaking of the writings by which alone he will be known to pofterity. He is the difcoverer, according to his own account, of nearly 400 propofitions in the analytics. This may appear a vain-glorious boaft, efpecially as the greater part of thofe difcoveries are likely to fink into oblivion; but he was, in a manner, compelled to make it by the infolence of Lalande, who, in his life of Condorcet, afferts that, in 1764, there was no firft-rate analyft in England. In reply to this affertion, the Profeffor, in a letter to Dr Mafkelyne, firft mentions, with proper refpect, the inventions and writings of Harriot, Briggs, Napier, Wallis, Halley, Bruncker, Wren, Pell, Barrow, Mercator, Newton, De Moivre, Maclaurin, Cotes, Stirling, Taylor, Simpfon, Emerfon, Landen, and others; of whom Emerfon and Landen were living in 1764. He then gives a fair and full detail of his own inventions, of which many were publifhed anterior to 1764; and concludes his letter in thefe words.

"I know that Mr Lalande is a firft-rate aftronomer, and writer of aftronomy; but I never heard that he was much converfant in the deeper parts of mathematics; for which reafon I take the liberty to afk him the following queftions:

"Has he ever read or underftood the writings of the Englifh mathematicians: and, as the queftion comes from me, I fubjoin, particularly of mine? If the anfwer be in the negative, as it is my opinion, if his anfwer be the truth, that it will, then there is an end of all further controverfy;—but if he afferts that he has, which is more than Condorcet did by his own acknowledgment, then he may know, from the enumeration of inventions made in the prefaces, with fome fubfequent ones added, that they are faid to amount to more than 400 of one kind or other. Let him try to reduce thofe to as low a number as he can, with the leaft appearance of candour and truth; and then let him compare the number with the number of inventions of any French mathematician or mathematicians, either in the prefent or paft times, and there will refult a comparifon (if I miftake not) not much to his liking; and, further, let him compare fome of the firft inventions of the French mathematicians with fome of the firft contained in my works, both as to utility, generality, novelty, difficulty, and elegance, but wifely as to utility, there is little contained in the deep parts of any fcience; he will find their difficulty

difficulty and novelty from his difficulty of underftanding them, and his never having read any thing fimilar before; their generality, by the application of them; principles of elegance will differ in different perfons.— I muft fay, that he will probably not find the difference expected. After or before this inquiry is inftituted for mine, let him perform the fame for the other Englifh mathematicians; and when he has completed fuch inquiries, and not before, he will become a judge of the juftice of his affertion; but I am afraid that he is not a fufficient adept in thefe ftudies to inftitute fuch inquiries; and if he was, fuch inquiries are invidious, troublefome, and of fmall utility."

By mathematical readers this account, which was not publifhed by the Profeffor himfelf, is allowed to be very little, if at all, exaggerated. Yet if, according to his own confeffion, "few thought it worth their while to read even half of his works," there muft be fome grounds for this neglect, either from the difficulty of the fubject, the unimportance of the difcoveries, or a defect in the communication of them to the public. The fubjects are certainly of a difficult nature, the calculations are abftrufe; yet Europe contained many perfons not to be deterred by the moft intricate theorems. Shall we fay then, that the difcoveries were unimportant? If this were really the cafe, the want of utility would be a very fmall difparagement among thofe who cultivate fcience with a view chiefly to entertainment and the exercife of their rational powers. We are compelled, then, to attribute much of this neglect to a perplexity in ftyle, manner, and language; the reader is ftopped at every inftant, firft to make out the writer's meaning, then to fill up the chafm in the demonftration. He muft invent anew every invention; for, after the enunciation of the theorem or problem, and the mention of a few fteps, little affiftance is derived from the Profeffor's powers of explanation. Indeed, an anonymous writer, certainly of very confiderable abilities, has aptly compared the works of Waring to the heavy appendages of a Gothic building, which add little of either beauty or ftability to the ftructure.

A great part of the difcoveries relate to an affumption in algebra, that equations may be generated by multiplying together others of inferior dimenfions. The roots of thefe latter equations are frequently terms called *negative* or *impoffible*; and the relation of thefe terms to the coefficients of the principal equation is a great object of inquiry. In this art the profeffor was very fuccefsful, though little affiftance is to be derived from his writings in looking for the real roots. We fhall not, perhaps, be deemed to depreciate his merits, if we place the feries for the fum of the powers of the roots of any equation among the moft ingenious of his difcoveries; yet we cannot add, that it has very ufefully enlarged the bounds of fcience, or that the algebraift will ever find occafion to introduce it into practice. We may fay the fame on many ingenious transformations of equations, on the difcovery of impoffible roots, and fimilar exertions of undoubtedly great talents. They have carried the affumption to its utmoft limits; and the difficulty attending the fpeculation has rendered perfons more anxious to afcertain its real utility; yet they who reject it may occafionally receive ufeful hints from the Mifcellanea Analytica.

The firft time of Waring's appearing in public as an author was, we believe, in the latter end of the year 1759, when he publifhed the firft chapter of the Mifcellanea Analytica, as a fpecimen of his qualifications for the profefforfhip; and this chapter he defended, in a reply to a pamphlet, intitled, "Obfervations on the Firft Chapter of a book called Mifcellanea Analytica." Here the Profeffor was ftrangely puzzled with the common paradox, that nothing divided by nothing may be equal to various finite quantities, and has recourfe to unqueftionable authorities in proof of this pofition. The names of Maclaurin, Sanderfon, De Moivre, Bernoulli, Monmort, are ranged in favour of his opinion: But Dr Powell was not fo eafily convinced, and returns to the charge in defence of the Obfervations; to which the Profeffor replied in a letter to the Rev. Dr Powell, Fellow of St John's college, Cambridge, in anfwer to his Obfervations, &c. In this controverfy, it is certain that the Profeffor gave evident proofs of his abilities; though it is equally certain that he followed too implicitly the decifions of his predeceffors. No apparent advantage, no authority whatever, fhould induce mathematicians to fwerve from the principles of right reafoning, on which their fcience is fuppofed to be peculiarly founded. According to Maclaurin, Dr Waring, and others, If $P=\frac{a-x}{a^2-x^2}$, then, when $x=a$, P is equal to $\frac{1}{2a}$; for, fay they, $\frac{a-x}{a^2-x^2}$ is equal to $\frac{a-x}{a-x}\times\frac{1}{a+x}$; that is, when x is equal to a, $P=\frac{1}{a+x}$, or $\frac{1}{2a}$. But when x is equal to a, the numerator and denominator of the fraction $\frac{a-x}{a^2-x^2}$ are both, in their language, equal to nothing. Therefore, nothing divided by nothing is equal to $\frac{1}{2a}$. In the fame manner, $\frac{a-x}{a^3-x^3}=\frac{1}{a^2+ax+x^2}\times\frac{a-x}{a-x}$, which, when x is equal to a, becomes $\frac{1}{3a^2}$. Therefore, nothing divided by nothing is equal to $\frac{1}{3a^2}$, or $\frac{1}{3a^2}=\frac{1}{2a}$; that is, $\frac{1}{3a}=\frac{1}{2}$; which is abfurd. But we need only trace back our fteps to fee the fallacy in this mode of reafoning. For P is equal to fome number multiplied into $\frac{a-x}{a-x}$; that is, when x is equal to a, P is equal to fome number multiplied into nothing, and divided by nothing; that is, P is, in that cafe, no number at all. For $a-a$ cannot be divided by $a-x$ when x is equal to a, fince, in that cafe, $a-x$ is no number at all.

If, in the beginning of his career, the Profeffor could admit fuch paralogifms into his fpeculations, and the writings of the mathematicians, for nearly a century before him, may plead in his excufe, we are not to be furprifed that his difcoveries fhould be built rather on the affumptions of others than on any new principles of his own. Acquiefcing in the ftrange notion, that nothing could be divided by nothing, and produce a variety of numbers, he as eafily adopted the pofition, that an equation has as many roots as it has dimenfions.—

Thus

Waring.

Thus 2 and — 4 are said to be roots of the equation $x^2 - 2x = 8$, though 4 can be the root only of the equation; $x^2 - 2x = 8$, which differs so materially from the preceding, that in one case $2x$ is added, in the other case it is subtracted from x^2.

Allowances being made for this error in the principles, the deductions are, in general, legitimately made; and any one, who can give himself the trouble of demonstrating the propositions, may find sufficient employment in the Professor's analytics. Perhaps it will be sufficient for a student to devote his time to the simplest case $x^n \pm 1 = 0$; and when he has found a few thousand roots of + 1 and — 1, the publication of them may afford to posterity a strong proof of the ingenuity of their predecessors, and the application of the powers of their mind to useful and important truths. In this exercise may be consulted the method given by the Professor, of finding a quantity, which, multiplied into a given irrational quantity, will produce a rational product, or consequently exterminate irrational quantities out of a given equation; but if an irrational quantity cannot come into an equation, the utility of this invention will not be admitted without hesitation.

The "Proprietates Algebraicarum Curvarum," published in 1772, necessarily labour under the same defects with the Miscellanea Analytica, the Meditationes Algebraicæ, published in 1770, and the Meditationes Analyticæ, which were in the press during the years 1773, 1774, 1775, 1776. These were the chief and the most laborious works edited by the Professor; and in the Philosophical Transactions is to be found a variety of papers, which alone would be sufficient to place him in the first rank in the mathematical world. The nature of them may be seen from the following catalogue.

Vol. LIII. p. 294, Mathematical Problems.—LIV. 193. New Properties in Conics.—LV. 143. Two Theorems in Mathematics.—LXIX. Problems concerning Interpolations.—86. A General Resolution of Algebraical Equations.—LXXVI. 81. On Infinite Series. LXXVII. 71. On Finding the Values of Algebraical Quantities by Converging Serieses, and Demonstrating and Extending Propositions given by Pappus and others.—LXXVIII. 67. On Centripetal Forces.—*Ib.* 588. On some Properties of the Sum of the Division of Numbers.—LXXIX. 166. On the Method of Correspondent Values, &c.—*Ib.* 185. On the Resolution of Attractive Powers.—LXXXI. 146. On Infinite Serieses.—LXXXIV. 385—415. On the Summation of those Serieses whose general term is a determinate function of z, the distance of the term of the Series.

For these papers, the Professor was, in 1784, deservedly honoured by the Royal Society with Sir Godfrey Copley's medal; and most of them afford very strong proofs of the powers of his mind, both in abstract science, and the application of it to philosophy; though they labour, in common with his other works, under the disadvantage of being clothed in a very unattractive form. The mathematician, who has resolution to go through them, will not only add much to his own knowledge, but be usefully employed in dilating on those articles for the benefit of the more general reader. We might add in this place, a work written on morals and metaphysics in the English language; but as a few copies only were presented to his friends, and it was the Professor's wish that they should not have a more extensive circulation, we shall not here enlarge upon its contents.

In the mathematical world, the life of Waring may be considered as a distinguished æra. The strictness of demonstration required by the ancients had gradually fallen into disuse, and a more commodious, though almost mechanical mode by algebra and fluxions took its place, and was carried to the utmost limit by the Professor. Hence many new demonstrations may be attributed to him, but 400 discoveries can scarcely fall to the lot of a human being. If we examine thoroughly those which our Professor would distinguish by such names, we shall find many to be mere deductions, others, as in the solution of biquadratics, anticipated by former writers. But if we cannot allow to him the merit of so inventive a genius, we must applaud his assiduity; and distinguished as he was in the scientific world, the purity of his life, the simplicity of his manners, and the zeal which he always manifested for the truths of the Gospel, will intitle him to the respect of all who do not esteem the good qualities of the heart inferior to those of the head.

WARMINSTER, a small post-town of Virginia, situated on the north side of James' river, in Amherst county, about 90 miles above Richmond. It contains about 40 houses, and a tobacco warehouse. It is 332 miles from Philadelphia, 21 miles from Charlottesville, and 9 from Newmarket. There is also a township of this name in Buck's county, Pennsylvania.—*Morse.*

WARM *Spring*, a ridge of mountains bears this name, a part of the Alleghany Mountains, situated N. W. of the Calf Pasture, and famous for warm springs. The most efficacious of these, are two springs in Augusta, near the sources of James' river, where it is called Jackson's river. They rise near the foot of the ridge of mountains, generally called the Warm Spring Mountains, but in the maps Jackson's Mountains. The one is distinguished by the name of the Warm Spring, and the other of the Hot Spring. The Warm Spring issues with a very bold stream, sufficient to work a grist-mill, and to keep the waters of its bason, which is 30 feet in diameter, at the vital warmth, viz. 96° of Farenheit's thermometer. The matter with which these waters is allied is very volatile; its smell indicates it to be sulphureous, as also does the circumstance of turning silver black. They relieve rheumatisms. Other complaints also of very different natures have been removed or lessened by them. It rains here 4 or 5 days in every week. The Hot Spring is about six miles from the Warm, is much smaller, and has been so hot as to have boiled an egg. Some believe its degree of heat to be lessened. It raises the mercury in Farenheit's thermometer to 112 degrees, which is fever heat. It sometimes relieves where the Warm Spring fails. A fountain of common water, issuing within a few inches of its margin, gives it a singular appearance. Comparing the temperature of these with that of the hot springs of Kamschatka, of which Krachininnikow gives an account, the difference is very great, the latter raising the mercury to 200 degrees, which is within 12 degrees of boiling water. These springs are very much resorted to, in spite of a total want of accommodation for the sick. Their waters are strongest in the hottest months, which occasions their being visited in July and August principally.

principally. The Sweet Springs, in the county of Botetourt, at the eastern foot of the Alleghany, are about 42 miles from the Warm Springs.—*ib.*

WARNER, a township of New Hampshire, Hillsborough county. It was incorporated in 1774, and contains 863 inhabitants.—*ib.*

WARREN, a new county of the Upper District of Georgia.—*ib.*

WARREN, a county of Halifax district, N. Carolina. It contains 9,397 inhabitants, including 4,720 slaves. —*ib.*

WARRENTON, a post-town, and the capital of the above-mentioned county, situated 16 miles E. by N. of Hillsborough, 35 west of Halifax, 54 north of Raleigh, 83 south of Petersburg in Virginia, and 390 from Philadelphia. The town contains about 30 houses, and stands in a lofty, dry, and healthy situation. Europeans, of various nations, reside in and about the town. Here is a respectable academy, having generally from 60 to 70 students.—*ib.*

WARREN, a township of Vermont, Addison county, about 30 miles N. E. by E. of Crown Point.—*ib.*

WARREN, a post-town of the District of Maine, Lincoln county, adjoining Camden and Thomaston; 33 miles south by west of Belfast, 203 N. E. by N. of Boston, and 557 from Philadelphia. This township is separated from that of Thomaston, by St George's river; was incorporated in 1776, and contains 642 inhabitants.—*ib.*

WARREN, a township of Grafton county, New-Hampshire, north-east of Orford, adjoining, incorporated in 1763, and contains 206 inhabitants.—*ib.*

WARREN, a post-town of Rhode-Island, in Bristol county, pleasantly situated on Warren river and the north-east part of Narraganset Bay, 4 miles north of Bristol, 10 S. S. E. of Providence, and 302 from Philadelphia. This is a flourishing town; carries on a brisk coasting and West-India trade, and is remarkable for ship building. The whole township contains 1122 inhabitants, of whom 22 are slaves. Rhode-Island College was first instituted in this town, and afterwards removed to Providence.—*ib.*

WARREN, a new township of Herkemer county, New-York. It was taken from German Flats, and incorporated in 1796.—*ib.*

WARREN, a part of the township of Chenengo, in the State of New-York, on Susquehannah river, bears this name in De Witt's map.—*ib.*

WARREN, a township in Connecticut, in Litchfield county, between the townships of Kent and Litchfield. —*ib.*

WARREN, a post town of Virginia, 10 miles from Warminster, 21 from Charlottesville, and 326 from Philadelphia.—*ib.*

WARREN's *Point*, on the coast of Nova-Scotia, is on the east side of Chebucto Harbour, about 2 miles east of the town of Halifax. It is at the entrance of a creek, which receives Saw-Mill river and other streams. —*ib.*

WARRINGTON, the name of two townships of Pennsylvania; the one in York county, the other in Buck's county.—*ib.*

WARSAW, or *Wassaw*, an island and sound on the coast of Georgia, between the mouth of Savannah river and that of Ogeechee. The island forms the north side of Ossabaw Sound; being in a N. E. direction from Ossabaw Island. Warsaw Sound is formed by the northern end of the island of its name, and the southern end of Tybee Island.—*ib.*

WARTON (Joseph, D. D.) was born either towards the end of the year 1721, or in the beginning of the year 1722. He was the eldest son of Thomas Warton, B. D. who had been fellow of Magdalen College, Oxford; poetry professor from the year 1718 to 1728, and vicar of Basingstoke in Hampshire, and of Cobham in Surrey. Where the subject of this memoir was born we have not learned, though, were we to hazard a conjecture, we would say that it was in Oxford, as his father probably resided in that city during his professorship.

Our knowledge of the private history of Dr Warton is indeed extremely limited. We do not even know at what school, or in what college, he was educated; though it was probably at Winchester school, and certainly in some of the colleges in the university of Oxford. For many years he was successively under and upper master of Winchester college; but resigned the last of these offices when he found the infirmities of age coming upon him; and was succeeded by Dr Goddard the present excellent master. He was likewise prebendary of the cathedral church of Winchester, and rector of Wickham in Hampshire, where he died, aged 78.

His publications are few, but valuable. A small collection of poems, without a name, was the first of them, and contained the Ode to Fancy, which has been so much and so deservedly admired. They were all of them afterwards printed in Dodsley's collection. He was also a considerable contributer to the Adventurer, published by Dr Hawkesworth; and all the papers which contain criticisms on Shakespeare were written by him and his brother Thomas Warton, the subject of the next article.

The first volume of his Essay on the Life and Writings of Pope was published, had passed through several editions, and an interval of between 20 and 30 years had elapsed, before he gave a second volume of that elegant and instructive work to the world. He had not only meditated, but had collected materials for a literary history of the age of Leo X: and proposals were actually in circulation for a work of that kind; but it is probable that the duties of his station did not leave him the necessary leisure for an undertaking which required years of seclusion and independence. His last and late work which he undertook for the booksellers at a very advanced age, was an edition of Pope's Works, that has not altogether satisfied the public expectation. He retained, with great propriety indeed, many of the notes of Warburton: but is severely reprehended by the author of the Pursuits of Literature for suppressing the name of that prelate on his title-page, or including it only, as subordinate to his own, in the general expression *others*.

Dr Warton was cheerful in his temper, convivial in his disposition, of an elegant taste and lively imagination, with a large portion of scholarship, and a very general knowledge of the Belles Lettres of Europe; it may be presumed that Dr Warton possessed, beyond most men, the power of enlivening Classical Society. He was the intimate friend of Dr Johnson; was seen at the

Warton.

parties of Mrs Montague, as well as at the table of Sir Joshua Reynolds, and was an original member of the Literary Club. He possessed a liberal mind, a generous disposition, and a benevolent heart. He was not only admired for his talents and his knowledge, but was beloved for those qualities which are the best gifts of this imperfect state.

Warton (Thomas), the brother of the preceding, was born in the year 1728. He received, as we have reason to believe, the first part of his education at Winchester; and at the age of 16 was entered a commoner of Trinity College, Oxford, under the tuition of Mr Geering.

Biog. Dict.

He began his poetical career at an early age. In 1745, he published five pastoral eclogues, in which are beautifully described the miseries of war to which the shepherds of Germany were exposed. Not long after, in the year 1748, he had full scope afforded for the exertion of his genius. It is well known that Jacobite principles were suspected to prevail in the university of Oxford about the time of the rebellion in the year 1745. Soon after its suppression, the drunkenness and folly of some young men gave offence to the court, in consequence of which a prosecution was instituted in the court of King's Bench, and a stigma was fixed on the vice-chancellor and some other heads of colleges in Oxford. Whilst this affair was the general subject of conversation, Mr Mason published his "Isis," an elegy, in which he adverts to the above-mentioned circumstances. In answer to this poem, Mr Warton, encouraged by Dr Huddesford, the president of the college, published, in 1749, "The Triumph of Isis," which excelled more in manly expostulation and dignity than the poem that produced it did in neatness and elegance. With great poetical warmth, and a judicious selection of circumstances, he characterises the eminent men who had been educated in Oxford, and draws a striking and animated portrait of Dr King, the celebrated public orator of that time. The whole poem shews the early maturity of his genius, and is finished with happy diligence.

In the year 1751, he succeeded to a fellowship of his college, and was thus placed in a situation easy and independent, and particularly congenial with his habits of retirement and study. In 1753, appeared his observations on "The Faery Queen of Spencer," in 8vo, a work which he corrected, enlarged, and republished, in two volumes crown octavo, in the year 1762. He sent a copy of the first edition to Dr Johnson, who, in a letter to him upon the subject, expressed this handsome compliment: "I now pay you a very honest acknowledgement for the advancement of the literature of our native country: you have shewn to all, who shall hereafter attempt the study of ancient authors, the way to success, by directing them to the perusal of the books which these authors had read."

In 1754, Dr Johnson visited Oxford for the first time after he had quitted residence there. Much of his time was spent with Mr Warton; and there appeared to have been a considerable degree of confidential intercourse between them upon literary subjects, and particularly on their own works. A pleasing account of this visit was communicated by Mr Warton to Mr Boswell, who has inserted it in his life of Johnson.

In 1755, Mr Warton exerted himself to procure for his friend the degree of master of arts by diploma from the university of Oxford; an honour which Johnson esteemed of great importance to grace the title page of his dictionary which he was about to publish. In 1756, Mr Warton was elected professor of poetry, which office he held for the usual term of ten years. His lectures were remarkable for elegance of diction and justness of observation. One of them on the subject of pastoral poetry, was afterwards prefixed to his edition of Theocritus. In 1758, he contributed to assist Dr Johnson in the subscription to his edition of Shakespeare, and furnished him with some valuable notes. The Doctor remarks in a letter to him, when soliciting his farther aid, "It will be reputable to my work, and suitable to your professorship, to have something of yours in my notes."

From the Clarendon press, in the year 1766, he published "Anthologiæ Græcæ, a Constantino Cephalâ conditæ, Libri tres," in 2 vols, 12mo. He concludes the learned and classical preface to this work, which is replete with accurate remarks on the Greek epigram, in the following words, which mark this publication for his own: Vereor ut hactenus in plexendis florum corollis otium nimis longum protraxerim. Proximè sequetur, cui nunc omnes operas et vires intendo, Theocritus. Interea quasi promulsidem convivii Lectoribus meis elegantias hasce vetustatis eruditæ propino."

In the year 1770, he conferred a similar honour upon the academical press by his edition of Theocritus, in 2 vols, 8vo. He undertook this work by the advice of Judge Blackstone, then fellow of All-Souls College, and an ardent promoter of every publication that was likely to do credit to the Clarendon press. This elaborate publication reflects no small credit on the learning, diligence, and taste of the editor.

In 1771, he was elected a fellow of the Antiquarian Society, and was presented by the Earl of Lichfield to the small living of Kiddington in Oxfordshire, which he held till his death. He likewise in this year published an improved account of "The Life of Sir Thomas Pope, founder of Trinity College, Oxford. In composing these memoirs, he bestowed much labour and research, and shewed great judgment in the arrangement of his materials. But possibly, in his ardour to pay a debt of gratitude, he has not sufficiently considered what was due to his own fame. The same strength of description and vigour of remark would have better suited the life of some eminently distinguished character, and extended the reputation of the author as a biographer beyond the circle of those academical readers who are influenced by the same feelings of veneration, respect, and gratitude which prompted Mr Warton to compose this work. The preface contains some excellent remarks on biographical writing.

The plan for a history of English poetry was laid by Pope, enlarged by Gray: but to bring an original plan nearly to a completion was reserved for the perseverance of Warton. In 1774 appeared his first volume; in 1778, the second and third; which brings the narrative down to the commencement of the reign of Elizabeth in 1581. This work displays the most singular combination of extraordinary talents and attainments. It unites the deep and minute researches of the antiquary with the elegance of the classical scholar and the skill of

Warton. of the practiſed writer. The ſtyle is vigorous and manly; the obſervations acute and juſt; and the views of the ſubject are extenſive and accurate.

In 1777, he collected his poems into an octavo volume, containing miſcellaneous pieces, odes, and ſonnets. This publication may be conſidered in ſome meaſure original; there being only ſeven pieces that had before appeared, and near three times that number which were then printed for the firſt time.

In vindication of the opinion he had given in his ſecond volume of "The Hiſtory of Poetry," relative to the ingenious attempt of Chatterton to impoſe upon the public, he produced, in 1782, "An Inquiry into the Authenticity of the Poems attributed to Rowley." In this excellent pamphlet the principles of true criticiſm are laid down, an appeal is properly made to the internal evidence of the poems; and upon theſe grounds it is proved, in the moſt ſatisfactory manner, that they could not have been written by a monk of the fourteenth century.

The year 1785 brought him thoſe diſtinctions which were no leſs honourable to thoſe who conferred than to him who received them. He was appointed poet-laureat on the death of Whitehead, and elected Camden profeſſor of ancient hiſtory on the reſignation of Dr Scott. His inauguration lecture was delivered in a clear and impreſſive manner from the profeſſorial chair. It contained excellent obſervations of the Latin hiſtorians, and was written in a ſtrong, perſpicuous, and claſſical ſtyle. In his odes, the vigour and brilliancy of his fancy were not proſtituted to an inſipid train of courtly compliments: each preſents an elegant ſpecimen of deſcriptive poetry, and as all of them have only a ſlight relation to the particular occaſion on which they were written, and have always a view to ſome particular and intereſting ſubject, they will be peruſed with pleaſure as long as this ſpecies of compoſition is admired.

He made occaſional journeys to London to attend the literary club, of which he was ſome years a member; and to viſit his friends, particularly Sir Joſhua Reynolds. At his houſe he was ſure to meet perſons remarkable for faſhion, elegance, and taſte.

His laſt publication, except his official odes, conſiſted of Milton's ſmaller poems. A quarto edition appeared in 1790, with corrections and additions. The great object of theſe notes is to explain the alluſions of Milton, to trace his imitations, and to illuſtrate his beauties.

Until he reached his ſixty-ſecond year, he continued to enjoy vigorous and uninterrupted health. On being ſeized with the gout, he went to Bath, and flattered himſelf, on his return to college, that he was in a fair way of recovery. But the change that had taken place in his conſtitution was viſible to his friends. On Thurſday, May 20, 1790, he paſſed the evening in the common room, and was for ſome time more cheerful than uſual. Between ten and eleven o'clock he was ſtruck with the palſy, and continued inſenſible till his death, which happened the next day at two o'clock. On the 27th, his remains were interred in the college chapel with the moſt diſtinguiſhed academical honours. The inſcription upon the flat ſtone which is placed over his grave contains only an enumeration of his preferments.

Such was the general conduct and behaviour of Mr Warton as to render him truly amiable and reſpectable. By his friends he was beloved for his open and eaſy manners; and by the members of the univerſity at large he was reſpected for his conſtant reſidence, ſtrong attachment to Alma Mater, his ſtudious purſuits, and high literary character. In all parties where the company accorded with his inclination, his converſation was eaſy and gay, enlivened with humour, enriched with anecdote, and pointed with wit. Among his peculiarities it may be mentioned that he was fond of all military ſights. He was averſe to ſtrangers, particularly to thoſe of a literary turn; and yet he took a great pleaſure in encouraging the efforts of riſing genius, and aſſiſting the ſtudious with his advice; as many of the young men of his college, who ſhared his affability and honoured his talents, could teſtify. He was bred in the ſchool of punſters; and made as many good ones as Barton and Leigh, the celebrated word-hunters of his day. Under the maſk of indolence, no man was more buſy; his mind was ever on the wing in ſearch of ſome literary prey. Although, at the accuſtomed hours of Oxford ſtudy, he was often ſeen ſauntering about, and converſing with any friend he chanced to meet; yet, when others were waſting their mornings in ſleep, he was indulging his meditations in his favourite walks, and courting the Muſes. His ſituation in Oxford was perfectly congenial with his diſpoſition, whether he indulged his ſallies of pleaſantry in the common room, retired to his own ſtudy, or to the Bodleian library; ſauntered on the banks of his favourite Cherwell, or ſurveyed, with the enthuſiaſtic eye of taſte, the ancient gateway of Magdalen College, and other ſpecimens of Gothic architecture.

The following is a liſt of Mr Warton's works; 1. "Five Paſtoral Eclogues," 4to, 1745. Reprinted in Peach's Collection of Poems. 2. "The Pleaſures of Melancholy," written in 1745; firſt printed in Dodſley's Collection, and afterwards in the Collection of Mr Warton's Poems. 3. "Progreſs of Diſcontent," written in 1746. Firſt printed in the "Student," a periodical paper. 4. "The Triumph of Iſis, a Poem," 4to, 1750. 5. "Newmarket, a Satire," folio, 1751. 6. "Ode for Muſic," performed at the theatre in Oxford 1751. 7. "Obſervations on the Faerie Queen of Spencer," 8vo, 1754. 8. "Inſcriptionum Metricarum Delectus," 4to, 1758. 9. "A Deſcription of the City, College and Cathedral, of Wincheſter," 8vo, no date. 10. "The Life of Sir Thomas Pope," in the 5th volume of the Biographia Britannica," republiſhed in 1772. 11. "The Life and Literary Remains of Ralph Bathurſt, M. D Dean of Wells, and Preſident of Trinity College in Oxford," 1761. 12. "A Companion to the Guide, and a Guide to the Companion," 12mo, 1762. 13. "The Oxford Sauſage," in which are ſeveral Poems by Warton. 14. "Anthologiæ Græcæ a Conſtantino Cephalâ conditæ Libri tres," 2 tom. 1766. 15. "Theocritis Syracuſii quæ ſuperſunt, cum Scholiis Græcis," &c. 2 tom. 4to, 1770. 16. "Hiſtory of Engliſh Poetry, from the Cloſe of the 11th to the Commencement of the 18th Century," 4to, Vol. I. 1774. Vol. II. 1778. Vol. III 1781. 17. "Poems," 8vo, 1777. 18. "Specimen of a Hiſtory of Oxfordſhire," 1783. 19 "An Enquiry into the Authenticity of the Poems attributed to Thomas Rowley," 8vo, 1782. 20. "Verſes on Sir J.

Reynolds's

Reynolds's painted Window in New College Chapel, 4to," 1782. 21. "Poems on several Occasions, by John Milton, with Notes critical and explanatory," 8vo, 1785.

WARWICK, a county of Virginia, bounded north by York county, and south by James' river, which separates it from Isle of Wight, and Nansemond counties. It is the oldest county of the State, having been established in 1628. It contains 1690 inhabitants, of whom 990 are slaves.—*Morse.*

WARWICK, a township of Massachusetts, in Hampshire county, incorporated in 1763, and contains 1246 inhabitants. It is bounded north by the state of New-Hampshire, not far east of Connecticut river, and is 90 miles north west of Boston.—*ib.*

WARWICK, the chief town of Kent county, Rhode-Island, situated at the head of Narraganset Bay, and on the west side; about 8 miles south of Providence. The township contains 2,493 inhabitants, including 35 slaves. A cotton manufactory has been established in this town upon an extensive scale. One of Arkwright's machines was erected here in August, 1795; and the yarn produced answers the most sanguine expectation. This town was the birth-place of the celebrated Gen. Green. —*ib.*

WARWICK, a township of New-York, Orange county, bounded easterly by New-Cornwall, and southerly by the State of New-Jersey. It contains 3,603 inhabitants; of whom 383 are electors, and 95 slaves.—*ib.*

WARWICK, the name of two townships of Pennsylvania; the one in Buck's county, the other in that of Lancaster. In the latter is the fine Moravian settlement called Litiz.—*ib.*

WARWICK, a post-town of Maryland, Cecil county, on the eastern shore of Chesapeak Bay; about 14 miles southerly of Elkton, 8 N. E. of Georgetown Cross Roads, and 57 south-west of Philadelphia.—*ib.*

WARWICK, a small town of Chesterfield county, Virginia; agreeably situated on the south-west side of James' river, about 7 miles south-south east of Richmond, and 17 north of Petersburg. Vessels of 250 tons burden can come to this town. In 1781, Benedict Arnold destroyed many vessels in the river and on the stocks at this place.—*ib.*

WASHINGTON (George), one of those few men who have been great without being criminal, was born on the 11th of *February*, 1732 *in the Parish of Washington, Virginia.* He was descended from an ancient family in Cheshire, of which a branch had been established in Virginia about the middle of the last century. We are not acquainted with any remarkable circumstances of his education or his early youth; and we should not indeed expect any marks of that disorderly prematureness of talent, which is so often fallacious, in a character whose distinguishing praise was to be perfectly regular and natural. His classical instruction was probably small, such as the private tutor of a Virginian country gentleman could at that period have imparted; and if his opportunities of information had been more favourable, the time was too short to profit by them. Before he was twenty he was appointed a major in the colonial militia, and he had very early occasion to display those political and military talents, of which the exertions on a greater theatre have since made his name so famous throughout the world.

The plenipotentiaries who framed the treaty of *Aix la Chapelle*, by leaving the boundaries of the British and French territories in North America unfixed, had sown the seeds of a new war, at the moment when they concluded a peace.—The limits of Canada and Louisiana, negligently described in vague language by the treaties of Utrecht and Aix la Chapelle, because the greater part of these vast countries was then an impenetrable wilderness, furnished a motive or a pretext, for one of the most successful but one of the most bloody and wasteful wars in which Great Britain had ever been engaged.

In the disputes which arose between the French and English officers on this subject, Major Washington was employed by the governor of Virginia, in a negotiation with the French governor of *Fort du Quesne* (now Pittsburgh); who threatened the English frontiers with a body of French and their Indian allies. He succeeded in averting the invasion; but hostilities becoming inevitable, he was in the next year appointed lieutenant colonel of a regiment raised by the colony for its own defence; to the command of which he soon after succeeded. The expedition of Braddock followed in the year 1755; of which the fatal issue is too well known to require being described by us. Colonel Washington served in that expedition only as a volunteer; but such was the general confidence in his talents, that he may be said to have conducted the retreat. Several British officers are still alive who remember the calmness and intrepidity which he shewed in that difficult situation, and the voluntary obedience which was so cheerfully paid by the whole army to his superior mind. After having acted a distinguished part in a subsequent and more successful expedition to the Ohio, he was obliged by ill health, in the year 1758, to resign his military situation. The sixteen years which followed of the life of Washington, supply few materials for the biographer. Having married Mrs Custis, a Virginian lady of amiable character and respectable connections, he settled at his beautiful seat of Mount Vernon, of which we have had so many descriptions; where, with the exception of such attendance as was required by his duties as a magistrate and a member of the assembly, his time was occupied by his domestic enjoyments, and the cultivation of his estate, in a manner well suited to the tranquillity of his pure and unambitious mind. At the end of this period he was called by the voice of his country from this state of calm and secure though unostentatious happiness.

The events of that deplorable contest which rent asunder the British empire, are yet perhaps too recent for free and impartial discussion. The connection between Great Britain and America had long been suffered to remain in that uncertain state which is not inconsistent with mutual harmony as long as each party reposes confidence in each other. The supreme authority of the mother country was respected without being definitely acknowledged in its utmost extent. It was not systematically declared, nor rigorously enforced by England—It was not zealously watched nor legally limited by the colonies. England derived increased wealth and prosperity from the growing greatness of America. America was protected by the strength of England, and felt pride in the participation of her liberty. In this happy state of mutual affection, neither party

party harboured such distrust as to prompt them to take security for the authority of one or the privileges of the other. All those doubtful and dangerous questions which relate to the boundaries of power and freedom were forgotten, during this fortunate connection between obedient liberty and protecting authority. The parliament of Great Britain, content with that stream of wealth which *indirectly* flowed into the Exchequer through the channels of American commerce, had hitherto either doubted their right to tax America, or wisely forborn to exercise that unprofitable and perilous right. The scheme of an American revenue had been suggested to Sir Robert Walpole, but that cautious and pacific minister declared, " that he would leave it to bolder men."—Men bolder, but not wiser, than Sir Robert were at length found to adopt it. The counsels which predominated at the beginning of the present reign were favourable to such plans. A system of taxing America by the British parliament was avowed and acted upon.—A stamp duty was imposed on all the colonies. Whatever may have been the causes of this unfortunate deviation from the sound principles of the ancient American policy, the effects soon became manifest. The old affectionate confidence of the colonists was changed into hostile distrust; instead of relying in the benevolence of a paternal government, they began to think of guarding themselves against an enemy. The intercourse of jealous chicane succeeded to that of generous friendship; metaphysical discussions with respect to the limits and foundation of supreme power, which seldom disturb the quiet of a happy and well governed people, were for the first time forced on the attention of the Americans by the indiscretion of their governors. Nothing, however, is more certain, than that the first views of the American leaders were merely *defensive*; and that they were far advanced in the resistance before the idea of independence presented itself to their minds. They did not seek separation; it was obtruded on them by the irresistible force of circumstances. After they had appealed to arms, it was extremely obvious, that their power must be tottering as long as they acknowledged the lawfulness of the power against whom they were armed; that the zeal of their partizans never could be vigorous till they had cut off all possibility of retreat; and that no foreign state would be connected with them, as long as they themselves confessed, that they had neither the right nor the power to enter into a legitimate and permanent alliance. All the passions, which in violent times are almost sure to banish moderate counsels, were at work in America. These consequences always follow in the necessary course of things, from the first impulse that throw a people into confusion: most certainly these consequences did not enter into the original plan of the American leaders. There are those who remember the horror expressed by Dr Franklin, before he left England, at the bare mention of separation: yet Franklin was, perhaps, of all the Americans, the man most likely to entertain such a project. Their leaders were in general men of great sobriety, caution, and practical good sense; zealous indeed for the maintenance of their ancient legal rights and privileges; but utterly untainted by that daring and speculative character which leads men to seek untried, and perilous paths in politics, for their own greatness or for supposed public benefit.

The disorders in America had reached their height, and it became perfectly obvious, that the dispute between the two countries could only be decided by arms, when the representatives of the thirteen provinces assembled at Philadelphia, on the 26th of October, 1774. Of this famous assembly Mr Washington was one; no American united in so high a degree as he did military experience, with respectable character and great natural influence. He was therefore appointed to the command of the army which assembled in the New England Provinces, to hold in check the British army under General Gage, then encamped at Boston. If these circumstances had not called Washington forth, he would have lived happy, and died obscure, as a respectable country gentleman in Virginia: now the scene opened which made his name immortal: so dependent upon accident is human fame, and so great is the power of circumstances in calling forth, and perhaps even in forming, the genius of men.

In the month of July, 1775, General Washington took the command of the continental army before Boston. To detail his conduct in the years which followed, would be to relate the history of the American war: a most memorable and instructive part of British annals, which has not yet been treated in a manner suited to its importance and dignity. Within a very short period after the declaration of independence, the affairs of America were in a condition so desperate, that perhaps nothing but the *peculiar* character of Washington's genius could have retrieved them. Activity was the policy of invaders. In the field of battle the superiority of a disciplined army is displayed. But delay was the wisdom of a country defended by undisciplined soldiers against an enemy who must be more exhausted by time than he could be weakened by defeat. It required the consummate prudence, the calm wisdom, the inflexible firmness, the moderate and well balanced temper of Washington to embrace such a plan of policy, and to persevere in it; to resist the temptations of enterprize; to fix the confidence of his soldiers without the attraction of victory; to support the spirit of the army and the people amidst those slow and cautious plans of defensive warfare which are more dispiriting than defeat itself; to contain his own ambition and the impetuosity of his troops; to endure temporary obscurity for the salvation of his country, and for the attainment of solid and immortal glory, and to suffer even temporary reproach and obloquy, supported by the approbation of his own conscience and the applause of that small number of wise men whose praise is an earnest of the admiration and gratitude of posterity. Victorious generals easily acquire the confidence of their army. Theirs, however, is a confidence in the *fortune* of their general. That of Washington's army was a confidence in his *wisdom*. Victory gives spirit to cowards, and even the agitations of defeat sometimes impart a courage of despair. Courage is inspired by success, and it may be stimulated to desperate exertion even by calamity, but it is generally palsied by inactivity—A system of cautious defence is the severest trial of human fortitude. By this test the firmness of Washington was tried. His intrepidity never could have

Washington.

have maintained itſelf under ſuch circumſtances, if it had ariſen from ambition or vain glory, from robuſt nerves or diſorderly enthuſiaſm. It ſtood the teſt, becauſe it grew out of the deep root of principle and duty. His mind was ſo perfectly framed, that he did not need the vulgar incentives of fame and glory to rouſe his genius. In him public virtue was a principle of ſufficient force to excite the ſame great exertions to which the rabble of heroes muſt be ſtimulated by the love of power or of praiſe.

It is hardly neceſſary to ſay, that the courage which flowed from honeſty, was tempered in its exerciſe by humanity. The character of Waſhington was not deformed by any of thoſe furious paſſions which drive men to ferocity. His military life was unſtained by military cruelty; and if we lamented the ſeverity of ſome of his acts, we never were at liberty to queſtion their juſtice. It would be unjuſt to aſcribe the mildneſs of the American war excluſively to the perſonal character of Waſhington.—It muſt be imputed in a great meaſure to the ſobriety and moderation of the national temper. Never was a civil war ſo ſpotleſs as that which unhappily broke out between the two nations of the Engliſh race. Not a ſingle maſſacre, not a ſingle aſſaſſination, no ſlaughter in cold blood tarniſhed the glory of conqueſt or aggravated the ſhame of defeat. Gallantry and humanity characterized this conteſt between two nations who amidſt all the fierceneſs of hoſtility ſhewed themſelves worthy of each other's friendſhip.

We are well aware that the military critics of Europe, accuſtomed to the vaſt and ſcientific plans, to the complicated yet exact movements, to the daring and ſplendid exploits of great European generals, may conſider the moſt deciſive ſucceſs in a war like the American as a very inadequate title to the name and glory of an illuſtrious commander. We feel all the deference which upon every ſubject is due from the ignorant to the maſters of the art. But we doubt the ſoundneſs of the judgment of military critics on this ſubject. To us it ſeems probable that more genius and judgment are generally exerted by uneducated generals and among irregular armies, than in the conteſts of thoſe commanders who are more perfectly inſtructed in military ſcience. It is with the arts of war as with every other art. Wherever any art is moſt perfected, there is leaſt room for the exertions of individual genius. Where moſt can be done by rule, leaſt is left for talents. We accordingly find that thoſe ſurprizes and ſtratagems which are ſo brilliant and intereſting a part of the hiſtory of war in paſt times, are now infinitely more rare, becauſe vigilance is now more uniform and the means of defence more perfect. It is now much more eaſy than it was formerly to calculate the event of a campaign from the numbers of the contending armies, the fortreſſes which they poſſeſs and the nature of the country which they occupy. It is impoſſible that the art of war ſhould ever be ſo improved, as to obliterate all differences between the talents of generals: but it is certain that its improvement has a tendency to make the inequality of their talents leſs felt. It cannot be denied that they who beſt know the power of the *art* are the moſt ſober *admirers* of the talents of generals. But whatever be the juſtneſs of theſe obſervations, it muſt be univerſally allowed, that as much judgment and intrepidity may be ſhewn among irregular and imperfectly diſciplined armies as under the moſt highly improved ſyſtem of mechanical tactics. This is ſufficient for our purpoſe; for we are now contemplating the character of him whoſe leaſt praiſe is that of being a great commander, whoſe valour was the miniſter of virtue, and whoſe military genius is chiefly ennobled by being employed in the defence of juſtice.

It is extremely remarkable, that though there never was a civil conteſt diſgraced by ſo few violent or even ambiguous acts as the American war, yet ſo pure were the moral ſentiments of Waſhington, that he could not look back on the period of hoſtilities with unmixed pleaſure. An Italian nobleman, who viſited him after the peace, had often attempted, in vain, to turn the converſation to the events of the war. At length he thought he had found a favourable opportunity of effecting his purpoſe; they were riding together over the ſcene of an action where Waſhington's conduct had been the ſubject of no ſmall animadverſion. Count ——— ſaid to him, "Your conduct, Sir, in this action has been criticized." Waſhington made no anſwer, but clapped ſpurs to his horſe; after they had paſſed the field, he turned to the Italian and ſaid, "Count ———, I obſerve that you wiſh me to ſpeak of the war. It is a converſation which I always avoid. I rejoice at the eſtabliſhment of the liberties of America. But the time of the ſtruggle was a horrible period, in which the beſt men were compelled to do many things repugnant to their nature."

So fatal are even the mildeſt civil commotions to men's morals, and ſo admirable was the temperament of the man who had too much magnanimity not to take up arms at the call of his country, and yet too delicate a purity to dwell with complacency on the recollection of ſcenes which, though they were the ſource of his glory, allowed more ſcope for the diſplay of his talents than for the exerciſe of his humanity!

The concluſion of the American war permitted Waſhington to return to thoſe domeſtic ſcenes, from which nothing but a ſenſe of duty ſeems to have had the power to draw him. But he was not allowed long to enjoy this privacy. The ſupreme government of the United States, haſtily thrown up, in a moment of turbulence and danger, as a temporary fortification againſt anarchy, proved utterly unadequate to the preſervation of general tranquillity and permanent ſecurity. The confuſions of civil war had given a taint to the morality of the people which rendered the reſtraints of a juſt and vigorous government more indiſpenſably neceſſary. Confiſcation and paper money, the two greateſt ſchools of rapacity and diſhoneſty in the world, had widely ſpread their poiſon among the Americans. In this ſtate of things, which threatened the diſſolution of morality and government, good men ſaw the neceſſity of concentrating and invigorating the ſupreme authority. Under the influence of this conviction, a convention of delegates was aſſembled at Philadelphia, which ſtrengthened the bands of the Federal Union, and beſtowed on Congreſs thoſe powers which were neceſſary for the purpoſes of good government. Waſhington was the preſident of this convention, and afterwards was unanimouſly elected preſident of the United States of America, under what was called "The New Conſtitution," though it might have been called a *reform* of the republican government, as that republican government itſelf was only a *reform* of of the ancient colonial conſtitution under the Britiſh crown. None of theſe changes extended ſo far as an attempt to new-model the whole ſocial and political ſyſtem.

There is nothing more ſtriking in the whole character of General Waſhington, and which diſtinguiſhes him more from other extraordinary men, than the circumſtances which attended his promotion and retreat from office. Unſought elevation and cheerful retreat are almoſt peculiar to him. He eagerly courted privacy, and only *ſubmitted* to exerciſe authority as a public duty. The promotions of many men are the triumph of ambition over virtue. The promotions, even of good men, have generally been eagerly ſought by them from motives which were very much mixed. The promotions of Waſhington alone, ſeem to have been victories gained by his conſcience over his taſte. His public virtue did not need the ambiguous aid of ambition to urge its activity. We do not affirm that all ambition is to be condemned; it is perhaps neceſſary to ſtimulate the ſluggiſhneſs of human virtue. Thoſe who avoid the public ſervice from an epicurean love of pleaſure and of eaſe, from the fear of danger, from inſenſibility to honeſt fame, are not ſo much to be praiſed for their exemption from ambition as to be deſpiſed for baſer vices. But though it be mean to be *below* ambition, it is a proof of unſpeakable greatneſs of mind to be *above* it. This elevation the mind of Waſhington had reached; and unleſs we are greatly deceived, he will be found to be a ſolitary example of ſuch exalted magnanimity. To deſpiſe what all other men purſue; to ſhew himſelf equal to the higheſt places without ever ſeeking any; and to be as active and intrepid from public virtue alone, as others are under the influence of the moſt reſtleſs ambition; theſe are the noble peculiarities of the character of Waſhington.

Events occurred during his chief magiſtracy, which convulſed the whole political world, and which tried moſt ſeverely his moderation and prudence. The French revolution took place.

Both friends and enemies have agreed in ſtating that Waſhington, from the beginning of that revolution, had no great confidence in its beneficial operation. He muſt indeed have deſired the abolition of deſpotiſm, but he is not to be called the enemy of liberty if he dreaded the ſubſtitution of a more oppreſſive deſpotiſm. It is extremely probable that his wary and practical underſtanding, inſtructed by the experience of popular commotions, augured little good from the daring ſpeculations of inexperienced viſionaries. The progreſs of the revolution was not adapted to cure his diſtruſt, and when, in the year 1793, France, then groaning under the moſt intolerable and hideous tyranny, became engaged in war with almoſt all the governments of the civilized world, it is ſaid to have been a matter of deliberation with the Preſident of the United States, whether the republican envoy, or the agent of the French princes ſhould be received in America as the diplomatic repreſentative of France. But whatever might be his private feelings of repugnance and horror, his public conduct was influenced only by his public duties. As a virtuous man he muſt have abhorred the ſyſtem of crimes which was eſtabliſhed in France. But as the firſt magiſtrate of the American Commonwealth, he was bound only to conſider how far the intereſt and ſafety of the people whom he governed, were affected by the conduct of France. He ſaw that it was wiſe and neceſſary for America to preſerve a good underſtanding and a beneficial intercourſe with that great country, in whatever manner ſhe was governed, as long as ſhe abſtained from committing injury againſt the United States. Guided by this juſt and ſimple principle, uninfluenced by the abhorrence of crimes which he felt and which others affected, he received Mr Genet, the miniſter of the French Republic. The hiſtory of the outrages which that miniſter committed, or inſtigated, or countenanced againſt the American government, muſt be freſh in the memory of all our readers. The conduct of Waſhington was a model of firm and dignified moderation. Inſults were offered to his authority in official papers, in anonymous libels, by incendiary declaimers, and by tumultuous meetings. The law of nations was trampled under foot. His confidential miniſters were ſeduced to betray him, and the deluded populace were ſo inflamed by the arts of their enemies that they broke out into inſurrection. No vexation, however galling, could diſturb the tranquillity of his mind, or make him deviate from the policy which his ſituation preſcribed. With a more confirmed authority, and at the head of a longer eſtabliſhed government, he might perhaps have thought greater vigour juſtifiable. But in his circumſtances he was ſenſible that the nerves of authority were not ſtrong enough to bear being ſtrained. Perſuaſion, always the moſt deſirable inſtrument of government, was in his caſe the ſafeſt. Yet he never overpaſſed the line which ſeparates conceſſion from meanneſs. He reached the utmoſt limits of moderation, without being betrayed into puſillanimity. He preſerved external and internal peace by a ſyſtem of mildneſs, without any of thoſe virtual confeſſions of weakneſs, which ſo much diſhonour and enfeeble ſupreme authority. During the whole of that arduous ſtruggle, his perſonal character gave that ſtrength to a *new magiſtracy*, which in other countries ariſes from ancient habits of obedience and reſpect. The authority of his virtue was more efficacious for the preſervation of America than the legal powers of his office.

During the turbulent period of the French revolution, Waſhington was re-elected to the office of the Preſidency of the United States, which he held from April 1789, till September 1796. Probably no magiſtrate of any commonwealth, ancient or modern, ever occupied a place ſo painful and perilous. Certainly no man was ever called upon ſo often to ſacrifice his virtuous feelings (he had no other ſacrifices to make) to his public duty. Two circumſtances of this ſort deſerve to be particularly noticed. In the ſpring of 1794, he ſent an embaſſador to Paris with credentials, addreſſed to his "Dear friends the citizens compoſing the Committee of Public Safety of the French Republic," whom he prays God "to take under his holy protection." Fortunately the American embaſſador was ſpared the humiliation of preſenting his credentials to theſe bloody tyrants. Their power was ſubverted, and a few of them had ſuffered the puniſhment of their crimes, which no puniſhment could expiate, before his arrival at Paris. The dignity of the nature of man was not ſo degraded, as that the embaſſador of the moſt reſpectable republic in the world ſhould be preſented to

Washington.

ruffians and affaffins, who had the incredible effrontery to call their tyranny by the profaned name of republic. But hiftorians who relate heroic facrifices of feeling to duty, when they tell us, that Brutus thought himfelf obliged to condemn his fon to death, will not forget to add, that Wafhington was compelled to call Roberfpierre "his friend!" In the contemplation of fuch fcenes good men for a moment forget their deliberate opinions, and are led to curfe civil government itfelf with all the fevere duties which it impofes, and all the cruel facrifices which it demands.

Another ftruggle of feeling and duty Wafhington had to encounter, when he was compelled to fuppress the infurrection in the weftern counties of Pennfylvania by force of arms. But here he had a confolation. The exercife of mercy confoled his mind for the neceffity of having recourfe to arms. Never was there a revolt quelled with fo little blood. Scarcely ever was the bafeft daftard fo tender of his own life, as this virtuous man was of the lives of his fellow citizens. The value of his clemency is enhanced by recollecting, that he was neither without provocations to feverity, nor without pretexts for it. His character and his office had been reviled in a manner almoft unexampled among civilized nations.—His authority had been infulted.—His fafety had been threatened. Of his perfonal and political enemies fome might, perhaps, have been fufpected of having inftigated the infurrection; a greater number were thought to wifh well to it; and very few fhewed much zeal to fupprefs it. *Is habitus animorum fuit, ut peffimum facinus auderent pauci, plures vellent, omnes paterentur.* But neither refentment, nor fear, nor even policy itfelf, could extinguifh the humanity of Wafhington. This feems to have been the only facrifice which he was incapable of making to the intereft of his country.

Throughout the whole courfe of his fecond prefidency, the danger of America was great and imminent almoft beyond example. The fpirit of change indeed, at that period, fhook all nations. But in other countries, it had to encounter ancient and folidly eftablifhed power. It had to tear up by the roots long habits of attachment in fome nations for their government, of awe in others, of acquiefcence and fubmiffion in all. But in America the government was new and weak. The people had fcarce time to recover from the ideas and feelings of a recent civil war. In other countries the volcanic force muft be of power to blow up the mountains, and to convulfe the continents that held it down, before it could efcape from the deep caverns in which it was imprifoned:—in America it was covered only by the afhes of a late convulfion, or at moft by a little thin foil, the produce of a few years quiet.

To thefe difficulties were added others, which, if duly weighed, will perhaps difpofe us to confider the prefervation of America from confufion under the government of Wafhington, by means fo mild, and apparently fo inadequate, as either one of the greateft mafter pieces of civil prudence that ever diftinguifhed an adminiftration, or one of the moft fortunate accidents that ever befel a ftate. To thofe who may reprefent it as mere good fortune, we may anfwer with FONTENELLE, who, when fomebody congratulated him on the *good fortune* of his friend *Lamotte*, in the fuccefs of his tragedy of "Inez de Caftro," anfwered—"*Oui; mais c'eft une* FORTUNE *qui n'arrive jamais aux fots.*"—The names of liberty and republic were fo naturally and juftly dear to the Americans, that, far from its being difficult to range them under any banners on which thefe words were infcribed, it was very far indeed from being eafy to perfuade them, that fuch founds could reprefent any thing but juftice, benevolence, and happinefs. The government of America had none of thofe prejudices to employ, which in every other country were ufed with fuccefs to enflame the people againft the French revolution. They had, on the contrary, to contend with the prejudices of their people in the moft moderate precautions againft internal confufion, in the moft meafured and guarded refiftance to the unparalleled infults and enormous encroachments of France. Without zealous fupport from the people, the American government was impotent. It required a confiderable time, and it coft an arduous and dubious ftruggle, to direct the popular fpirit againft a fifter republic, eftablifhed among a people to whofe aid the Americans afcribed the eftablifhment of their independence. It is probable indeed, that no policy could have produced this effect, unlefs it had been powerfully aided by the crimes of the French government, which have proved the ftrongeft allies of all eftablifhed governments; which have produced fuch a general difpofition to fubmit to any *known* tyranny, rather than rufh into all the unknown and undefinable evils of civil confufion, with the horrible train of new and monftrous *tyrannies* of which it is ufually the forerunner. But with what juftice foever fome governments may be accufed of having engrafted fervility on the rational and generous horror of their fubjects againft the atrocities of the French revolution, moft certain it is, that the adminiftration of Wafhington cannot be charged with having fo perverted fuch a juft and noble fentiment. He employed it for the moft honeft and praifeworthy purpofes; to preferve the internal quiet of his country; to affert the dignity, and to maintain the rights of the commonwealth which he governed, againft foreign enemies. He avoided war without incurring the imputation of pufillanimity. He cherifhed the deteftation of Americans for anarchy, without weakening the fpirit of liberty; and he maintained, and even confolidated, the authority of government, without abridging the privileges of the people.

Among the many examples of change and viciffitude in political connexion, which are amufing from their fingularity, and which would be moft ufeful if they were received as leffons of moderation by contending parties; there is none, perhaps, more remarkable, than that which may be obferved in the life of General Wafhington. In 1776, he was confidered in England as a profcribed rebel. In 1796, he was regarded as the leader of the Englifh party in America. In 1776, his deftruction was thought the only means of preferving America to Great Britain. In 1796, his authority was thought the principal fecurity againft her falling under the yoke of France. In 1776, he looked to the aid of France, as his only hope of guarding the liberties of America againft England. In 1796, he muft have confidered the power of Great Britain as one main barrier of the fafety of America againft France. Never, perhaps, did twenty years in the life of any individual, produce fo ftriking and fo important a change. But there was no inconfiftency in his character. There was no change in his *principles* or *objects*. There was a great

great change of *circumſtances* which required a correſpondent variety in the *means* to be employed for the attainment of his objects, in the aid to be ſought, the connexions to be cultivated, the meaſures to be adopted for giving effect to his principles. Means, plans, and connections, muſt always vary with the infinite variety in the ſituations of men and of ſtates. But the principles of public virtue, which were the principles of Waſhington, are immortal and unchangeable. A good man always deſires the liberty and happineſs of his country, and, as far as poſſible, of the whole human race. But a wiſe man varies his means according to the changing circumſtances of the world, to ſecure the attainment of the ſame end. There would be no more real conſiſtency in the oppoſite conduct, that if a man were to continue the ſame precautions againſt being froſt-bitten at Bencoolen, which he had found neceſſary in Greenland; or employ the ſame anxious care to ſave himſelf from a *coup de ſoleil* in Canada, which might have been very prudent in Bengal.

The reſignation of Waſhington in 1796, is one of thoſe meaſures of his life in which his patriotiſm and prudence ſeem the moſt eminently conſpicuous. Nothing was more certain than his re-election, if he had thought it wiſe to offer himſelf as a candidate. In that unſettled ſtate of public affairs, it might at firſt ſight appear, that the man of moſt influence and weight in America ought to have remained at the helm. The conduct which he purſued was, certainly, however the moſt wiſe. All the enemies, and many of the friends, of the American government believed, that it had a ſevere trial to encounter, when the aid of Waſhington's character ſhould be withdrawn from its executive government. Many apprehended, that it had ſcarce vigour enough to ſurvive the experiment. And, if the trial had been delayed till the death of Waſhington, the event might perhaps have been more doubtful. It was neceſſary, that ſo critical an experiment ſhould be performed under his eye. It was fit that the Americans ſhould have an example of a quiet election and a proſperous adminiſtration, apparently independent of the perſonal influence of the great founder of their liberty, though, in reality, ſupported by the whole ſtrength of his character. It was fit, that the world ſhould ſee that the American government *was able to move by itſelf*; but it was alſo fit, that ſo hazardous a trial ſhould be made while that guardian wiſdom was at hand, which could guide and help its movements. The election of the firſt ſucceſſor of Waſhington was the moſt critical event in the hiſtory of the infant republic, and the example was likely to be of great and laſting importance. America and her friends, after the happy iſſue of this trial, may with confidence expect, that a government which has ſtood ſuch a teſt, will maintain itſelf againſt all future ſhocks; and that a people with ſuch an example before them, will ſo exerciſe their great and hazardous right of electing a firſt magiſtrate, as to preſerve the quiet of their country and the protecting power of the laws. In that caſe their fortune will be the more admirable, becauſe we have no authority from the experience of paſt times to expect ſuch a degree of prudence, moderation, and equanimity in any great community, as to make it ſafe for themſelves to be entruſted with that magnificent, but dangerous and generally fatal, privilege. If theſe happy conſequences enſue, America will have as much reaſon to be grateful to Waſhington for the ſeaſonable reſignation of his authority, as for its wiſe and honeſt exertions.

When he reſigned his preſidency, he publiſhed a valedictory addreſs to his countrymen, as he had before done when he quitted the command of the army in 1783. In theſe compoſitions, the whole heart and ſoul of Waſhington are laid open. Other ſtate-papers have, perhaps, ſhewn more ſpirit and dignity, more eloquence, greater force of genius, and a more enlarged comprehenſion of mind. But none ever diſplayed more ſimplicity and ingenuouſneſs, more moderation and ſobriety, more good ſenſe, more prudence, more honeſty, more earneſt affection for his country and for mankind, more profound reverence for virtue and religion; more ardent wiſhes for the happineſs of his fellow creatures, and more juſt and rational views of the means which alone can effectually promote that happineſs. It is difficult for any human compoſition to ſhew more clearly a well-diſciplined underſtanding and a pure heart.

From his reſignation till the month of July 1798, he lived in retirement at Mount Vernon. At this latter period, it became neceſſary for the United States to arm. They had endured with a patience, of which there is no example in the hiſtory of ſtates, all the contumely and wrong which ſucceſſive adminiſtrations in France had heaped upon them. Their ſhips were every where captured, their miniſters were detained in a ſort of impriſonment at Paris; while incendiaries, clothed in the ſacred character of embaſſadors, ſcattered over their peaceful provinces the fire-brands of ſedition and civil war. An offer was made to terminate this long courſe of injuſtice, for a bribe to the French miniſters.—This offer was made by perſons who *appeared* to be in the confidence of M. Talleyrand, who *profeſſed* to act by his authority; who have been ſince, indeed, diſavowed by him; but who never will be believed not to have been his agents, till he convicts them of impoſture by legal evidence, and procures them to be puniſhed for ſo abominable a fraud.

The United States reſolved to arm by land and ſea. The command of the army was beſtowed on General Waſhington; which he accepted, becauſe he was convinced, that "every thing we hold dear and ſacred was ſeriouſly threatened;" though he had flattered himſelf, "that he had quitted for ever the boundleſs field of public action, inceſſant trouble and high reſponſibility, in which he had long acted ſo conſpicuous a part." In this office he continued during the ſhort period of his life which ſtill remained.—On Thurſday the 12th December 1799, he was ſeized with an inflammation in his throat, which became conſiderably worſe the next day; and of which, notwithſtanding the efforts of his phyſicians, he died on Saturday the 14th of December 1799, in the 68th year of his age, and in the 23d year of the independence of the United States, of which he may be conſidered as the founder. The ſame calmneſs, ſimplicity and regularity, which had uniformly marked his demeanor, did not forſake him in his dying moments. He ſaw the approaches of death without fear:—he met them without parade.—Even the perfectly well-ordered ſtate of the moſt minute particulars of his private buſineſs, bore the ſtamp of that conſtant authority of prudence and practical reaſon over his actions, which was a diſtinguiſhing feature of his character. He died with

Washington. those sentiments of piety, which had given vigour and consistency to his virtue, and adorned every part of his blameless and illustrious life.

His will, which has been published since his death, is, like all his compositions, characteristic of his mind. It has been very well observed by a writer of genius, in a Daily Paper, that those dispositions of the will which regard the future emancipation of the slaves are peculiarly deserving of attention. A commentary on that part of the will would, perhaps, be the best system of rules for rational reform, that has ever been given to the world. The generous and just determination to emancipate the slaves, combined with the sacred regard for law in its harshest regulations, and property in its most odious form; the tender and provident solicitude for the emancipated slaves themselves, for the education of the young, and the support of the infirm; every thing in short indicates that union of benevolence and prudence which constitutes the true character of a REFORMER, and which distinguishes him from those restless and fierce disturbers of the world, who usurp the name of Reformers, and bring lasting discredit on the cause of reformation. The reforms of which Washington has furnished so beautiful a model in miniature, are those in which the heart is warm, and the head cool; in which the Reformer not only earnestly desires to do good, but deeply considers the best manner of doing it; in which he pursues his generous end with ardour, but examines with the utmost caution and deliberation the most effectual and the safest means of attaining it; in which he takes a large view of all the relations and tendencies of the change which he is about to introduce, of all its direct and indirect consequences; and guards his reform by every security that human prudence can devise, against any possibility of injury, either from the act or the example, to the rights or the happiness of any human being.

But to return from this digression: it is sufficient to say, that these dispositions of Washington's will bear the mark of his pure, temperate, and sedate character, which was not only free from the gross vices of sordid avarice and selfish ambition, but from the more refined and better disguised, though equally pernicious, vices of inordinate zeal even for good, of a violent passion for glory; in which there was nothing disorderly, nothing precipitate, nothing excessive, nothing ostentatious, of which usefulness was the object, and good sense the guide, and of which the grandeur arises only from the magnitude of the benefits which he conferred on his country. His character is surrounded with no glare.—There is little in it to dazzle. It has nothing to gratify those, who relish only that irregular and monstrous greatness, which fascinates the vulgar of all ranks and in all times. But those whose moral taste is more pure, will always admire in George Washington the nearest approach to uniform propriety, and perfect blamelessness, which has ever been attained by man, or which is perhaps compatible with the condition of humanity.

This imperfect sketch is necessarily defective in those interesting details of private life, which are the most important, as well as the most delightful part, of biography; but these defects will soon be amply supplied by the publication of the life of General Washington, which is now ready for the press. In the mean time the present article has been inserted to preserve in this work some memorial of a man who will always be dear to America, and to the wise and good in all nations.

WASHINGTON, a county of the District of Maine, and the most easterly land in the United States. It is bounded south by the ocean, west by Hancock county, north by Lower Canada, and east by New-Brunswick. It is about 200 miles in length, but its breadth is as yet undetermined. It was erected into a county in 1789; but has few towns yet incorporated. The coast abounds with excellent harbours. Although the winters are long and severe; yet the soil and productions are but little inferior to the other counties. The number of inhabitants in this county, according to the census of 1790, was 2758; but the increase since must have been very considerable. Chief town, Machias.—*Morse.*

WASHINGTON, a maritime county of the state of Rhode Island; bounded north by Kent, south by the N. Atlantic Ocean; west by the state of Connecticut, and east by Narraganset Bay. It is divided into seven townships, and contains 18,075 inhabitants, including 339 slaves. Chief town, South Kingstown.—*ib.*

WASHINGTON, a county of New York; bounded north by Clinton county, south by Rensselaer, south-west by Saratoga, west by Herkemer, and east by the State of Vermont. Until 1784 it was called Charlotte. It contained, in 1790, 14,042 inhabitants, including 742 slaves. In 1796, there were 3,370 of the inhabitants qualified electors. It is subdivided into 12 townships, of which Salem is the chief.—*ib.*

WASHINGTON, a county of Pennsylvania; situated in the south-west corner of the State; bounded north by Alleghany county, south by Monongalia county, in Virginia; east by Monongahela river, which divides it from Fayette county, and west by Ohio county in Virginia; agreeably diversified with hills, which admit of easy cultivation quite to their summits. It is divided into 21 townships, and contains 23,866 inhabitants, including 263 slaves. Mines of copper and iron ore have been found in this county.—*ib.*

WASHINGTON, the capital of the above county, and a post-town, is situated on a branch of Charter's Creek, which falls into Ohio river, a few miles below Pittsburg. It contains a brick court-house, a stone gaol, a large brick building for the public offices, an academy of stone, and nearly 100 dwelling-houses. It is 22 miles south-south-west of Pittsburg; 22 miles north-west of Brownsville, 60 miles north by west of Morgantown, in Virginia, and 325 west by north of Philadelphia. N. lat. 40 13, W. long. 80 6 40. It is remarkable for its manufactures, for so young a town. There are 3 other townships of the same name in Pennsylvania, viz. in Fayette, Franklin, and Westmoreland counties.

WASHINGTON, a county of Maryland, on the western shore of Chesapeak Bay; bounded north by the State of Pennsylvania; east by Frederick county, from which it is divided by South Mountain; south-west by Patowmack river, which divides it from the State of Virginia, and west by Sideling-Hill-Creek, which separates it from Alleghany county. This is called the garden of Maryland, lying principally between the North and South Mountains, and includes the rich, fertile and well cultivated valley of Conegocheague. Its streams furnish excellent mill-seats, and the lands are thought to be the most fertile in the State. Lime-stone and iron-ore are found here. Furnaces and forges have been erected,

erected, and conſiderable quantities of pig and bar iron are manufactured. Chief town, Elizabeth-Town.—*ib.*

WASHINGTON, a county of Virginia; bounded E. and N. E. by Wythe; north-weſt by Ruſſell; ſouth by the ſtate of North Carolina, and weſt by Lee. It is watered by the ſtreams which form Holſton, Clinch and Powell's rivers. There is a natural bridge in this county ſimilar to that in Rockbridge county. It is on Stock Creek, a branch of Peleſon river. It contains 5625 inhabitants, including 450 ſlaves. Chief town, Abingdon.—*ib.*

WASHINGTON, a diſtrict of the Upper Country of South Carolina, perhaps the moſt hilly and mountainous in the ſtate. It lies weſt of Ninety-Six diſtrict, of which it was formerly a part, and is bounded north by the ſtate of North Carolina. It contains the counties of Pendleton and Greenville; has 14,619 inhabitants, and ſends to the ſtate legiſlature five repreſentatives and two ſenators. Chief town, Pickenſville. A number of old deſerted Indian towns of the Cherokee nation, are frequently met with on the Keowee river, and its tributary ſtreams which water this country.—*ib.*

WASHINGTON, a county of Kentucky, bounded north-eaſt by Mercer, north-weſt by Nelſon, ſouth-eaſt by Lincoln, and weſt by Hardin.—*ib.*

WASHINGTON, a diſtrict of the State of Tenneſſee, ſituated on the waters of the rivers Holſton and Clinch, and is divided from Mero diſtrict on the weſt by an uninhabited country. It is divided into the counties of Waſhington, Sullivan, Greene, and Hawkins. It contained, according to the State cenſus of 1795, 29,531 inhabitants, including 4693 ſlaves.—*ib.*

WASHINGTON, a county of Tenneſſee, in the above diſtrict, contained in 1795, 10,105 inhabitants, incluſive of 978 ſlaves. Waſhington college is eſtabliſhed in this county by the legiſlature.—*ib.*

WASHINGTON, a county of the N. W. Territory, erected in 1788 within the following boundaries, viz. beginning on the bank of the Ohio where the weſtern line of Pennſylvania croſſes it, and running with that line to Lake Erie; thence along the ſouthern ſhore of that lake to the mouth of Cayahoga river, and up that river to the portage between it and the Tuſcarawa branch of Muſkingum; thence down that branch to the forks of the croſſing-place above Fort Lawrence; thence with a line to be drawn weſterly to the portage on that branch of the Big Miami, on which the fort ſtood which was taken from the French in 1752, until it meets the road from the Lower Shawaneſe town to Sanduſky; thence ſouth to the Sciota river to the mouth, and thence up the Ohio to the place of beginning.—*ib.*

WASHINGTON, a county of the Upper Diſtrict of Georgia, which contains 4,552 inhabitants, including 694 ſlaves. Fort Fidus is ſituated in the weſternmoſt part of the county, on the eaſt branch of Alatamaha river. The county is bounded on the N. E. by Ogeechee river. Numbers have lately moved here from Wilkes county, in order to cultivate cotton in preference to tobacco. This produce, though in its infancy, amounted to 208,000lbs. weight, in 1792. Chief town, Golphinton.—*ib.*

WASHINGTON, a townſhip of Vermont, Orange county, 12 miles weſt of Bradford, and contains 72 inhabitants.—*ib.*

WASHINGTON, a townſhip of Maſſachuſetts, in Berkſhire county, 7 miles ſouth-eaſt of Pittsfield, 8 eaſt of Lenox, and 145 weſt of Boſton. It was incorporated in 1777, and contains 588 inhabitants.—*ib.* Waſhington.

WASHINGTON, or *Mount Vernon*, a plantation of Lincoln county, Diſtrict of Maine, north-weſt of Hallowell, and 9 miles from Sterling. It conſiſts of 16,055 acres of land and water, of which the latter occupies 1641 acres. It contains 618 inhabitants, and was incorporated by the name of *Belgrade* in 1796.—*ib.*

WASHINGTON, a townſhip of New-York, in Dutcheſs county, bounded ſoutherly by the town of Beekman, and weſterly by Poughkeepſie and Clinton. It contains 5189 inhabitants, of whom 286 are electors, and 78 ſlaves.—*ib.*

WASHINGTON, a townſhip of New Hampſhire, in Cheſhire county, firſt called Camden. It was incorporated in 1776, and contains 545 inhabitants; it is 12 or 14 miles eaſt of Charleſtown.—*ib.*

WASHINGTON, a townſhip of Connecticut, in Litchfield county, about 7 miles ſouth-weſt of Litchfield.—*ib.*

WASHINGTON, a port of entry and poſt-town of N. Carolina, ſituated in Beaufort county, on the north ſide of Tar river, in lat. 35 30 N. 90 miles from Ocrecok Inlet, 40 from the mouth of Tar river, 61 ſouth-ſouth-weſt of Edenton, 38 north by eaſt of Newbern, 131 north-eaſt by north of Wilmington, and 460 from Philadelphia. It contains a court-houſe, gaol, and about 80 houſes. From this town is exported tobacco of the Peterſburg quality, pork, beef, Indian corn, peas, beans, pitch, tar, turpentine, roſin, &c. alſo pine boards, ſhingles, and oak ſtaves. About 130 veſſels enter annually at the cuſtom houſe in this town. The exports for a year, ending the 30th of September, 1794, amounted to 33,684 dollars.—*ib.*

WASHINGTON, a poſt-town of Kentucky, and the capital of Maſon county, about 3 miles ſouth by weſt of the landing at Limeſtone, on the ſouth ſide of Ohio river. It contains about 100 houſes, a Preſbyterian church, a handſome court-houſe and gaol; and is faſt increaſing in importance. It is 62 miles north-eaſt of Lexington, 75 north-eaſt by eaſt of Frankfort, and 709 ſouth-weſt by weſt of Philadelphia. N. lat. 38 40, W. long. 84 30.—*ib.*

WASHINGTON *Court-Houſe*, in S. Carolina, is 10 miles from Greenville, and 16 from Pendleton.—*ib.*

WASHINGTON, a poſt-town of Georgia, and the capital of Wilkes county, 50 miles north-weſt by weſt of Auguſta, 58 north by weſt of Louiſville, 28 from Greenſborough, and 813 from Philadelphia. It ſtands on the weſtern ſide of Kettle Creek, a north branch of Little river, which empties into Savannah river from the eaſtward, about 36 miles E. of the town. It is regularly laid out, and contained, in 1788, 34 houſes, a court-houſe, gaol, and academy. The funds of the academy amount to about 800l. ſterling, and the number of ſtudents to between 60 and 70. On the eaſt ſide of the town, a mile and a half diſtant, is a medicinal ſpring, which riſes from a hollow tree 4 or 5 feet in length. The inſide of the tree is covered with a coat of matter an inch thick, and the leaves around the ſpring are incruſted with a ſubſtance as white as ſnow. It is ſaid to be a ſovereign remedy for the ſcurvy, ſcrophulous diſorders, conſumptions, gout, and every other diſorder ariſing from humours in the blood. This ſpring

being

Washington. being situated in a fine, healthy part of the State, will no doubt be a pleasant and salutary place of resort for invalids from the maritime and unhealthy parts of Georgia, and the neighbouring states. N. lat. 33 12. —*ib.*

Washington *City*, in the territory of Columbia, was ceded by the State of Virginia and Maryland to the United States, and by them established as the seat of their government, after the year 1800. This city, which is now building, stands at the junction of the river Patowmack, and the Eastern Branch, latitude 38 53 N. extending nearly 4 miles up each, and including a tract of territory, exceeded in point of convenience, salubrity and beauty, by none in America. For although the land in general appears level, yet by gentle and gradual swellings, a variety of elegant prospects are produced, and a sufficient descent formed for conveying off the water occasioned by rain. Within the limits of the city are a great number of excellent springs; and by digging wells, water of the best quality may readily be had. Besides, the never-failing streams that now run through that territory, may also be collected for the use of the city. The waters of Reedy Branch, and of Tiber Creek, may be conveyed to the President's house. The source of Tiber Creek is elevated about 236 feet above the level of the tide in said Creek. The perpendicular height of the ground on which the capital stands, is 78 feet above the level of the tide in Tiber Creek. The water of Tiber Creek may therefore be conveyed to the capitol, and after watering that part of the city, may be destined to other useful purposes. The Eastern Branch is one of the safest and most commodious harbours in America, being sufficiently deep for the largest ships for about 4 miles above its mouth, while the channel lies close along the bank adjoining the city, and affords a large and convenient harbour. The Patowmack, although only navigable for small craft, for a considerable distance from its banks next the city, (excepting about half a mile above the junction of the rivers) will nevertheless afford a capacious summer harbour; as an immense number of ships may ride in the great channel, opposite to, and below the city. The situation of this metropolis is upon the great post-road, equi-distant from the northern and southern extremities of the Union, and nearly so from the Atlantic and Pittsburg, upon the best navigation, and in the midst of a commercial territory, probably the richest, and commanding the most extensive internal resource of any in America. It has therefore many advantages to recommend it, as an eligible place for the permanent seat of the general government; and as it is likely to be speedily built, and otherwise improved, by the public spirited enterprise of the people of the United States, and even by foreigners, it may be expected to grow up with a degree of rapidity hitherto unparalleled in the annals of cities. The plan of this city appears to contain some important improvements upon that of the best planned cities in the world, combining, in a remarkable degree, convenience, regularity, elegance of prospect, and a free circulation of air. The positions of the different public edifices, and for the several squares and areas of different shapes as they are laid down, were first determined on the most advantageous ground, commanding the most extensive prospects, and from their situation, susceptible of such improvements as either use or ornament may hereafter require. The capitol is situated on a most beautiful eminence, commanding a complete view of every part of the city, and of a considerable part of the country around. The President's house stands on a rising ground, possessing a delightful water prospect, together with a commanding view of the capitol, and the most material parts of the city. Lines, or avenues of direct communication, have been devised to connect the most distant and important objects. These transverse avenues, or diagonal streets, are laid out on the most advantageous ground for prospect and convenience, and are calculated not only to produce a variety of charming prospects, but greatly to facilitate the communication throughout the city. North and south lines, intersected by others running due east and west, make the distribution of the city into streets, squares, &c. and those lines have been so combined, as to meet at certain given points, with the divergent avenues, so as to form, on the spaces *first determined*, the different squares or areas. The grand avenues, and such streets as lead immediately to public places, are from 130 to 160 feet wide, and may be conveniently divided into foot-ways, a walk planted with trees on each side, and a paved way for carriages. The other streets are from 90 to 110 feet wide. In order to execute this plan, Mr Ellicot drew a true meridional line by celestial observation, which passes through the area intended for the capitol. This line he crossed by another, running due east and west, which passes through the same area. These lines were accurately measured, and made the bases on which the whole plan was executed. He ran all the lines by a transit instrument, and determined the acute angles by actual measurement, leaving nothing to the uncertainty of the compass. Washington, or the Federal City, is separated from Georgetown, in Montgomery county, Maryland, on the W. by Rock Creek, but that town is now within the territory of Columbia. It is 42 miles S. W. by S. of Baltimore, 876 from Passamaquoddy, in the District of Maine, 500 from Boston, 248 from New York, 144 from Philadelphia, 133 from Richmond, in Virginia, 232 from Halifax, in N. Carolina, 630 from Charleston, S. Carolina, and 794 from Savannah, in Georgia. —*ib.*

Washington, *Fort*, in the Territory N. W. of the Ohio, is situated on the north bank of the river Ohio, westward of Little Miami river, and 45 miles north-west of Washington, in Kentucky.—*ib.*

Washington, *Mount*, a small township of Massachusetts, Berkshire county, in the south-west corner of the state, 150 miles south-west by south of Boston. It was incorporated in 1779, and contains 261 inhabitants. —*ib.*

Washington, *Mount*, one of the White Mountains of New Hampshire, which makes so majestic an appearance all along the shore of the eastern counties of Massachusetts.—*ib.*

Washington's *Islands*, on the north-west coast of North America. The largest is of a triangular shape, the point ending on the southward at Cape St James's, in N. lat. 51 58. Sandy Point, at its north-east extremity, is in lat. 54 22 N. Its longitude west extends from Hope Point, the north-west extremity 226° 37′ to Sandy Point, in 228° 45′. Port Ingraham, Perkins and Magee Sound lie on the western side of the island; on the

the eaſtern ſide are the following ports from north to ſouth—Skeetkiſs, or Skitkiſs Harbour, Port Cummaſhawa, Kleiws Point, Smoke Port, Kanſkeeno Point, Port Geyers, Port Ueah, and Port Sturgis. Capt. Cook, when he paſſed this iſland, ſuppoſed it to be a part of the continent, as the weather at the time was thick, and the wind boiſterous, which obliged him to keep out at ſea, till he made the weſtern cape of the continent in about lat. 55 N. Capt. Dixon diſcovered theſe iſlands in 1787, and named them Queen Charlotte's Iſlands. Capt. Gray diſcovered them in 1789, and called them Waſhington's Iſlands. There are three principal iſlands, beſides many ſmall ones. It is conjectured that they make a part of the Archipelago of St Lazarus.—*ib.*

WASKEMASHIN, an iſland in the Gulf of St Lawrence, on the coaſt of Labrador. N. lat. 50 3, W. long. 59 55.—*ib.*

WATAGUAKI *Iſles*, on the coaſt of Labrador, and in the Gulf of St Lawrence, lies near the ſhore, north-eaſt of Ouapitougan Iſle, and ſouth-weſt of Little Mecatina, about 10 or 12 leagues from each.—*ib.*

WATAUGA, a river of Tenneſſee, which riſes in Burke county, North-Carolina, and falls into Holſton river, 15 miles above Long-Iſland.—*ib.*

WATCH *Point*, lies to the northward of Fiſher's Iſland, in Long-Iſland Sound, and weſt-ſouth-weſt 7 leagues from Block Iſland.—*ib.*

WATCHWORK. Our intention in this article does not extend to the manual practice of this art, nor even to all the parts of the machine. We mean to conſider the moſt important and difficult part of the conſtruction, namely, the method of applying the maintaining power of the wheels to the regulator of the motion, ſo as not to hurt its power of regulation. Our obſervations would have come with more propriety under the title SCAPEMENT, that being the name given by our artiſts to this part of the conſtruction. Indeed they were intended for that article, which had been unaccountably omitted in the body of the Dictionary under the words CLOCK and WATCH. But the bad health and occupations of the perſon who had engaged to write the article, have obliged us to defer it to the laſt opportunity which the alphabetical arrangement affords us; and, even now, the ſame cauſes unfortunately prevent the author from treating the ſubject in the manner he intended and which it well deſerves. But we truſt that, from the account which is here given, the reader, who is converſant in mathematical philoſophy will perceive the juſtneſs of the concluſions, and that an intelligent artiſt will have no heſitation in acceding to the propriety of the maxims of conſtruction deduced from them.

The regulator of a clock or watch is a pendulum or a balance. Without this check to the motion of the wheels, impelled by a weight or a ſpring, the machine would run down with a motion rapidly accelerating, till friction and the reſiſtance of the air induced a ſort of uniformity, as they do in a kitchen jack. But if a pendulum be ſo put in the way of this motion, that only one tooth of a wheel can paſs it at each vibration, the revolution of the wheels will depend on the vibration of the pendulum. This has long been obſerved to have a certain conſtancy, inſomuch that the aſtronomers of the Eaſt employed pendulums in meaſuring the times of their obſervations, patiently counting their vibrations during the phaſes of an eclipſe or the tranſits of the ſtars, and renewing them by a little puſh with the finger when they became too ſmall. Gaſſendi, Riccioli, and others, in more recent times, followed this example. The celebrated phyſician Sanctorius is the firſt perſon who is mentioned as having applied them as regulators of clock movements. Machines, however, called *clocks*, was a train of toothed wheels, leading round an index of hours, had been contrived long before. The earlieſt of which we have any account is that of Richard of Wallingford, Abbot of St Alban's, in 1326 (A). It appears to have been regulated by a fly like a kitchen jack*. Not long after this Giacomo Dondi made one at Padua, which had a *motus ſuccuſſorius*, a hobbling or trotting motion; from which expreſſion it ſeems probable that it was regulated by ſome alternate movement. We cannot think that this was a pendulum, becauſe, once it was introduced, it never could have been ſupplanted by a balance. The alternate motion of a pendulum, and its ſeeming uniformity, are among the moſt familiar obſervations of common life; and it is ſurpriſing that they were not more early thought of for regulating time meaſurers. The alternate motions of the old balance is one of the moſt far-fetched means that can be imagined, and might paſs for the invention of a very reflecting mind, while a pendulum only requires to be drawn aſide from the plumb-line, to make it vibrate with regularity. The balance muſt be put in motion by the clock, and that motion muſt be ſtopped, and the contrary motion induced; and we muſt know that the ſame force and the ſame checks will produce uniform oſcillations. All this muſt be previouſly known before we can think of it as a regulator; yet ſo it is that clocks, regulated by a balance, were long uſed, and very common through Europe, before Galileo propoſed the pendulum, about the year 1600. Pendulum clocks then came into general uſe, and were found to be greatly preferable to balance clocks as accurate meaſurers of time. Mathematicians ſaw that their vibrations had ſome regular dependance on uniform gravity, and in their writings we meet with many attempts to determine the time and demonſtrate the iſochroniſm of the vibrations. It is amuſing to read theſe attempts. We wonder at the awkwardneſs and inſufficiency of the explanation given of the motions of pendulums, even by men of acknowledged eminence. Merſennus carried on a moſt uſeful correſpondence with all the mathematicians of Europe, and was the means of making them acquainted with each other; nay, he was himſelf well converſant in the ſcience; yet one cannot but ſmile at his reaſonings on this ſubject. Standing on the ſhoulders of our predeceſſors, we look around us, in great ſatisfaction with our own powers of obſervation, not thinking how we are raiſed up, or that we are trading with the ſtock left

* Conrad Geſneri Epitome, p. 604.

(A) Profeſſor Beckmann, in the firſt volume of his *Hiſtory of Inventions*, expreſſes a belief that clocks of this kind were uſed in ſome monaſteries ſo early as the 11th century, and that they were derived to the monks from the Saracens. His authorities, however, are diſcordant, and ſeem not completely ſatisfactory even to himſelf.

Watch-work.

left us by the diligent and sagacious philosophers of the 17th century (B). Riccioli, Gassendus, and Galileo, made similar attempts to explain the motion of pendulums; but without success. This honour was reserved for Mr Huyghens, the most elegant of modern geometers. He had succeeded in 1656 or 1657 in adapting the machinery of a clock to the maintaining of the vibrations of a pendulum. Charmed with the accuracy of its performance, he began to investigate with scrupulous attention the theory of its motion. By the most ingenious and elegant application of geometry to mechanical problems, he demonstrated that the wider vibrations of a pendulum employed more time than the narrower, and that the time of a semicircular vibration is to that of a very small one nearly as 34 to 29; and aided by a new department of geometrical science invented by himself, namely, the evolution of curves, he shewed how to make a pendulum swing in a cycloid, and that its vibrations in this curve are all performed in equal times, whatever be their extent.

But before this time, Dr Hooke, the most ingenious and inventive mechanician of his age, had discovered the great accuracy of pendulum clocks, having found that the manner in which they had been employed had obscured their real merit. They had been made to vibrate in very large arches, the only motion that could be given them by the contrivances then known; and in 1656 he invented another method, and made a clock which moved with astonishing regularity. Using a heavy pendulum, and making it swing in very small arches, the clocks so constructed were found to excel Mr Huyghens's cycloidal pendulums; and those who were unfriendly to Huyghens had a sort of triumph on the occasion. But this was the result of ignorance. Mr Huyghens had shewn, that the error of $\frac{1}{100}$ of an inch, in the formation of the parts which produced the cycloidal motion, caused a greater irregularity of vibration than a circular vibration could do, although it should extend five or six degrees on each side of the perpendicular. It has been found that the unavoidable inaccuracies, even of the best artists, in the cycloidal construction, make the performance much inferior to that of a common pendulum vibrating in arches which do not exceed three or four degrees from the perpendicular. Such clocks alone are now made, and they exceed all expectation.

We have said that a pendulum needed only to be removed from the perpendicular, and then let go, in order to vibrate and measure time. Hence it might seem, that nothing is wanted but a machinery so connected with the pendulum as to keep a register, as it were, of the vibration. It could not be difficult to contrive a method of doing this; but more is wanted. The air must be displaced by the pendulum. This requires some force, and must therefore employ some part of the momentum of the pendulum. The pivot on which it swings occasions friction—the thread, or thin piece of metal by which it is hung, in order to avoid this friction, occasions some expenditure of force by its want of perfect flexibility or elasticity. These, and other causes, make the vibrations grow more and more narrow by degrees, till at last the pendulum is brought to rest. We must therefore have a contrivance in the wheelwork which will restore to the pendulum the small portion of force which it loses in every vibration. The action of the wheels therefore may be called a *maintaining power*, because it keeps up the vibrations.

But we now see that this may affect the regularity of vibration. If it be supposed that the action of gravity renders all the vibrations isochronous, we must grant that the additional impulsion by the wheels will destroy that isochronism, unless it be so applied that the sum total of this impulsion and the force of gravity may vary so with the situation of the pendulum, as still to give a series of forces, or a law of variation, perfectly similar to that of gravity. This cannot be effected, unless we know both the law which regulates the action of gravity, producing isochronism of vibration, and the intensity of the force to be derived from the wheels in every situation of the pendulum.

The necessary requisite for the isochronous motion of the pendulum is, that the force which urges it toward the perpendicular, be proportional to its distance from it (see DYNAMICS, n° 103. Cor. 7. *Suppl.*); and therefore, since pendulums swinging in small circular arches are sensibly isochronous, we must infer that such is the law by which the accelerating action of gravity on them is really accommodated to every situation in those arches.

It will greatly conduce to the better understanding of the effect of the maintaining power, if the reader keep in continual view the chief circumstances of a motion of this kind. Therefore let AC*d* (fig. 1.) represent the arch passed over by the pendulum, stretched out into a straight line. Let C be its middle point, when the pendulum hangs perpendicular, and A and *a* be the extremities of the oscillation. Let AD be drawn perpendicular to AC, to represent the accelerating action of gravity on the pendulum when it is at A. Draw the straight line DC*d*, and *ad*, perpendicular to A*a*. About C, as a centre, describe the semicircle AFH*a*. Through any points B, K, *k*, *b*, &c. of A*a*, draw the perpendiculars BFE, KLM, &c. cutting both the straight line and the semicircle. Then, Plate XLVIII.

1. The actions of gravity on the pendulum, when in the situations B, K, &c. by which it is urged toward C, are proportional to, and may be represented by, the ordinates BE, KL, *be*, *kl*, &c. to the straight line DC*d*.

2. The velocities acquired at B, K, &c. by the acceleration along AB, AK, &c. are proportional to the ordinates BF, KM, &c. to the semicircle AH*a*; and, therefore, the velocity with which the pendulum passes through the middle point C, is to its velocity in any other point B, as CH to BF.

3. The times of describing the parts AB, BK, KC, &c. of the whole arch of oscillation, are proportional to, and may be represented by, the arches AF, FM, MH, &c. of the semicircle.

4. If

(B) We are provoked to make this observation, by observing at this moment, in a literary journal, a pert and petulant upstart speaking of Newton's optical discoveries in terms of ridicule and abuse, employing these very discoveries to diminish his authority. Is it not thus that Christianity is now slighted by those who enjoy the fruits of the pure morality which it introduced?

Watch-work.

4. If one pendulum defcribe the arch reprefented by ACa, and another defcribe the arch KCk, they will defcribe them in equal times, and their maximum velocities (viz. their velocities in the middle point), are proportional to AC and KC; that is, the velocities in the middle point are proportional to the width of the ofcillations.

The fame proportions are true with refpect to the motions outwards from C. That is, when the pendulum defcribes CA, with the initial velocity CH, its velocity at K is reduced to KM by the retarding action of gravity. It is reduced to BF at B, and to nothing at A; and the times of defcribing CK, KB, BA, CA, are as HM, HF, HA. Another pendulum fetting out from C, with the initial velocity CO, reaches only to K, CK being = CO. Alfo the times are equal.—If we confider the whole ofcillation as performed in the direction Aa, the forces AD, BE, KL accelerate the pendulum, and the fimilar forces ad, be, kl, on the other fide, retard it. The contrary happens in the next ofcillation aCA.

5. The areas DABE, DAKL, &c. are proportional to the fquares of the velocities acquired by moving along AB, AK, &c. or to the diminution of the fquares of the velocities fuftained by moving outwards along BA or KA, &c.

The confideration of this figure will enable the reader (even though not a mathematician) to form fome notion of the effect of any propofed application of a maintaining power by means of wheelwork: For, knowing the weight of the pendulum, we know the accelerating action of that weight in any particular fituation A of the pendulum. We alfo know what addition or fubtraction we produce on the pendulum in that fituation by the wheel-work. Suppofe it is an addition of preffure equal to a certain number of grains. We can make AD to $D\delta$ as the firft to the laft; and then $A\delta$ will be the whole force urging the pendulum toward C. Doing the fame for every point of AC, we obtain a line $\delta\epsilon\lambda c$, which is a new fcale of forces, and the fpace $DC\delta$, comprehended between the two fcales CD and $C\delta$, will exprefs the addition made to the fquare of the velocity in paffing along AC by the joint action of gravity and the maintaining power. Alfo, by drawing a line $\kappa\pi$ perpendicular to AC, making the fpace $C\pi\kappa$ equal to CAD, the point π will be the limit of the ofcillation outward from C, where the initial velocity HC is extinguifhed. If the line $\kappa\pi$ cut the fame circle in θ, one-half the arch θA will nearly exprefs the contraction made in the time of the outward ofcillation by the maintaining power. An accurate determination of this laft circumftance is operofe, and even difficult; but this folution is not far from the truth, and will greatly affift our judgment of the effect of any propofal, even though $\kappa\pi$ be drawn only by the judgment of the eye, making the area left out as nearly equal to the area taken in as we can eftimate by infpection. This is faid from experience.

Since the motion of a pendulum or balance is alternate, while the preffure of the wheels is conftantly in one direction, it is plain that fome art muft be ufed to accommodate the one to the other. When a tooth of the wheel has given the balance a motion in one direction, it muft quit it, that it may get an impulfion in the oppofite direction. The balance or pendulum thus efcaping from the tooth of the wheel, or the tooth efcaping from the balance, has given to the general contrivance the name of SCAPEMENT among our artifts, from the French word *echappement*. We proceed, therefore, to confider this fubject more particularly, firft confidering the fcapements which are peculiarly fuited to the fmall vibrations of pendulums, and then thofe which muft produce much wider vibrations in balances. This, with fome other circumftances, render the fcapements for pendulums and balances very different.

I. *Of the Action of a Wheel and Pallet.*

THE fcapement which has been in ufe for clocks and watches ever fince their firft appearance in Europe, is extremely fimple, and its mode of operation is too obvious to need much explanation. In fig. 2. XY reprefents a horizontal axis, to which the pendulum P is attached by a flender rod, or otherwife. This axis has two leaves C and D attached to it, one near each end, and not in the fame plane, but fo that when the pendulum hangs perpendicularly, and at reft, the piece C fpreads a few degrees to the right hand, and D as much to the left. They commonly make an angle of 70, 80, or 90 degrees. Thefe two pieces are called PALLETS. AFB reprefents a wheel, turning round on a perpendicular axis EO, in the order of the letters AFEB. The teeth of this wheel are cut into the form of the teeth of a faw, leaning forward, in the direction of the motion of the rim. As they fomewhat refemble the points of an old-fafhioned royal diadem, this wheel has got the name of the CROWN WHEEL. In watches it is often called the *balance wheel*. The number of teeth is generally odd; fo that when one of them B is preffing on a pallet D, the oppofite pallet C is in the fpace between two teeth A and I. The figure reprefents the pendulum at the extremity of its excurfion to the right hand, the tooth A having juft efcaped from the pallet C, and the tooth B having juft dropped on the pallet D. It is plain, that as the pendulum now moves over to the left, in the arch PG, the tooth B *continues* to prefs on the pallet D, and thus accelerates the pendulum, both during its defcent along the arch PH, and its afcent along the arch HG. It is no lefs evident, that when the pallet D, by turning round the axis XY, raifes its point above the plane of the wheel, the tooth B efcapes from it, and I drops on the pallet C, which is now nearly perpendicular. I preffes C to the right, and accelerates the motion of the pendulum along the arch GP. Nothing can be more obvious than this action of the wheel in maintaining the vibrations of the pendulum. We can eafily perceive, alfo, that when the pendulum is hanging perpendicularly in the line XH, the tooth B, by preffing on the pallet D, will force the pendulum a little way to the left of the perpendicular, and will force it fo much the farther as the pendulum is lighter; and, if it be fufficiently light, it will be forced fo far from the perpendicular that the tooth B will efcape, and then I will catch on C, and force the pendulum back to P, where the whole operation will be repeated. The fame effect will be produced in a more remarkable degree, if the rod of the pendulum be continued through the axis XY, and a ball Q put on the other end to balance P. And, indeed, this is the contrivance which was firft applied to clocks all over Europe, before the application of the pendulum. They were

were balance clocks. The force of the wheel was of a certain magnitude, and therefore able, during its action on a pallet, to communicate a certain quantity of motion and velocity to the balls of the balance. When the tooth B escapes from the pallet D, the balls are then moving with a certain velocity and momentum. In this condition, the balance is checked by the tooth I catching on the pallet C. But it is not instantly stopped. It continues its motion a little to the left, and the pallet C forces the tooth I a little backward. But it *cannot* force it so far as to escape over the top of the tooth I; because all the momentum of the balance was generated by the force of the tooth B; and the tooth I is equally powerful. Besides, when I catches on C, and C continues its motion to the left, its lower point applies to the face of the tooth I, which now acts on the balance by a long and powerful lever, and soon stops its farther motion in that direction, and now, continuing to press on C, it urges the balance in the opposite direction.

Thus we see that in a scapement of this kind, the motion of the wheel must be very hobbling and unequal, making a great step forward, and a short step backward, at every beat. This has occasioned the contrivance to get the name of the RECOILING SCAPEMENT, the recoiling pallets. This hobbling motion is very observable in the wheel of an alarm.

Thus have we obtained two principles of regulation. The first and most obvious, as well as the most perfect, is the natural isochronous vibration of a pendulum. The only use of the wheelwork here, besides registering the vibrations, is to give a gentle impulsion to the pendulum, by means of the pallet, in order to compensate friction, &c. and thus maintain the vibrations in their primitive magnitude. But there is no such native motion in a balance, to which the motion of the wheels must accommodate itself. The wheels, urged by a determined pressure, and acting through a determined space (the face of the pallet), must generate a certain determined velocity in the balance; and therefore the time of the oscillation is also determined, both during the progressive and the retrograde motion of the wheel. The actions being similar, and through equal spaces, in every oscillation, they must employ the same time. Therefore a balance, moved in this manner, must be isochronous, and a regulator for a time-keeper.

By thus employing a balance, the horizontal position of the axis XY is unnecessary. Accordingly, the old clocks had this axis perpendicular, by which means the whole weight of the balance rested on the point of the pivot Y or X, according as the balance PQ was placed above or below. By making the supporting pivot of hard steel, and very sharp, friction was greatly diminished. Nay, it was entirely removed from this part of the machine by suspending the balance by a thread at the end X, instead of allowing it to rest on the point of the pivot Y.

As the balance regulator of the motion admits of every position of the machine, those clocks were made in an infinite variety of fanciful forms, especially in Germany, a country famous for mechanical contrivances. They were made of all sizes, from that of a great steeple clock, to that of an ornament for a lady's toilet. The substitution of a spring in place of a weight, as a first mover of the wheel-work, was a most ingenious thought. It was very gradual. We have seen, in the Emperor's museum at Brussels, an old (perhaps the first) spring clock, the spring of which was an old sword blade, from the point of which a catgut was wound round the barrel of the first wheel. Some ingenious German substituted the spiral spring, which both took less room, and produced more revolutions of the first wheel.

When clocks had been reduced to such small sizes, the wish to make them portable was very natural; and the means of accomplishing this were obvious, namely, a farther reduction of their size. This was accomplished very early; and thus we obtained pocket watches, moved by a spiral spring, and regulated by a balance with the recoiling scapement, which is still in use for common watches. The hobbling motion of the crown wheel is very easily seen in all of them.

It is very uncertain who first substituted a pendulum in place of the balance (CLOCK, *Encycl.*). Huyghens, as we have already observed, was the first who investigated the motions of pendulums with success, and his book *De Horologio Oscillatorio* may be considered as the elements of refined mechanics, and the source of all the improvements that have been made in the construction of scapements. But it is certain that Dr Hooke had employed a pendulum for the regulation of a clock many years before the publication of the abovementioned treatise, and he claims the merit of the invention of the *only proper* method of employing it. We imagine therefore that Dr Hooke's invention was nothing more than a scapement for a pendulum making small vibrations, without making use of the opposite motions of the two sides of the crown wheel. Dr Hooke had contrived some scapement more proper for pendulums than the recoiling pallets, because certainly those might be employed, and are actually employed as a scapement for pendulum clocks to this day, although they are indeed very ill adapted to the purpose. He had not only remarked the great superiority of such pendulum clocks as were made before Huyghens's publication of the cycloidal pendulum over the balance clocks, but had also seen their defects, arising from the light pendulums and wide arches of vibration, and invented a scapement of the nature of those now employed. The pendulum clock which he made in 1658 for Dr Wilkins, afterwards Bishop of Chester, is mentioned by the inventor as peculiarly suited to the moderate swing of a pendulum; and he opposes this circumstance to a general practice of wide vibrations and trifling pendulums. The French are not in the practice of ascribing to us any thing that they can claim as their own; yet Lepaute says that the *Echappement à l' Ancre* came from England about the year 1665. It is also admitted by him that clock-making flourished in England at that time, and that the French artists went to London to improve in it. Putting these and other circumstances together, we think it highly probable that we are indebted to Dr Hooke for the scapement now in use. The principle of this is altogether different from the simple pallets and direct impulse already described; and is so far from being obvious, that the manner of action has been misunderstood, even by men of science, and writers of systems of mechanics.

In this scapement we employ those teeth of the wheel which are moving in one direction; whereas in the former

former ſcapement, oppoſite teeth were employed moving in contrary directions. Yet even here we muſt communicate an alternate motion to the axis of the pallets. The contrivance, in general, was as follows: On the axis A (See fig. 3.) of the pendulum or balance is fixed a piece of metal BAC, called the CRUTCH by our artiſts, and the ANCHOR by the French. It terminates in two faces B *b* C *c* of tempered ſteel, or of ſome hard ſtone. Theſe are called the PALLETS, and it is on them that the teeth of the wheel act. The faces B *b* C *c* are ſet in ſuch poſitions that the teeth puſh them out of the way. Thus B puſhes the pallet to the left, and C puſhes its pallet to the right. Both puſh their pallets ſidewiſe outward from the centre of the wheel. The pallet B is uſually called the *leading*, and C the *driving* pallet by the artiſts, although it appears to us that theſe names ſhould be reverſed, becauſe B *drives* the pallet out of the way, and C *pulls* or leads it out of the way. They might be called the *firſt* and *ſecond* pallet, in the order in which they are acted on by the wheel. We ſhall uſe either denomination. The figure is accommodated to the inactive or reſting poſition of the pendulum Suppoſe the pendulum drawn aſide to the right at Q, and then let go. It is plain that the tooth B, preſſing on the face of the pallet β B *b* all the way from β to *b*, thruſts it aſide outwards, and thus, by the connection of the crutch with the pendulum rod, aids the pendulum's motion along the arch QPR. When the pendulum reaches R, the point of the tooth B has reached the angle *b* of the pallet, and eſcapes from it. The wheel preſſing forward, another tooth C drops on the pallet face C *c*, and, by preſſing this pallet outward, evidently aids the pendulum in its motion from R to P. The tooth C eſcapes from this pallet at the angle *c*, and now a tooth B′ drops on the firſt pallet, and again aids the pendulum; and this operation is repeated continually.

The mechaniſm of this communication of motion is thus explained by ſeveral writers of elements. The tooth B (fig. 2.) is urged forward in the direction BD, perpendicular to the radius MB of the SWING WHEEL. It therefore preſſes on the pallet, which is moveable only in the direction BE, perpendicular to BA the radius of the pallet. Therefore the force BD muſt be reſolved into two, *viz.* BE, in the direction in which alone the pallet can move, and ED, or BF, perpendicular to that direction. The laſt of theſe only preſſes the pallet and crutch againſt the pivot hole A. BE is the only uſeful force, or the force communicated to the pallet, enabling it to maintain the pendulum's motion, by reſtoring the momentum loſt by friction and other cauſes.

But this is a very erroneous account of the *modus operandi*, as may be ſeen at once, by ſuppoſing the radius of the pallets to be a tangent to the wheel. This is a poſition moſt frequently given to them, and is the very poſition in fig. 3. In this caſe MB is perpendicular to BA, and therefore BD will coincide with BA, and there will be no ſuch force as BE to move the pendulum. It is a truth deducible from what we know of the mechanical conſtitution of ſolid bodies, and confirmed by numberleſs obſervations, that when two ſolid bodies preſs on each other, either in impulſion or in dead preſſure, the direction in which the mutual preſſure is exerted is always perpendicular to the touching ſurfaces, whatever has been the direction of the impelling body (See IMPULSION, *Suppl.* n° 66. MACHINERY, *Suppl.* n° 35. and ſeveral other parts of this Work.) Moreover this preſſure is mutual, equal, and oppoſite. Whatever the ſhapes of the faces of the tooth and pallet, we can draw a plane BN, which is the common tangent to both ſurfaces, and a line HBI through the point of contact perpendicular to BN. It is farther demonſtrated in the article MACHINERY, *Suppl.* n° 35, &c. that the action of the wheel on the pendulum is the ſame as if the whole crutch were annihilated, and in its ſtead there were two rigid lines AH, MI, from the centres of the crutch and wheel, perpendicular to HI, and connected by a third rigid line or rod HI, touching the two in H and I.

For if a weight V be hung at *v*, the extremity of the horizontal radius M *v* of the wheel, it will act on the lever *v* MI, preſſing its point I upwards in the direction IH perpendicular to MI; the upper end of this rod IH will, in like manner, preſs the extremity H of the rod HA, and this will urge the pendulum from P toward R. To withſtand this, the pendulum rod AP may be withheld by a weight *z*, hanging by a thread on the extremity of the horizontal lever A *z*, equal to M *v*, and connected with the crutch and pendulum. The weights V and *z* may be ſo proportioned to each other that by acting perpendicularly on the crooked levers *v* MI, and *z* AH, the preſſures at H and I ſhall be equal, and juſt balance each other by the intervention of the rod HI. When this is the caſe, we have put things into the ſame mechanical ſtate, in reſpect of mutual action, as is effected by the crutch, pallets, and wheel, which, in like manner, produce equal preſſures at B the point of contact, in the direction BH and BI. The weight V may be ſuch as produces the very ſame effect at B that is produced by the previous train of wheel-work. The weight *z* therefore muſt be juſt equal to the force produced by the wheel-work on the point *z* of the pendulum rod, becauſe by acting in the oppoſite direction it juſt balances it. Let us ſee therefore what force is communicated to the pendulum by the wheels.

Let x be the upward preſſure excited at I, and y the equal oppoſite preſſure excited at H. Then, by the property of the lever, we have $MI : Mv = V : x$, and $x \times MI = V \times Mv$. In like manner $y \times AH = Z \times Az$. Therefore, becauſe $x = y$, and $Az = Mv$, we have $V : Z = MI : AH$. That is, the force exerted by the tooth of the wheel in the direction of its motion is to the force impreſſed on the pendulum rod at a diſtance equal to the radius of the wheel as MI to AH. The force impreſſed on the ball of the pendulum is leſs than this in the proportion of AP to A *z*, or M *v*.

Cor. 1. If the perpendiculars MN, AV, be drawn on the tangent plane, the forces at B and *z* will be as BN to BO. For theſe lines are reſpectively equal to MI and AH.

Cor. 2. If HI meet the line of the centres AC in S, the forces will be as SM to SA; that is $V : Z = SM : SA$.

Cor. 3. If the face β B *b* of the pallet be the evolutrix of a circle deſcribed with the radius AH, and the face of the tooth be the evolutrix of a circle deſcribed with the radius MI, the force impreſſed on the pendulum

dulum by the wheels will be conſtant during the whole vibration (MACHINERY, n° 36.) But theſe are not the only forms which produce this conſtancy. The forms of teeth deſcribed by different authors, ſuch as De la Hire, Camus, &c. for producing a conſtant force in trains of wheel-work, will have the ſame effect here. It is alſo eaſy to ſee that the force impreſſed on the pendulum may be varied according to any law, by making theſe faces of a proper form. Therefore the face, from B outwards, may be ſo formed that the force communicated to the pendulum by the wheels, during its deſcent from Q to P, may be in one conſtant proportion to the acceleration of gravity, and then the ſum of the forces will be ſuch as produce iſochronous vibrations. If the inner part B *b* of the face be formed on the ſame principle, the difference of the forces will have the ſame law of variation. If the face *β b* be the evolutrix of a circle, and the tooth B terminate in a point gently rounded, or quite angular, the force on the pendulum will continually increaſe as the tooth ſlides from *β* to *b*. For the line AH continues of the ſame magnitude, and MI diminiſhes. The contrary will happen, if the pallet be a point, either ſharp or rounded, and if the face of the tooth be the evolutrix now mentioned; for MI will remain the ſame, while AH diminiſhes. If the tooth be pointed, and *β b* be a ſtraight line, the force communicated to the pendulum will diminiſh, while the tooth ſlides from *β* to *b*. For in this caſe AH diminiſhes and MI increaſes.

Cor. 4. In general the force on the pendulum is greater as the angle MB *b* increaſes, and as AB *b* diminiſhes.

Cor. 5. The angular velocity of the wheel is to that of the pendulum, in any part of its vibration, as AH to MI. This is evident, becauſe the rod IH moving (in the moment under conſideration) in its own direction, the points H and I move through equal ſpaces, and therefore the angles at A and M muſt be inverſely as the radii.

All that has now been ſaid of the firſt pallet AB may be applied to the ſecond pallet AC.

If the perpendiculars C *s* be drawn to the touching plane *o* C *n*, cutting AM in *s*, we ſhall have V : *z* = *s* M : *s* A, as in Cor. 2. And if the perpendiculars M *i*, A *h*, be drawn on C *s*, we have V : Z = M *i* : A *h*, as in the general theorem. The only difference between the action on the two pallets is, that if the faces of both are plain, the force on the pendulum increaſes during the whole of the action on the pallet C, whereas it diminiſhes during the progreſs of the tooth along the other pallet.

The reader will doubtleſs remark that each tooth of the wheel acts on both pallets in ſucceſſion; and that, during its action on either of them, the pendulum makes one vibration. Therefore the number of vibrations during one turn of the wheel is double the number of the teeth: conſequently, while the tooth ſlides along one of the pallets, it advances half the ſpace between two ſucceſſive teeth; and when it eſcapes from the pallet, the other tooth *may* be juſt in contact with the other pallet. We ſay it *may* be ſo; in which caſe there will be no dropping of the teeth from pallet to pallet. This, however, requires very nice workmanſhip, and that every tooth be at preciſely the ſame diſtance from its neighbour. Should the tooth which is juſt going to apply to a pallet chance to be a little too far advanced on the wheel, it would touch the pallet before the other had eſcaped. Thus, ſuppoſe that before B eſcapes from the point *b* of the pallet, the tooth C is in contact with the pallet CG, B cannot eſcape. Therefore when the pendulum returns from R towards Q, the pallet *β b*, returning along with it, will puſh back the tooth B of the wheel. It does this in oppoſition to the force of the wheel. Therefore, whatever motion the wheel had communicated to the pendulum, during its ſwing from P to Q, will now be taken from it again. The pendulum will not reach Q, becauſe it had been aided in its motion from Q, and had proceeded further than it would have done without this help. Its motion toward Q is further diminiſhed by the friction of the pallet. Therefore it will now return again from ſome nearer point *q*, and will not go ſo far as in the laſt vibration, but will return through a ſtill ſhorter arch: And this will be ſtill more contracted in the next vibration, &c. &c. Thus it appears that if a tooth chances to touch the pallet before the eſcape of the other, the wheel will advance no farther, and ſoon after the pendulum will be brought to reſt.

For ſuch reaſons it is neceſſary to allow one tooth to eſcape *a little before* the other reaches the pallet on which it is to act, and to allow a ſmall drop of the teeth from pallet to pallet. But it is accounted bad workmanſhip to let the drop be conſiderable, and *cloſe ſcapement* is accounted a mark of care and of good workmanſhip. It is evidently an advantage, becauſe it gives a longer time of action on each pallet. This freeing the ſcapement cannot be accompliſhed by filing ſomething from the face of the tooth; becauſe this being done to all, the diſtance between them is diminiſhed rather than augmented. The pallets muſt be firſt ſcaped as cloſe as poſſible. This obliges the workman to be careful in making the teeth equidiſtant. Then a ſmall matter is taken from the point of each pallet, by filing off the back *b r* of the pallet. The tooth will now eſcape before it has moved through half a ſpace.

From all that has been ſaid on this particular, it appears that the interval between the pallets muſt comprehend a certain number of teeth, and half a ſpace more.

The firſt circumſtance to be conſidered in contriving a ſcapement is the angular motion that is intended to be given to the pendulum during the action of the wheel. This is uſually called the *angle of ſcapement*, or the *angle of action*. Having fixed on an angle *a* that we think proper, we muſt ſecure it by the poſition and form of the face of the pallets. Knowing the number of teeth in the ſwing-wheel, divide 180° by this number, and the quotient is the angle *b* of the wheel's motion during one vibration of the pendulum. In the line AM, joining the centres of the crutch and wheel, make SM to SA, and *s* M to *s* A, as the angle *a* to the angle *b*; and then, having determined how many teeth ſhall be comprehended between the pallets, call this number *n*. Multiply the angle *b* by *n* + 1, and take the half of the product. Set off this half in the circumference of the wheel (at the points of the teeth) on each ſide of the line joining the centres of the crutch and wheel, as at TB and TC. Through S and *s* draw SB and *s* C, and through B draw *β* B *b* perpendicular to SB, for the medium poſition of the face of the firſt pallet; that is, for

for its position when the pendulum hangs perpendicular. In like manner, drawing oCn perpendicular to sC, we have the medium position of the second pallet. The demonstration of this construction is very evident from what has been said.

We have hitherto supposed that the pendulum finishes its vibration at the instant that a tooth of the wheel escapes from a pallet, and another tooth drops on the other pallet. But this is never, or should never be, the case. The pendulum is made to swing somewhat beyond the angle of scapement: for if it do not when the clock is clean and in good order, but stop precisely at the drop of a tooth, then, when it grows foul, and the vibration diminishes, the teeth will not escape at all, and the clock will immediately stop. Therefore the force communicated by the wheels during the vibration within the limits of scapement, must be increased so as to make the pendulum *throw* (as the artists term it) farther out; and a clock is more valued when it throws out considerably beyond the angle of scapement. There are good reasons for this. The momentum of the pendulum, and its power to regulate the clock (which Mr Harrison significantly called its *dominion*), is proportional to the width of its vibrations very nearly.

This circumstance of exceeding the angle of scapement has a very great influence on the performance of the clock, or greatly affects the dominion of the pendulum. It is easy to see that, when the face βb of the leading pallet is a plane, if the pendulum continue its motion to the right, from P toward Q, after the tooth B has dropped on it, the pallet will push the wheel back again, while the tooth slides outward on the pallet toward β. Such pallets therefore will make a *recoiling scapement*, resembling, in this circumstance, the old pallet employed with the crown wheel, and will have the properties attached to this circumstance. One consequence of this is, that it is much affected by any inequalities of the maintaining power. It is a matter of the most familiar observation, that a common watch goes slower when within a quarter of an hour of being down, when the action of the spring is very weak, in consequence of its not pulling by a radius of the fusee. We observe the same thing in the beating of an alarum clock. Also if we at any time press forward the wheelwork of a common watch with the key, we observe its beats accelerate immediately. The reason of this is pretty plain. The balance, in consequence of the acceleration in the angle of scapement, would have gone much farther, employing a considerable time in the excursion. This is checked abruptly, which both shortens the vibration and the time employed in it. In the return of the pendulum, the motion is accelerated the whole way, along an arch which is shorter than what corresponds to its velocity in the middle point; for it is again checked on the other side, and does not make its full excursion. Moreover, all this irregularity of force, or the great deviation from a resistance to the excursion proportional to the distance from the middle point, is exerted on the pendulum when it is near the end of the excursion, where the velocity being small, this irregular force acts long upon it, at the very time that it has little force wherewith to resist it. All temporary inequalities of force, therefore, will be more felt in this situation of the balance than if they had been exerted in the middle of its motion. And although the regulating power of a pendulum greatly exceeds that of the light balances used in pocket watches, something of the same kind may be expected even in pendulum clocks. Accordingly this appears by a series of experiments made by Mr Berthoud, a celebrated watchmaker of Paris. A clock, with a half second pendulum weighing five drams, was furnished with a recoiling scapement, whose pallets were planes. The angle of scapement was $5\frac{1}{2}$ degrees. When actuated with a weight of two pounds, it swung 8°, and lost 15″ per hour; with four pounds, it swung 10°, and lost 6″. Thus it appears that by doubling the maintaining power, although the vibration was increased in consequence of the greater impulse, the time was lessened 9″ per hour, viz. about $\frac{1}{400}$. It is plain, from what was said when we described the first scapement, that an increase of maintaining power must render the vibration more frequent. We saw, on that occasion, that, even when the gravity of the pendulum is balanced by a weight on the other end of the rod, the force of the wheels will produce a vibratory motion, and that an augmentation of this force will increase it, or make the vibrations more rapid. The precise effect of any particular form of teeth can be learned only by computing the force on the pendulum in every position, and then constructing the curve $\delta \epsilon \lambda C$ of fig. 1. The rapid increase of the ordinates beyond those of the triangle ADC, forms a considerable area $DA\pi o$, to compensate the area $\kappa o C$, and thus makes a considerable contraction $A\pi$ of the vibration, and a sensible contraction $\frac{A\theta}{2}$ of the time.

Mr George Graham, the celebrated watchmaker in London, was also a good mathematician, and well qualified to consider this subject scientifically. He contrived a scapement, which he hoped would leave the pendulum almost in its natural state. The acting face of the pallet abc (fig. 4) is a plane. The tooth drops on a, and escapes from c, and is on the middle point b when the pendulum is perpendicular. Beyond a, the face of the pallet is an arch ad, whose centre is A, the centre of the crutch. The maintaining power is made so great as to produce a much greater vibration than the angle of active scapement aAc. The consequence of this is that, when the tooth drops on the angle a, the pendulum, continuing its motion, carries the crutch along with it, and the tooth passes on the arch ad, in a direction passing through the centre of the crutch. This pressure can neither accelerate nor retard the motion of the crutch and pendulum. As the pendulum was accelerated after it passed the perpendicular, by the other pallet, it will (if quite unobstructed) throw out farther than what corresponds to the velocity which it had in the middle point of its vibration; perhaps till the tooth passes from a to e on the circular arch of the pallet. But although it sustains no contrary action from the wheels during this excursion beyond the angle of scapement, it will not proceed so far, but will stop when the tooth reaches d; because there must be some resistance arising from the friction of the tooth along the arch ad, and from the clamminess of the oil employed to lubricate it: but this resistance is exceedingly minute, not amounting to $\frac{1}{8}$th of the pressure on the arch. Nay, we think that it appears from the experiments of Mr Coulomb that, in the case of such minute pressures preffures on a furface covered with oil, there is no fenfible retardation analogous to that produced by friction, and that what retardation we obferve arifes entirely from the clamminefs of the oil. We are fo imperfectly acquainted with the manner in which friction and vifcidity obftruct the motions of bodies, that we cannot pronounce decifively what will be their effect in the prefent cafe. Friction does not increafe much, if at all, by an increafe of velocity, and appears like a fixed quantity when the preffure is given. This makes all motions which are obftructed by friction terminate abruptly. This will fhorten both the length and the time of the outward excurfion of the pendulum. The vifcidity of the oil refifts differently, and more nearly in the proportion of the velocities. The diminution of motion will not be in this proportion, becaufe in the greater velocities it acts for a fhorter time. Were this accurately the cafe, the refiftance of vifcidity would alfo be nearly conftant, and it would operate as friction does. But it does not ftop a motion abruptly, and the motions are extinguifhed gradually. Therefore, although vifcidity muft always diminifh the extent of the excurfion, it may fo vary as not to diminifh the time. We apprehend, however, that it generally does. But whatever happens in the excurfion, the return will certainly be flower, and employ more time than if it had not been obftructed, becaufe the velocity in every point is lefs than if perfectly free. The whole arch, confifting of a returning arch and an excurfion on the other fide, may be either flower or quicker, according as the compenfation is complete or not, or is even overdone.

All thefe reflections occurred to Mr Graham; and he was perfuaded that the time of the tooth's remaining on the arch *a d*, both afcending and defcending, would differ very little from that of the defcription of the fame arch by a free pendulum. The great caufes of irregularity feemed to be removed, viz. the inequalities in the action of the wheels in the vicinity of the extremity of the vibration, where the pendulum having little momentum is, long in the fame little fpace, expofed to their action. The derangement produced by any force depends on the time of its action, and therefore muft be greateft when the motion is floweft. The pendulum gets its impulfe in the very middle of its vibration, where its velocity is the greateft; and therefore the inequalities of the maintaining power act on it only for a fhort time, and make a very trifling alteration in the time of its defcribing the arch of fcapement. Beyond this, it is nearly in the ftate of a free pendulum; nay, even though it be affected by an inequality of the maintaining power, and it be accelerated beyond its ufual rate in that arch, the chief effect of this will be to caufe it to defcribe a larger arch of excurfion. The fhortening of the time of this defcription by the friction will be the fame as before, happening at the very end of the excurfion; but the return will be more retarded by the friction on a longer arch. And, by this, a compenfation may be made for the trifling contraction of the time of defcribing the arch of fcapement.

This circumftance of giving the impulfe in the middle of the vibration, where its time of action is the fmalleft poffible, and whereby the pendulum is fo long left free from the action of the wheels, is of the very firft importance in all fcapements, and fhould ever be in the mind of the mechanician. When this is adhered to, the form of the face *abc* is fcarcely of any moment. Much has been written on this form, and many attempts have been made to make it fuch that the action of the wheels fhall be proportional to the action of gravity. To do this is abfolutely impoffible. Mr Graham made them planes, not only becaufe of eafieft execution, but becaufe a plane really confpires pretty well with the change of gravity. While the pendulum moves from Q to P (fig. 3.), the force of gravity, acting in the direction QP, is continually diminifhing. So is the accelerating power of the pallet from *a* to *b*. When the pendulum rifes from P to R, a force in the oppofite direction RP continually increafes. This is analogous to the continual diminution of a force in the direction PR. Now we have fuch a diminution of fuch a force, in the action of the pallet from *b* to *c*, and fuch an augmentation in the action of the other pallet.

For all thefe reafons, this conftruction of a fcapement appeared very promifing. Mr Graham put it in practice, and it anfwered his moft fanguine expectation, and is now univerfally adopted in all nice clocks. Mr Graham, however, did not think it prudent to caufe a tooth to drop on the very angle *a* of the pallet. He made it drop on a point *f* of the arch of excurfion. This has alfo the advantage of diminifhing the angle of action, which we have proved to be of fervice. It requires, indeed, a greater maintaining power; but this can eafily be procured, and is lefs affected by the changes to which it is liable by the effect of heat and cold on the oil. Our obfervations on the effects of friction and vifcidity in the arch *a d* feem to be confirmed by the obfervations of feveral artifts, who agree in faying that a great increafe of maintaining power increafes the vibrations, but makes them perceptibly flower. When they wrote, much oil was applied to diminifh the friction on the arch of repofe; but, fince that time, the rubbing parts were made fuch as required no oil, and this retardation difappeared. In the clock of the tranfit room of the Royal Obfervatory, the angle of action feldom exceeds one-third of the fwing of the pendulum. The pallets are of oriental ruby, and the wheel is of fteel tempered to the utmoft degree of hardnefs. This clock never varies a whole fecond from equable motion in the courfe of five days.

This contrivance is known by the name of the DEAD BEAT, the DEAD SCAPEMENT; becaufe the feconds index ftands ftill after each drop, whereas the index of a clock with a recoiling fcapement is always in motion, hobbling backward and forward.

Thefe fcapements, both recoiling and dead beat, have been made in a thoufand forms; but any perfon tolerably acquainted with mechanics, will fee that they are all on the fame principles, and differ only in fhape or fome equally unimportant circumftance. Perhaps the moft convenient of any is that reprefented in fig. 5. where the fhaded part is the crutch, made of brafs or iron, and A and B are two pieces of agate, flint, or other hard ftone, cut into the proper fhape for a pallet of either kind, and firmly fixed in proper fockets. They project half an inch, or thereabouts, in front of the crutch, fo that the fwing wheel is alfo before the crutch, diftant about $\frac{1}{10}$th of an inch or fo. Pallets of ruby, driven by a hard fteel fwing wheel, need no oil, but merely to be once rubbed clean with an oily cloth.

Sometimes the wheel has pins inftead of teeth. They are

are ranged round the rim of the wheel, perpendicular to its plane, and both pallets are on one ſide of the wheel, ſtanding perpendicular to its plane. One of theſe pins drops from the firſt to the ſecond pallet at once. The pallets are placed on two arms, as in fig. 6. in which caſe the pins are alternately on different ſides of the wheel; or on one, as in fig. 7. By the motion of the pendulum to the right, the pin (in fig. 7.), after reſting on the concave arch *da*, acts on the face *ac*, and drops from *c* on the other concave arch *ig*, which continues to move a little way to the right. It then returns, and the pin ſlides and acts on the pallet *ib*, and eſcapes at *b*; and the next pin is then on the arch of repoſe *da*.

It being evident that the recoiling ſcapement accelerates the vibrations beyond the rate of a free pendulum, and it alſo appearing to many of the firſt artiſts that the dead ſcapement retards them, they have attempted to form a ſcapement which ſhall avoid both of theſe defects, by forming the arches *a d*, *i g*, ſo as to produce a very ſmall recoil. Mr Berthoud does this in a very ſimple manner, by placing the centre of *a d* at a ſmall diſtance from that of the crutch, ſo as to make the riſe of the pallet above the concentric arch about one-third of the arch itſelf. Applying ſuch a crutch to the light pendulum mentioned in a former paragraph, he found that doubling, and even trebling the maintaining power, produced no change in the time of vibration, though it increaſed the width from 8° to 12° and 14°. We have no doubt of the efficacy of this contrivance, and think it very proper for all clocks which require much oil, ſuch as turret clocks, &c. But we apprehend that no rule can be given for the angle that the recoiling arch ſhould make with the concentric one. We imagine that this depends entirely on the ſhare which friction and oil have in producing the retardation of the dead beat.

Other artiſts have endeavoured to avoid the inconveniences of friction and oil on the arch of repoſe in another way. Inſtead of allowing the tooth of the wheel to drop on the back of the pallet, which we called the *arch of excurſion*, and others call the *arch of repoſe*, it drops on a detent *o t a* (fig. 8.), of which the part *t a* is part of an arch whoſe centre is A, the centre of the crutch, and the part *t o* is in the direction of the radius. This piece does not adhere to the pallet, but is on the end of an arm *o* A, which turns round the axis A of the crutch on fine pivots: it is made to apply itſelf to the back of the pallet by means of a ſlender ſpring A*p*, attached to the pallet, and preſſing inward on a pin *p*, fixed in the arm of the detent. When ſo applied, its arch *t a* makes the repoſe, and its point *a* makes a ſmall portion of the face *a c* of the pallet.

The action of this apparatus is very eaſily underſtood. When a tooth eſcapes from the ſecond pallet, by the motion of the pendulum from the left to the right, another tooth drops on this pallet (which the figure ſhews to be the firſt or leading pallet) at the angle *t*, and reſts on the ſmall portion *t a* of an arch of repoſe. But the crutch continuing its motion to the right, immediately quits the arm *o* A, carrying the pallet *a c r* along with it, and leaving the wheel locked on the detent *o t a*. By and bye the pendulum finiſhes its excurſion to the right, and returns. When it enters the arch of action, the pallet has applied itſelf to the detent *o t a*, and withdraws it from the tooth. The tooth immediately acts on the face *a c* of the pallet, and reſtores the motion loſt during the laſt vibration. The uſe of the ſpring is merely to keep the detent applied to the pallet without ſhaking. It is a little bent during their ſeparation, and adds ſomething of an oppoſing force to the aſcent of the pendulum on the other ſide of the wheel, and accelerates its return. A ſimilar detent on the back of the ſecond pallet performs a ſimilar office, ſupporting the wheel while the pendulum is beyond the arch of ſcapement, and quitting it when the pendulum enters that arch.

We do not know who firſt practiſed this very ingenious and promiſing invention. Mr Mudge certainly did ſo early as 1753 or 1754. Mr Berthoud ſpeaks obſcurely of contrivances of the ſame nature. So does Le Roy, and (we think) Le Paute. We ſay that it is very promiſing. Friction is almoſt annihilated by transferring it to the pivots at A; ſo that, in the excurſion beyond the angle of ſcapement, the pendulum ſeems almoſt free. Indeed ſome artiſts of our acquaintance have even avoided the friction of the pivots at A, by making the arm of the detent a ſpring of conſiderable thickneſs, except very near to A, where it is made very thin and broad. But we do not find that this conſtruction, though eaſily executed, and ſuſceptible of great preciſion and ſteadineſs of action, is much practiſed. We preſume that the performance has not anſwered expectations. It has not been ſuperior to the incomparably more ſimple dead ſcapement of Graham. Indeed we think that it cannot. A part of the friction ſtill remains, which cannot be removed; namely, while the arch *t a* is drawn from between the tooth and pallet. Nay, we apprehend that ſomething more than friction muſt be overcome here. The tooth is apt to force the detent outward, unleſs the part *t a* be a little elevated at its point *a* like a claw, above the concentric arch, and the face of the tooth be made to incline forward, ſo as to fit this ſhape of the detent. This will conſume ſome force, when the momentum of the pendulum is by no means at its maximum. Should the clock be foul, and the excurſions beyond ſcapement be very ſmall, this diſturbance muſt be exceedingly pernicious. But we have a much greater objection. During the whole excurſion beyond ſcapement, there is a new force of a ſpring acting on the pendulum, which deviates conſiderably from the proportions of the accelerating power of gravity. It does not commence its action till the detent ſeparates from the arm of the crutch. Then the ſpring of the detent acts as a retarding force againſt the excurſion of the pendulum, now on the other ſide, bringing it ſooner to reſt, and then accelerating it in its way back to the beginning of the arch of ſcapement. In ſhort, this conſtruction ſhould have the properties of a recoiling ſcapement. We got a clock-maker to make ſome experiments on one which he had made for an amateur, which fully confirmed our conjecture. When the detent ſpring was ſtrong, an increaſe of maintaining power made the vibrations both wider and more rapid. The artiſt reduced the ſtrength of the ſpring till this effect was rendered very ſmall. It might perhaps be quite removed by means of a ſtill weaker ſpring: But the ſpring was already ſo weak that a hard ſtep on the floor of the room did ſometimes diſengage the detent from the wheel. It appears, therefore, that nothing can be reaſonably expected from this conſtruction that

that is not as well performed by the dead ſcapement of Mr Graham, of much eaſier execution, and more certain performance.

Very ſimilar to this conſtruction (at leaſt in the excurſion beyond the angle of ſcapement) is the conſtruction of Mr Cumming, and it has the ſame defects. His pallets are carried, as in the one deſcribed, by the crutch. The detents preſs on them behind by their weight only: therefore when the tooth is locked on the detent of one pallet, its weight is taken off from the pendulum on that ſide, and the weight of the detent on the other ſide oppoſes the aſcent, and accelerates the deſcent of the pendulum.

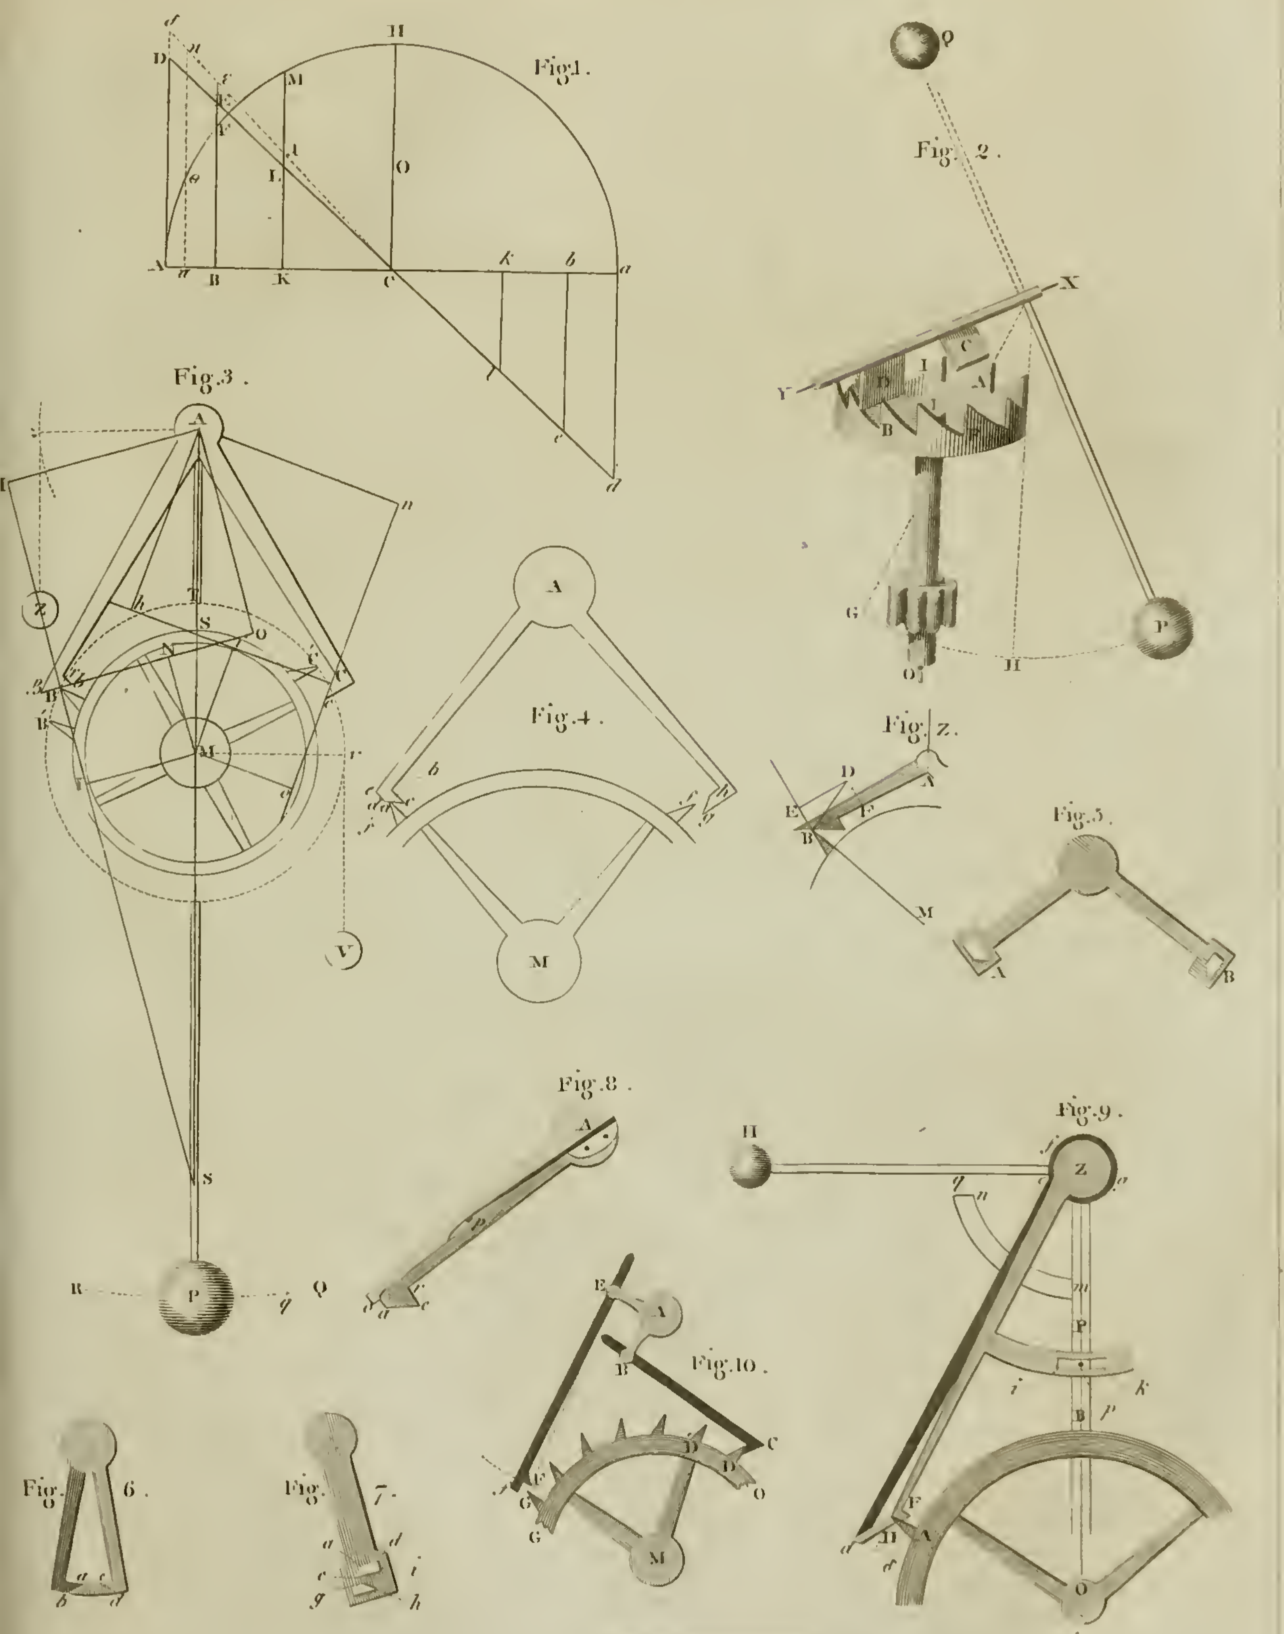
Mr Cumming executed another ſcapement, conſiſting, like thoſe, of a pallet and detent. But the manner of applying the maintaining power is extremely different in principle from any yet deſcribed. It is exceedingly ingenious, and ſeems to do all that is poſſible for removing every ſource of irregularity in the maintaining power, and every obſtruction to free motion ariſing from friction and oil in the ſcapement. For this reaſon we ſhall give ſuch an account of its eſſential circumſtances as may ſuffice to give a clear conception of its manner of acting, and its good properties and defects; but referring the inquiſitive reader to Mr Cumming's Elements of Clock and Watch Work, publiſhed in 1766, for a more full account.

In the ſcapements laſt deſcribed, the pallets were fixed to the crutch and pendulum, and the maintaining power, during its action, was applied to the pendulum by means of the pallets, in the ſame way as in ordinary ſcapements. The detents were unconnected with the pendulum, and it was free during the whole excurſion. In the preſent ſcapement both the pallets and detents are detached from the pendulum, except in the moment of unlocking the wheel; ſo that the pendulum may be ſaid to be free during its whole vibration, except during this ſhort moment.

ABC (fig. 9.) repreſents a portion of the ſwing wheel, of which O is the centre, and A one of the teeth; Z is the centre of the crutch, pallets, and pendulum. The crutch or detent is repreſented of a form reſembling the letter A, having in the circular croſs piece a ſlit *i k*, alſo circular, Z being the centre. This form is very different from Mr Cumming's, and inferior to his, but was adopted here in order to avoid a long deſcription. The arm ZF forms the firſt detent, and the tooth A is repreſented as locked on it at F. D is the firſt pallet on the end of the arm Z *d* moveable round the ſame centre with the detents, but moveable independently of them. The arm *d e*, to which the pallet D is attached, lies altogether behind the arm ZF of the detent, being fixed to a round piece of braſs *e f g*, which has pivots turning concentric with the verge or axis of the pendulum. To the ſame round piece of braſs is fixed the horizontal arm *e* H, carrying at its extremity the ball H, of ſuch ſize that the action of the tooth A on the pallet D is juſt able (but without any riſk of failing) to raiſe it up to the poſition here drawn. ZP*p* repreſents the fork, or the pendulum rod, behind both detent and pallet. A pin *p* projects forward, coming through the ſlit *i k*, without touching the upper or under margin of it. There is alſo attached to the fork the arm *m n* (and a ſimilar one on the other ſide), of ſuch length that, when the pendulum rod is perpendicular, as is repreſented here, the angular diſtance of *n q* from the rod *e q* H is preciſely equal to the angular diſtance of the left ſide of the pin *p* from the left end *i* of the ſlit *i k*.

The mode of action on this apparatus is abundantly ſimple. The natural poſition of the pallet D is at *δ*, repreſented by the dotted lines, reſting on the back of the detent F. It is naturally brought into this poſition by its own weight, and ſtill more by the weight of the ball H. The pallet D, being ſet on the fore ſide of the arm at Z, comes into the ſame plane with the detent F and the ſwing-wheel. It is drawn, however, in the figure in another poſition. The tooth C of the wheel is ſuppoſed to have eſcaped from the ſecond pallet, on which the tooth A immediately engages with the pallet D, ſituated at *δ*, forces it out, and then reſts on the detent F, the pallet D leaning on the tip of the tooth. F is brought into this ſituation in a way that will appear preſently. After the eſcape of C, the pendulum, moving down the arch of ſemivibration, is repreſented as having attained the vertical poſition. Proceeding ſtill to the left, the pin *p* reaches the extremity *i* of the ſlit *i k*; and, at the ſame inſtant, the arm *n* touches the rod *e* H in *q*. The pendulum proceeding a hair's breadth further, withdraws the detent F from the tooth, which now even puſhes off the detent, by acting on the ſlant face of it. The wheel being now unlocked, the tooth following C on the other ſide acts on its pallet, puſhes it off, and reſts on its detent, which has been rapidly brought into a proper poſition by the action of A on the ſlant face of F. It was a ſimilar action of C on its detent, in the moment of eſcape which brought F into a fit poſition for locking the wheel by the tooth A. The pendulum ſtill going on, the arm *m n* carries the weight of the ball H, and the pallet connected with it, and it comes to reſt before the pin *p* again reaches the end of the ſlit, which had been ſuddenly withdrawn from it by the action of A on the ſlant face of F. The pendulum now returns towards the right, loaded on the left with the ball H, which reſtores the motion which it had loſt during the laſt vibration. When, by its motion to the right, the pin *p* reaches the end *k* of the ſlit *i k*, it unlocks the wheel on the right ſide. At the ſame inſtant the weight H ceaſes to act on the pendulum, being now raiſed up from it by the action of a tooth like B on the pallet D.

Let us now conſider the mechaniſm of theſe motions. The prominent feature of the contrivance is the almoſt complete diſengagement of the regulator from the wheels. The wheels, indeed, act on the pallets; but the pallets are then detached from the pendulum. The ſole uſe of the wheel is to raiſe the little weights while the pendulum is on the other ſide, in order to have them in readineſs at the arrival of the pendulum. They are then laid on the pendulum, and ſupply an accelerating force, which reſtores to the pendulum the momentum loſt during the preceding vibration. Therefore no inequalities in the action of the wheel on the pallets, whether ariſing from friction or oil, has any effect on the maintaining power. It remains always the ſame, namely, the rotative momentum of the two weights. The only circumſtance, in which the irregularity of the action of the wheels can affect the pendulum is at the moment of unlocking. Here indeed the regulator may be affected; but this moment is ſo ſhort, in compariſon with other



Lowry sc.

other fcapements, that it muft be confidered as a real improvement.

It is very uncandid to refufe the author a claim to the character of an ingenious artift on account of this contrivance, as has been done by a very ingenious univerfity Profeffor, who taxes Mr Cumming with ignorance of the *firft elements of mechanics*, and fays that the beft thing in his book is his advice to fufpend the pendulum from a great block of marble, firmly fixed in the wall*. This is certainly a good advice, and we doubt not but that the Profeffor's clock would have performed ftill better if he had condefcended to follow it. It is ftill lefs candid to queftion the originality of the invention. We know for certain that it was invented at a time and place where the author *could* not know what had been done by others. It would have been more like the urbanity of a well-educated man to have acknowledged the genius, which, without fimilar advantages, had done fo much.

* See Ludlam's Essay.

But while we thus pay the tribute of juftice to Mr Cumming, we do not adopt all his opinions. The clock has the fame defects of the former in refpect of the laws of the force which accelerates the pendulum. The fudden addition of the fmall weight, and this almoft at the extremity of the vibration, would derange it very much, if the addition were fufceptible of any fenfible variation. The irregularity of the action of the wheels *may* fenfibly affect the motion during the unlocking, when the clock is foul, and the pendulum *juft* able to unlock; for any difturbance at the extremity of the vibration greatly affects the time. We acknowledge that the parts which we here fuppofe to be foul may not be fo in the courfe of twenty years, thefe parts being only the pivots of the fcapement. The great defect of the fcapement is its liablenefs to unlock by any jolt. It is more fubject to this than the others already mentioned. This rifk is much increafed by the flender make of the parts, in Mr Cumming's drawings, and in the only clock of the kind we have feen; but this is not neceffary: and it fhould be avoided for another reafon; the interpofing fo many flender and crooked parts between the moving power and the pendulum weakens the communication of power, and requires a much more powerful wheelwork.

All thefe, however, are flight defects, and only the laft can be called a fault. The clocks made on this principle have gone remarkably well, as may be feen by the regifters of his majefty's private obfervatory. But the greateft objection is, that they do not perform better than a well-made dead fcapement; and they are vaftly more troublefome to make and to manage. This is ftrictly true, and is a ferious objection. The fact is, that the dominion of a heavy pendulum is fo great, that if *any one* of the fcapements now defcribed be well executed with pallets of agate, and a wheel of hard fteel, and if the pendulum be fufpended agreeably to Mr Cumming's advice, there is hardly any difference to be obferved in their performance. We fhall content ourfelves with a fingle proof of this from fact. The clock invented by the celebrated Harrifon is *at leaft equal* in its performance to any other. Friction is almoft annihilated, and no oil is required. It went fourteen years without being touched, and during that time did not vary one complete fecond from one day to another, nor ever deviated half a minute by accumulation from equable motion: Yet the fcapement, in fo far as it refpects the law of the accelerating force, deviates more from the proportion of the fpaces than the moft recoiling fcapement that ever was put to a good clock. It is fo different from all hitherto defcribed, both in form and principle, that we muft not omit fome account of it, and with it we fhall conclude our fcapements for clocks.

Let GDO reprefent the fwing-wheel, of which M is the centre. A is the verge or axis of the pendulum. It has two very fhort arms AB, AE. A flender rod BC turns on fine pivots in the joint B, and has at its extremity C a hook or claw, which takes hold of a tooth D of the fwing-wheel when the pendulum moves from the right fide to the left. This claw, when at liberty, ftands at right angles, or, at leaft, in a certain determinate angle, with regard to the arm AB; and when drawn a little from that pofition, it is brought back to it again by a very flender fpring. The arm AE is furnifhed with a detent EF, which alfo, when at liberty, maintains its pofition on the arm by means of a very flender fpring.

Let us now fuppofe that the tooth D is preffing on the claw C, while the pendulum is moving to the right. The joint B yields, by its motion round A, to the preffure of the tooth on the claw. By this yielding, the angle ABC opens a little. In the mean time, the fame motion round A caufes the point F of the detent on the other fide to approach the circumference of the wheel in the arch of a circle, and the tooth G at the fame time advances. They meet, and the point of G is lodged in the notch under the projecting heel *f*. When this takes place, it is evident that any farther motion of the point E round A muft pufh the tooth G a little backward, by means of the detent EF. It cannot come any nearer to the wheel, becaufe the point of the tooth ftops the heel *f*. The inftant that F pufhes G back, the tooth D is withdrawn from the claw C, and C flies out, by the action of its fpring, and refumes its pofition at right angles to BA; and the wheel is now free from the claw, but is pufhing at the detent F (c). The pendulum, having finifhed its excurfion to the right (in which it caufes the wheel to recoil by means of the detent F), returns toward the left. The wheel now advances again, and by preffing on F, aids the pendulum through the whole angle of fcapement. By this motion the claw C defcribes an arch of a circle round A, and approaches the wheel, till it take hold of another tooth, namely, the one following D, and pulls it back a little. This immediately frees the detent F from the preffure of the tooth G, and it flies out a little from the wheel, refuming its natural pofition by means of

(c) The reader may here remark the manner in which the preffure of the tooth G on the detent is transferred to the joint E by the intervention of the fhank FE, and from the joint E to the pendulum rod, by the intervention of the arm EA. This communication of preffure is precifely the fame that we made ufe of in explaining the common fcapement. MG, FE, and EA, in this fig. 10. are performing the offices which we then gave to the lines MB, BH, and HA, in fig. 3. Harrifon's pallet realifes the abftract theory.

of its fpring. Soon after, the motion of the pendulum to the left ceafes, and the pendulum returns; D pulling forward the hook C to aid the pendulum, and the former operation is repeated, &c. &c.

Such is the operation of the pallets of Harrifon and Hindley. Friction is almoft totally avoided, and oil entirely (D). The motion is given to the pendulum by a fair pull or pufh, and the teeth of the wheel only apply themfelves to the detents without rubbing. There is no drop, and the fcapement makes no noife, and is what the artifts call *a filent fcapement*. The mechanician will readily perceive, that by properly difpofing the arms AB, AE, and difpofing the pallets on the circumference of the wheel, the law, by which the action of the wheel on the pendulum is regulated, may be greatly varied, fo as to harmonize, as far as the nature of fcapement, alternately pufhing and pulling, will admit, with the action of gravity.

But this is evidently a recoiling fcapement, and one of the worft kind; for the recoil is made at the very confines of the vibration, where every difturbance of the regular cycloidal vibration occafions the greateft difturbance to the motion. Yet this clock kept time with moft unexampled precifion, far excelling all that had been made before, and equal to any that have been made fince. This is entirely owing to the immenfe fuperiority of the momentum of the pendulum over the maintaining power.

II. *Of Scapements for a Watch.*

The execution of a proper fcapement for watches is a far more delicate and difficult problem than the foregoing, on account of the fmall fize, which requires much more accurate workmanfhip, becaufe the error of the hundredth part of an inch has as great a proportion to the dimenfions of the regulator as an inch in a common houfe clock. It is much more difficult on another account. We have no fuch means of accumulating fuch a dominion (to ufe Mr Harrifon's expreffive term) over the wheel-work in the regulator of a watch as in that of a clock. The heavieft balance that we can employ, without the certainty of fnapping its pivots by every flight jolt, is a mere trifle, in comparifon with the pendulum of the moft ordinary clock. A dozen or twenty grains is the utmoft weight of the balance, even of a very large pocket watch. The only way that we can accumulate any notable quantity of regulating power in fuch a fmall pittance of matter is by giving it a very great velocity. This we do by accumulating all its weight in the rim, by giving it very wide vibrations, and by making them extremely frequent. The balance-rim of a middling good watch fhould pafs through at leaft ten inches in every fecond. Now, when we reflect on the fmall momentum of this regulator, the inevitable inequalities of the maintaining power, and the great arch of vibration on which thefe inequalities will operate, and the comparative magnitude even of an almoft infenfible friction or clamminefs, it appears almoft chimerical to expect any thing near to equability in the vibrations, and incredible that a watch can be made which will not vary more than one beat in 86400. Yet fuch have been made. They muft be confidered as the moft mafterly exertions of human art. The performance of a reflecting telefcope is a great wonder: the worft that can find a market muft have its mirrors executed without an error of the ten-thoufandth part of an inch; but we now know that this accuracy is attained almoft in fpite of us, and that we fcarcely *can* make them of a worfe figure. But the cafe is far otherwife in watch-work. Here all thofe wonderful approaches to perfection are the refults of rational difcuffion, by means of found principles of fcience; and, unlefs the artift who puts thefe principles into practice be more than a mere copyift, unlefs the principles themfelves are perceived by him, and actually direct his hand, the watch may ftill be good for nothing. Surely, then, this is a liberal art, and far above a manual knack. The ftudy of the means by which fuch wonders are fteadily effected, is therefore the ftudy of a gentleman.

In the account given above of the fcapements for pendulums, we affumed as one leading principle that *the natural vibrations of a pendulum are performed in equal times, whether wide or narrow.* This is fo nearly true, when the arches on each fide of the perpendicular do not exceed four degrees, that the retardation of the wider arches within that limit will not become fenfible, though accumulated for a long time. The common fcapement with a plane face of the pallet, helps to correct even this fmall inequality much better than the niceft form of the cycloidal checks propofed by Huyghens.

In watch-work we affume a fimilar principle, namely, that *the ofcillations of a balance, urged by its fpring, and undifturbed by all foreign forces, are performed in equal times, whether they be wide or narrow.* This principle was affumed by the celebrated mechanician Dr Robert Hooke, on the authority of many experiments which he had made on the bending and unbending of fprings. He found that the force neceffary for retaining a fpring in any conftrained pofition was proportional to its tenfion, or deflection from its natural form. He expreffed this in an anagram, which he publifhed about the year 1660, in order to eftablifh his claim to the difcovery, and yet conceal it, till he had made fome important application of it. When the anagram was explained fome years afterwards, it was, "*Ut tenfio, fic vis.*" Dr Hooke thought of applying this difcovery to the regulation of watch movements. For, if a flender fpring be *properly* applied to the axis of a watch balance, it will put that balance in a certain determinate pofition. If the balance

(D) Mr Harrifon was at firft by profeffion a carpenter in a country place. Being extremely ingenious and inventive, he had made a variety of curious wooden clocks. He made one, in particular, for a turret in a gentleman's houfe. Its expofure made it wafte oil very faft, and the maker was often obliged to walk two or three miles to renew it, and got nothing for his trouble. In trudging home, not in very good humour, he pondered with himfelf how to make a clock go without oil. He changed all his pinion leaves into rollers; which anfwered very well. But the pallets required it more than any other part. After various other projects, he contrived thofe now reprefented, where there was no friction, and no oil is wanted. The turret clock continued to go without being touched till Mr Harrifon left the country.

lance be turned aside from this position, it seems to follow that it will be urged back toward it by a force proportional to its distance from it. He immediately made the application to an old watch, which he afterward gave to Dr Wilkins, Bishop of Chester. This was in 1658. Its motion was so amazingly improved, that Hooke was persuaded of the perfection of his principle, and thought that nothing was now wanting for making a watch of this kind a perfect chronometer but the hand of a good workman. For his watch seemed almost perfect, though made in a small country town, in a very coarse manner. Mr Huyghens also claims this discovery. He published his claim about the year 1675, and proposed to make watches for discovering the longitude of a ship at sea. But there is the most unquestionable evidence of Dr Hooke's priority by fifteen years, and of his having made several watches of this kind. One of them was in the possession of his majesty king Charles II. Dr Hooke's first balance spring was straight, and acted on the balance in a very imperfect manner. But he soon saw the imperfections, and made several successive alterations; and, among others, he employed the cylindrical spiral now employed by Mr Arnold; but he gave it up for the flat spiral: and the king's watch had one of this kind before Mr Huyghens published his invention. His project of longitude watches had been carried on along with Lord Brouncker and Sir Robert Moray, and they had quarrelled some years before that publication. See WATCH, *Encycl.*

But both Dr Hooke and Mr Huyghens were too sanguine in their expectations. We, by no means, have the evidence for the truth of this principle that we have for the accelerating action of gravity on a pendulum. It rests on the nicety and the propriety of the experiments; and long experience has shewn that it is sensibly true only within certain limits. The demonstrations by which Bernoulli supports the unqualified principle of Mr Huyghens, proceed on hypothetical doctrines concerning the nature of elasticity. And even these shew that the law of elasticity which he assumed was selected, not because founded on simpler principles than any other, but because it was consistent with the experiments of Hooke and Huyghens. Besides, although this should be the true law of a spring, it does not follow that this spring, applied in *any way* to the axis of a balance, will urge that balance agreeably to the same law: and if it did, it still does not follow that the oscillations of the balance will be isochronous; for the force has to move not only the balance but also the spring. Part of the restoring force of the spring is employed in restoring it rapidly to its quiescent shape, and thus enabling it to *follow and still impel* the yielding balance. It is therefore only the surplus which is employed in actually moving the balance, and it is uncertain whether this surplus varies according to the same law, being always the same proportion of the whole force of the spring. We find it an extremely difficult problem to determine the law of variation of this surplus, even in the simplest form of the spring; nay, it is by no means an easy problem to determine the law of oscillation of a spring, unloaded with any balance; and we can easily shew that there are such forms of a spring, that although the velocity with which the different parts approach to their quiescent position be exactly as their excursion from it, this is by no means the law of velocity which this spring will produce in a balance. The matter of fact is, that when the spring is a simple straight steel wire, suspending the balance in the direction of its axis, the motions of it, if not immoderate, are precisely agreeable to Huyghens's and Hooke's rule; and that the motion of a balance urged by a spring wound up into a flat, or a cylindrical spiral, as in common watches, and those of Arnold, deviates sensibly from it, unless a certain analogy be preserved between the length and the elasticity of the spring. If the spring be immoderately long, the wide vibrations are slower than the narrow ones; and the contrary is observed when the spring is immoderately short. A certain taper, or gradual diminution of the spring, is also found to have an effect in equalizing the wide and narrow vibrations. There is also a great difference between the force with which a part of the spring unbends itself, and the action of that force in urging the balance round its axis; and the performance of many watches, good in other respects, is often faulty from the manner in which this unbending force is employed.

But, since these corrections are in our power in a considerable degree, we may suppose them applied, and the true motion (which we shall call the cycloidal) attained; and we may then adapt the construction of the scapement to the preserving this motion undisturbed. And here we must see at once that the problem is incomparably more delicate than in the case of pendulums. The vibrations must be very wide, and the angular motion rapid, that it may be little affected by external motions. The smallest inequalities of maintaining power acting through so great a space, must bear a considerable proportion to the very minute momentum of a watch balance. Oil is as clammy on the pallets of a watch as on those of a clock; a viscidity which would never be felt by a pendulum of 20 pounds weight will stop a balance of 20 grains altogether. For the same reason, it is evident that any impropriety in the form of the pallet must be incomparably more pernicious than in the case of a pendulum; the deviation which this may occasion from a force proportional to the angular distance from the middle point, must bear a great proportion to the whole force.

The common recoiling scapement of the old clocks still holds its place in the ordinary pocket watches, and answers all the common purposes of a watch very well. A well finished watch, with a recoiling scapement will keep time within a minute in the day. This is enough for the ordinary affairs of life. But such watches are subject to great variation in their rate of going, by any change in the power of the wheels. This is evident; for if the watch be held back, or pressed forward, by the key applied to the fusee square, we hear the beating greatly retarded or accelerated. The maintaining power, in the best of such watches, is never less than one-fifth of the regulating power of the spring. For, if we take off the balance spring, and allow the balance to vibrate by the impulse of the wheels alone, we shall find the minute hand to go forward from 25 to 30 minutes per hour. Suppose it 30. Then, since the wheels act through equal spaces with or without a spring, the forces are as the squares of the acquired velocities. (DYNAMICS, *Suppl.* n° 95.) The velocity in this case is double; therefore the accelerating force is quadruple,

ruple, and the force of the fpring is three times that of the wheels. If the hand goes forward 25 minutes, the force of the wheels is about one-fifth of that of the fpring. This great proportion is neceffary, as already obferved, that the watch may go as foon as unftopped.

We have but little to fay on this fcapement; its principle and manner of action, and its good and bad qualities, being the fame with thofe of the fimilar fcapement for pendulums. It is evident that the maintaining power being applied in the moft direct manner, and during the whole of the vibration, it will have the greateft poffible influence to move the balance. A given mainfpring and train will keep in motion a heavier balance by means of this fcapement than by any other. But, on the other hand, and for the fame reafon, the balance has lefs dominion over the wheel work, and its vibrations are more affected by any irregularities of the wheelwork. Moreover, the chief action of the wheel being at the very extremities of the vibrations, and being very abrupt, the variations in its force are moft hurtful to the ifochronifm of the vibrations.

Although this fcapement is extremely fimple, it is fufceptible of more degrees of goodnefs or imperfection than almoft any other, by the variation of the few particulars of its conftruction. We fhall therefore briefly defcribe that conftruction which long experience has fanctioned as approaching near to the beft performance that can be obtained from the common fcapement. Fig. 11. reprefents it in what are thought its beft proportions, as it appears when looking ftraight down on the end of the balance arbor. C is the centre of the balance and verge. CA and CB are the two pallets; CA being the upper pallet, or the one next to the balance, and CB being the lower one. F and D are two teeth of the crown wheel, moving from left to right; and E, G, are two teeth on the lower part of the circumference, moving from right to left. The tooth D is reprefented as juft efcaped from the point of CA, and the lower tooth E as juft come in contact with the lower pallet. The fcapement fhould not, however, be quite fo clofe, becaufe an inequality on the teeth might prevent D from efcaping at all. For if E touch the pallet CB before D has quitted CA, all will ftand ftill. This fault will be corrected by withdrawing the wheel a little from the verge, or by fhortening the pallets.

The proportions are as follow. The diftance between the front of the teeth (that is, of G, F, E, D) and the axis C of the balance is one-fifth of FA, the diftance between the points of the teeth. The length CA, CB of the pallets is three-fifths of the fame diftance. The pallets make an angle ACB of 95 degrees, and the front DH or FK of the teeth make an angle of 25° with the axis of the crown-wheel. The floping fide of the tooth muft be of an epicycloidal form, fuited to the relative motion of the tooth and pallet.

From thefe proportions it appears that the pallet A can *throw out*, by the action of the tooth D, till it reaches *a*, 120 degrees from CL, the line of the crown-wheel axis. For it can throw out till the pallet B ftrike againft the front of E, which is inclined 25° to CL. To this add BCA, = 95°, and we have LC *a* = 120. In like manner B will throw out as far on the other fide. From 240, the fum of thefe angles, take the angle of the pallets 95°, and there remains 145° for the greateft vibration which the balance can make without ftriking the front of the teeth. This extent of vibration fuppofes the teeth to terminate in points, and the acting furfaces of the pallets to be planes directed to the very axis of the verge. But the points of the teeth muft be rounded off a little for ftrength, and to diminifh friction on the face of the pallets. This diminifhes the angle of fcapement very confiderably, by fhortening the teeth. Moreover, we muft by no means allow the point of the pallet to bank or ftrike on the forefide of a tooth. This would greatly derange the vibration by the violence and abruptnefs of the check which the wheel would give to the pallet. This circumftance makes it improper to continue the vibrations much beyond the angle of fcapement. One-third of a circle, or 120°, is therefore reckoned a very proper vibration for a fcapement made in thefe proportions. The impulfe of the wheels, or the angle of fcapement, may be increafed by making the face of the pallets a little concave (preferving the fame angle at the centre). The vibration may alfo be widened by pufhing the wheel nearer to the verge. This would alfo diminifh the recoil. Indeed this may be entirely removed by bringing the front of the wheel up to C, and making the face of the pallet not a radius, but parallel to a radius and behind it, *i. e.* by placing the pallet CA fo that its acting face may be where its back is juft now. In this cafe, the tooth D would droop on it at the centre, and lie there at reft, while the balance completes its vibration. But this would make the banking (as the ftroke is called) on the teeth almoft unavoidable. In fhort, after varying every circumftance in every poffible manner, the beft makers have fettled on a fcapement very nearly fuch as we have defcribed. Precife rules can fcarcely be given; becaufe the law by which the force acting on the pallets varies in its intenfity, deviates fo widely from the action of the balance fpring, efpecially near the limits of the excurfions.

The difcoveries of Huyghens and Newton in rational mechanics engaged all the mathematical philofophers of Europe in the folution of mechanical problems, about the end of the laft century. The vibrations of elaftic plates or wires, and their influence on watch balances, became familiar to every body. The great requifites for producing ifochronous vibrations were well underftood, and the artifts were prompted by the fpeculatifts to attempt conftructions of fcapements proper for this purpofe. It appeared clearly, that the moft effectual means for this purpofe was to leave the balance unconnected with the wheels, efpecially near the extremities of the vibration, where the motion is languid, and where every inequality of maintaining power muft act for a longer time, and therefore have a great effect on the whole duration of the vibrations. The maxim of conftruction that naturally arifes from thefe reflections is to *confine*, if poffible, *the action of the wheels to the middle of the vibration*, where the motion is rapid, and where the chief effect of an increafe or diminution of the maintaining power will be to enlarge or contract the angular motions, but will make little change on their duration; becaufe the greateft part of the motion will be effected by the balance fpring alone. This maxim was inculcated in exprefs terms by John Bernoulli, in his *Recherches Mechaniques et Phyfiques*; but it had been fuggefted by common fenfe to feveral unletterred artifts before that time. About the beginning of the 18th century watches

watches were made in London, where the verge had a portion edb (fig. 12.) of a ſmall cylinder, having its centre c in the axis, and a radial pallet $b\ a$ proceeding from it. Suppoſe a tooth juſt eſcaped from the point of the pallet, moving in the direction bde, the cylindrical part was ſo ſituated that the next tooth dropped on it at a ſmall diſtance from its termination. While the verge continues turning in the direction bdc, the tooth continues reſting on the cylinder, and the balance ſuſtains no *action* from the wheels, and has only to overcome the minute frictions on the poliſhed ſurface of a hard ſteel cylinder. This motion may perhaps continue till the pallet acquires the poſition f, almoſt touching the tooth. It then ſtops, its motion being extinguiſhed by the increaſing force of the ſpring. It now returns, moving in the direction edb; and when the pallet has acquired the poſition $c\,i$, the tooth g quits the circumference of the cylinder, and drops in on the pallet at the very centre. The crooked form of the tooth allows the pallet to proceed ſtill farther, before there is any danger of banking on the tooth. This vibration being alſo ended, the balance reſumes its firſt direction, and the tooth now acts on the face of the pallet, and reſtores to the balance all the motion which it had loſt by friction, &c. during the two preceeding vibrations.

It is evident that this conſtruction obviates all the objections to the former recoiling ſcapement, and that, by ſufficiently diminiſhing the diameter of the cylindrical part, the friction may be reduced to a very ſmall quantity, and the balance be made to move by the action of the ſpring during the whole of the excurſion, and of the returning vibration. Yet this conſtruction does not ſeem to have come much into uſe, owing, in all probability, to the great difficulty of making the drop ſo accurate in all the teeth. The ſmalleſt inequality in the length of a tooth would occaſion it to drop ſooner or later; and if the cylinder was made very ſmall, to diminiſh friction, the formation of the notch was almoſt a microſcopical operation, and the ſmalleſt ſhake in the axis of the verge or the balance-wheel would make the tooth ſlip paſt the cylinder, and the watch run down amain.

About the ſame time, a French artiſt in London (then the ſchool of this art) formed another ſcapement, with the ſame views. We have not any diſtinct account of it; but are only informed (in the 7th volume of the *Machines approuvées par l'Acad. des Sciences*) that the tooth reſted on the ſurface of a hollow cylinder, and then eſcaped by acting on the inclined edge of it. But we may preſume that it had merit, being there told that Sir Iſaac Newton wore a watch of this kind.

A much ſuperior ſcapement, on the ſame principle, was invented by Mr Geo. Graham, at the ſame time that he changed the recoiling ſcapement for pendulums into the dead beat. Indeed it is the ſame ſcapement, accommodated to the large vibrations of a balance. In fig. 13. DE repreſents part of the rim of the balance-wheel, A and C are two of its teeth, having their faces $b\,e$ formed into planes, inclined to the circumference of the wheel, in an angle of about 15 degrees; ſo that the length $b\,e$ of the face is nearly quadruple of its height $e\,m$. Suppoſe a circular arch ABC deſcribed round the centre of the wheel, and through the middle of the faces of the teeth. The axis of the balance paſſes through ſome point B of this arch, and we may ſay that the mean circumference of the teeth paſſes through the centre of the verge. On this axis is fixed a portion of a thin hollow cylinder bcd, made of hard tempered ſteel, or of ſome hard and tough ſtone, ſuch as ruby or ſapphire. Agates, though very hard, are brittle. Chalcedony and cornelian are tough, but inferior in hardneſs. This cylinder is ſo placed on the verge, that when the balance is in its quieſcent poſition, the two edges b and d are in the circumference which paſſes through the points of the teeth. By this conſtruction the portion of the cylinder will occupy 210° of the circumference, or 30° more than a ſemicircle. The edge b, to which the tooth approaches from without, is rounded off on both angles. The other edge d is formed into a plane, inclined to the radius about 30°.

Now, ſuppoſe the wheel preſſed forward in the direction AC. The point b of the tooth, touching the rounded edge, will puſh it outwards, turning the balance round in the direction $b\,c\,d$. The heel e of the tooth will eſcape from this edge when it is in the poſition h, and e is in the poſition f. The point b of the tooth is now at d, but the edge of the cylinder has now got to i. The tooth, therefore, reſts on the inſide of the cylinder, while the balance continues its vibration a little way, in conſequence of the ſhove which it has received from the action of the inclined plane puſhing it out of the way, as the mould board of a plough ſhoves a ſtone aſide. When this vibration is ended, by the oppoſition of the balance-ſpring, the balance returns, the tooth (now in the poſition B) rubbing all the while on the inſide of the cylinder. The balance comes back into its natural poſition $b\,c\,d$, with an accelerated motion, by the action of its ſpring, and would, of itſelf, vibrate as far, at leaſt, on the other ſide. But it is aided again by the tooth, which, preſſing on the edge d, puſhes it aſide, till it come into the poſition k, when the tooth eſcapes from the cylinder altogether. At this moment the other edge of the cylinder is in the poſition l, and therefore is in the way of the next tooth, now in the poſition A. The balance continues its vibration, the tooth all the while reſting, and rubbing on the outſide of the cylinder. When this vibration, in the direction dcb, is finiſhed, the balance reſumes its firſt motion bcd, by the action of the ſpring, and the tooth begins to act on the firſt edge b, as ſoon as the balance gets into its natural poſition, ſhoves it aſide, eſcapes from it, and drops on the inſide of the cylinder. In this manner are the vibrations produced, gradually increaſed to their maximum, and maintained in that ſtate. Every ſucceeding tooth of the wheel acts firſt on the edge b, and then on the edge d; reſting firſt on the outſide, and then on the inſide of the cylinder. The balance is under the influence of the wheels while the edge b paſſes to h, and while d paſſes to k; and the reſt of the vibration is performed without any *action* on the part of the wheels, but is a little obſtructed by friction, and by the clammineſs of the oil. In the conſtruction now deſcribed, the arch of action or ſcapement is evidently 30°, being twice the angle which the face of a tooth makes with the circumference.

The reader will perceive, that when this ſcapement is executed in ſuch a manner that the ſucceeding tooth is in contact with the cylinder at the inſtant that the preceding one eſcapes from it, the face of the tooth muſt be equal to the inſide diameter of the cylinder, and that

that the diſtance between the heel of one tooth and the point of the following one muſt be equal to the outſide diameter. When the ſcapement is ſo cloſe there is no drop. A good artiſt approaches as near to this adjuſtment as poſſible; becauſe, while a tooth is dropping, but not yet in contact, it is not acting on the balance, and ſome force is loſt. The execution is accounted very good, if the diſtance between the centres of two teeth is twice the external diameter of the cylinder. This allows a drop equal to the thickneſs of the cylinder, which is about $\frac{1}{15}$th of its diameter.

We muſt alſo explain how this cylinder is ſo connected with the verge as to make ſuch a great revolution round the tooth of the wheel. The triangular tooth *e b m* is placed on the top of a little pillar or pin fixed into the extremity of the piece of braſs *m* D formed on the rim of the wheel. Thus the wedge-tooth has its plane parallel to the plane of the wheel, but at a ſmall diſtance above it. Fig. B repreſents the verge, a long hollow cylinder of hard ſteel. A great portion of the metal is cut out. If it were ſpread out flat, it would have the ſhape of Fig. C. Suppoſe this rolled up till the edges GH and G'H' are joined, and we have the exact form. The part acted on by the point of the tooth is the dotted line *b d*. The part DIFE' ſerves to connect the two ends. Thus it appears to be a very ſlender and delicate piece; but being of tempered ſteel, it is ſtrong enough to reſiſt moderate jolts. The ruby cylinders are much more delicate.

Such is the cylinder ſcapement of Mr Graham, called alſo the HORIZONTAL SCAPEMENT, becauſe the balance wheel is parallel to the others. Let us ſee how far it may be expected to anſwer the intended purpoſes. If the excurſions of the balance beyond the angle of impulſion were made altogether unconnected with the wheels, the *whole vibration* would be quicker than one of the ſame extent, made by the action of the balance-ſpring alone, becauſe the middle part of it is accelerated by the wheels. But the excurſions are obſtructed by friction and the clammineſs of oil. The effect of this in *obſtructing* the motion is very conſiderable. Mr Le Roy placed the balance ſo, that it reſted when the point of the tooth was on the middle of the cylindric ſurface. When the wheel was allowed to preſs on it, and it was drawn 80° from this poſition, it vibrated only during $4\frac{1}{2}$ ſeconds. When the wheel was not allowed to touch the cylinder, it vibrated 90 ſeconds, or 20 times as long; ſo much did the friction on the cylinder exceed that of the pivots. We are not ſufficiently acquainted with the laws of either of theſe obſtructions to pronounce decidedly whether they will increaſe or diminiſh the *time* of the whole vibrations. We obſerve diſtinctly, in motions with conſiderable friction, that it does not increaſe nearly ſo faſt as the velocity of the motion; nay, it is often leſs when the velocity is very great. In all caſes it is obſerved to terminate motions abruptly. The friction requires a certain force to overcome it, and if the body has any leſs it will ſtop. Now this will not only contract the excurſion of the balance, but will ſhorten the time. But the return to the angle of impulſion will undoubtedly be of longer duration than the excurſion; for the arch of return, from the extremity of the excurſion to its beginning, where the angle of impulſion ends, is the ſame with the arch of excurſion. The velocity which the balance has in any point of the return is leſs than what it had in the ſame point of the excurſion; becauſe, in the excurſion, it had velocity enough to carry it to the extremity, and alſo to overcome the friction. In the return, it could, even without friction, only have the velocity which would have carried it to the extremity; and this ſmaller velocity is diminiſhed by friction during the return. The velocity being leſs through the whole return than during the excurſion, the time muſt be greater. It may therefore happen that this retardation of the return may compenſate the contraction of the excurſion and the diminution of its duration. In this caſe the vibration will occupy the ſame time as if the balance had been free from the wheels. But it may more than compenſate, and the vibrations will then be ſlower; or it may not fully compenſate, and they will be quicker. We cannot therefore ſay *à priori*, which of the two will happen: but we may venture to ſay that an increaſe of the force of the wheels will make the watch go ſlower: for this will exert a greater preſſure, give a greater impulſion, produce a wider excurſion, and increaſe the friction during that greater excurſion, making the wide vibrations ſlower than the narrow ones: becauſe the angle of impulſion remaining the ſame, the preſſures exerted muſt be quadrupled, in order to double the excurſion (ſee DYNAMICS, n° 95. *Suppl.*), and therefore the friction will be increaſed in a greater proportion than the momentum which is to overcome it. But, with reſpect to the obſtruction ariſing from the viſcidity of the oil, we know that it follows a very different law. It bears a manifeſt relation to the velocity, and is nearly proportional to it. But ſtill it is difficult to ſay how this will affect the whole vibration. The duration of the excurſion will not be ſo much contracted as by an equal obſtruction from friction, becauſe it will not terminate the motion abruptly. There are therefore more chances of the increaſed duration of the return exceeding the diminution of it in the excurſion. All that we can ſay, therefore, is, that there will be a compenſation in both caſes. The time of excurſion will be contracted, and that of return augmented.

Now, as the friction may be greatly diminiſhed by fine poliſh, fine oil, and a ſmall diameter of the cylinder, we may reaſonably expect that the vibrations of ſuch a balance will not vary nearly ſo much from iſochroniſm as with a recoiling ſcapement, and will be little affected by changes in the force of the wheels. Accordingly, Graham's cylindrical ſcapement ſupplanted all others as ſoon as it was generally known. We cannot compare the vibrations with thoſe of a free balance, becauſe we have no way of making a free balance vibrate for ſome hours. But we find that doubling or trebling the force of the wheels makes very little alteration in the rate of the watch, though it greatly enlarges the angular motion. Any one may perceive the immenſe ſuperiority of this ſcapement over the common recoiling ſcapement, by preſſing forward the movement of a horizontal watch with the key, or by keeping it back. No great change can be obſerved in the frequency of the beats, however hard we preſs. But a more careful examination ſhews that an increaſe of the power of the wheels generally cauſes the watch to go ſlower; and that this is more remarkable as the watch has been long going without being cleaned. This ſhews that the cauſe is to be aſcribed to the friction and oil operating

operating on the wide arches of excurſion. But when this ſcapement is well executed, in the beſt proportions of the parts, the performance is extremely good. We know ſuch watches, which have continued for ſeveral weeks without ever varying more than 7″ in one day from equable motion. We have ſeen one whoſe cylinder was not concentric with the balance, but ſo placed on the verge that the axis of the verge was at *o* (fig. 13.), between the centre B of the cylinder and the entering edge *b*, and B*e* was equal to the thickneſs of the cylinder. The watch was made by Emery of London, and was ſaid to go with aſtoniſhing regularity, ſo as to equal any time piece while the temperature of the air did not vary; and when clean, was ſaid to be leſs affected by the temperature than a watch with a free ſcapement, but unprovided with a compenſation piece. It is evident that this watch muſt have a minute recoil. This was ſaid to be the aim of the artiſt, in order to compenſate for the obſtruction cauſed by friction during the return of the balance from its excurſions. It indeed promiſes to have this effect; but we ſhould fear that it ſubjects the excurſions to the influence of the wheels. We ſuſpect that the indifferent performance of cylinder watches may often ariſe from the cylinder being off the centre in ſome diſadvantageous manner.

The watch from which the proportions here ſtated were taken, is a very fine one made by Graham for Archibald Duke of Argyle, which has kept time with the regularity now mentioned. We believe that there are but few watches which have ſo large a portion of the cylinder: few indeed have more than one half, or 180° of the circumference. But this is too little. The tooth of the wheel does not begin to act on the reſting cylinder till its middle point A or B touch one of the edges. To obtain the ſame angle of ſcapement, the inclination of the face of the tooth muſt be increaſed (it muſt be doubled); and this requires the maintaining power to be increaſed in the ſame proportion. Beſides, in ſuch a ſcapement it may happen that the tooth will never reſt on the cylinder; becauſe the inſtant that it quits one edge it falls on the other, and puſhes it aſide, ſo that the balance acquires no wider vibration than the angle of ſcapement, and is continually under the influence of the wheels. The ſcapement is in its beſt ſtate when the portion of the cylinder exceeds 180° by twice the inclination of the teeth to the circumference of the wheel.

It would employ volumes to deſcribe all the ſcapements which have been contrived by different artiſts, aiming at the ſame points which Graham had in view. We ſhall only take notice of ſuch as have ſome eſſential difference in principle.

Fig. 14. repreſents a ſcapement invented in France, and called the *Echappement à Virgule*, becauſe the pallet reſembles a comma. The teeth A, B, C, of the balance wheel are ſet very oblique to the radius, and there is formed on the point of each a pin, ſtanding up perpendicular to the plane of the wheel. This greatly reſembles the wheel of Graham's ſcapement, when the triangular wedge is cut off from the top of the pin on which it ſtands. The axis *c* of the verge is placed in the circumference paſſing through the pins. The pallet is a plate of hard ſteel *aefdb*, having its plane parallel to the plane of the wheel. The inner edge of this plate is formed into a concave cylindrical ſurface between *o* and *b*, whoſe axis *c* coincides with the axis of the verge. Adjoining to this is the acting face *bd* of the pallet. This is either a ſtraight line *bd*, making an angle of nearly 30° with a line *cbg* drawn from the centre, or it is more generally curved, according to the noſtrum of the artiſt. The back of the pallet *aef* is alſo a cylindrical ſurface (convex) concentric with the other. This extends about 100° from *a* to *f*. The part between *f* and *d* may have any ſhape. The interval *ao* is formed into a convex ſurface, in ſuch a manner as to be everywhere interſected by the radius in an angle of 30° nearly; *i. e.* it is a portion of an equiangular ſpiral. The whole of this is connected with the verge by a crank, which paſſes perpendicularly through it between *f* and *e*; and the plate is ſet at ſuch height on the crank or verge, that it can turn round clear of the wheel, but not clear of the pins. The teeth of the wheel are ſet ſo obliquely, and made ſo ſlender, that the verge may turn almoſt quite round without the crank's banking on the teeth. The part *fdb*, called the horn, is of ſuch a length, that when one pin B reſts on the outſide cylinder at *a*, the point *d* is juſt clear of the next pin A.

When the wheel is not acting, and the balance ſpring is in equilibrio, the poſition of the balance is ſuch that the point *d* of the horn is near *i*, about 30° from *d*. The figure repreſents it in the poſition which it has when the tooth A has juſt eſcaped from the point *d* of the horn. In this poſition the next tooth B is applied to the convex cylinder, a very little way (about 5°) from its extremity *a*. This deſcription will enable the reader to underſtand the operation of the virgule ſcapement.

Now ſuppoſe the pin A juſt eſcaped from the horn. The ſucceeding pin B is now in contact with the back of the cylinder; and the balance, having got an impulſe by the action of A along the concave pallet *bd*, continues its motion in the direction *dgh*, till its force is ſpent, the point of the horn arriving perhaps at *h*, more than 90° from *d*. All this while the following tooth B is reſting on the back *ef* of the cylinder. The balance now returns, by the action of its ſpring; and when the horn is at *i*, the pin gets over the edge *ao*, and drops on the oppoſite ſide of the concave cylinder, where it reſts, while the horn moves from *i* to *k*, where it ſtops, the force of the balance being again ſpent. The balance then returns; and when the horn comes within 30° of *d*, the pin gets out of the hollow cylinder, ſhoves the horn out of its way, and eſcapes at *d*. Beſides the impulſe which the balance receives by the action of the wheel on the horn *bd*, there is another, though ſmaller, action in the contrary direction, while the point of B paſſes over the ſurface *ao*; for this ſurface being inclined to the radius, the preſſure on it urges the balance round in the direction *hdi*.

The chief difference of this ſcapement from the former is that the inclined plane is taken from the teeth of the wheel, and placed on the verge. This alone is a conſiderable improvement; for it is difficult to ſhape all the teeth alike; whereas the horn *bd* is invariable. Moreover, the reſting parts, although they be drawn large in this figure for the ſake of diſtinctneſs, may be made vaſtly ſmaller than Graham's cylinder, which muſt be big enough to hold a tooth within it. By this change, the friction, during the repoſe of the wheel, that

that is, during the excursions of the balance, may be vastly diminished. The inside cylinder need be no bigger than to receive the pin. But although the performance of these scapements is excellent, they have not come into general use in this country. The cause seems to be the great nicety requisite in making the pins of the wheel pass exactly through the axis of the verge. The least shake in the pivots of the balance and balance-wheel must greatly change the action. A very minute increase of distance between the pivots will cause the pin B to slide from the edge *a* to the horn, without resting at all on the inside cylinder; and when it does so, it will stop the balance at once, and, immediately after, the watch will run down. The same irregularities will happen if all the pins be not at precisely the same distance from the axis of the wheel.

This scapement was greatly improved, and, in appearance, totally changed, by Mr Lepaute of Paris in 1753. By placing the pins alternately on the two sides of the rim of the balance-wheel, he avoided the use of the outside cylinder altogether. The scapement is of such a singular form, that it is not easy to represent it by any drawing. We shall endeavour, however, to describe it in such a manner as that our readers, who are not artists, will understand its manner of acting. Artists by profession will easily comprehend how the parts may be united which we represent as separate.

Let ABC (fig. 15.) represent part of the rim of the balance-wheel, having the pins 1, 2, 3, 4, 5, &c. projecting from its faces; the pins 1, 3, 5, being on the side next the eye, but the pins 2 and 4 on the farther side. D is the centre of the balance and verge, and the small circle round D represents its thickness. But the verge in this place is crooked, like a crank, that the rim of the wheel may not be interrupted by it. This will be more particularly described by and bye. There is attached to it a piece of hard tempered steel *abcd*, of which the part *abc* is a concave arch of a circle, having D for its centre. It wants about 30° of a semicircle. The rest of it *cd* is also an arch of a circle, having the same radius with the balance-wheel. The natural position of the balance is such, that a line drawn from D, through the middle of the face *cd*, is a tangent to the circumference of the wheel. But, suppose the balance turned round till the point *d* of the horn comes to *d'*, and the point *c* comes to 2, in the circumference in which the pins are placed. Then the pin, pressing on the beginning of the horn or pallet, pushes it aside, slides along it, and escapes at *d*, after having generated a certain velocity in the balance. So far this scapement is like the virgule scapement described already. But now let another pallet, similar to the one now described, be placed on the other side of the wheel, but in a contrary position, with the acting face of the pallet turned away from the centre of the wheel. Let it be so placed at E, that the moment that the pin 1, on the upper side of the wheel, escapes from the pallet *cd*, the pin 4, on the under side of the wheel, falls on the end of the circular arch *efg* of the other pallet. Let the two pallets be connected by means of equal pulleys G and F on the axis of each, and a thread round both, so that they shall turn one way. The balance on the axis D, having gotten an impulse from the action of the pin 1, will continue its motion from A towards *i*, and will carry the other pallet with a similar motion round the centre E from *h* towards *k*. The pin 4 will therefore rest on the concave arch *gfe* as the pallet turns round. When the force of the balance is spent, the pallet *cd* returns towards its first position. The pallet *gh* turns along with it; and when the point of the first has arrived at *d*, the beginning *g* of the other arrives at the pin 4; and, proceeding a little farther, this pin escapes from the concave arch *efg*, and slides along the pallet *gh*, pushing it aside, and therefore urging the pallet round the centre E, and consequently (by means of the connection of the pulleys) urging the balance on the axis D round at the same time, and in the same direction. The pin 4 escapes from the pallet *gh*, when *h* arrives at 3; but in the time that the pin 4 was sliding along the yielding pallet *gh*, the pin 3 is moving in the circumference BDA; and the instant that the pin 4 escapes from *h* at 3, the pin 3 arrives at 2, and finds the beginning *c* of the concave arch *cba* ready to receive it. It therefore rests on this arch, while the balance continues its motion. This perhaps continues till the point *b* of the arch comes to 2. The balance now stops, its force being spent, and then returns; and the pin 3 escapes from the circle at *c*, slides along the yielding pallet *cd*, and when it escapes at 1, another pin on the under side of the wheel arrives at 4, and finds the arch *gfe* ready to receive it. And in this manner will the vibration of the balance be continued.

This description of the mode of action at the same time points out the dimensions which must be given to the parts of the pallet. The length of the pallet *cd* or *gh* must be equal to the interval between two succeeding pins, and the distance of the centres D and E must be double of this. The radius D*e* or E*g* may be as small as we please. The concave arches *cba* and *gfe* must be continued far enough to keep a pin resting on them during the whole excursion of the balance. The angle of scapement, in which the balance is under the influence of the wheels, is had by drawing D*c* and D*d*. This angle *c*D*d* is about 30°, but may be made greater or less.

Fig. B will give some notion how the two pallets may be combined on one verge. KL represents the verge with a pivot at each end. It is bent into a crank MNO, to admit the balance wheel between its branches. BC represents this wheel, seen edgewise, with its pins, alternately on different sides. The pallets are also represented edgewise by *bcd* and *hgf*, fixed to the inside of the branches of the crank, fronting each other. The position of their acting faces may be seen in the preceding figure, on the verge D, where the pallet *gh* is represented by the dotted line 2 *i*, as being situated behind the pallet *cd*. The remote pallet 2 *i* is placed so, that when the point *d* of the near pallet is just quitted by a pin 1 on the upper side of the wheel, the angle formed by the face and the arch of rest of the other pallet is just ready to receive the next pin 2, which lies on the under side of the rim. A little attention will make it plain, that the action will be precisely the same as when the pallets were on separate axes. The pin 1 escapes from *d*, and the pin 2 is received on the arch of rest, and locks the wheel while the balance is continuing its motion. When it returns, 2 gets off the arch of rest, pushes aside the pallet 2 *i*, escapes from it when *i* gets to 1, and then the pin 3 finds the point *c* ready

Watch-work.

ready to receive it, &c. The vibrations may be increafed by giving a fufficient impulfe through the angle of fcapement. But they cannot be more than a certain quantity, otherwife the top N of the crank will ftrike the rim of the wheel. By placing the pins at the very edge of the wheel, the vibrations may eafily be increafed to a femicircle. By placing them at the points of long teeth, the crank may get in between them, and the vibrations extended ftill farther, perhaps to 240°.

This fcapement is unqueftionably a very good one; and when equally well executed, fhould excel Graham's, both by having but two acting faces to form (and thefe of hard fteel or of ftone), and by allowing us to make the circle of reft exceedingly fmall without diminifhing the acting face of the pallet. This will greatly diminifh the friction and the influence of oil. But, on the other hand, we apprehend that it is of very difficult execution. The figure of the pallets, in a manner that fhall be fufceptible of adjuftment and removal for repair, and yet fufficiently accurate and fteady, feems to us a very delicate j b.

Mr Cumming, in his Elements of Clock and Watchwork defcribes (flightly) pallets of the very fame conftruction, making what he conceives to be confiderable improvements in the form of the acting faces and the curves of reft. He has alfo made fome watches with this fcapement; but they were fo difficult, that few workmen can be found fit for the tafk; and they are exceedingly delicate, and apt to be put out of order. The connection of the pallets with each other, and with the verge, makes the whole fuch a contorted figure, that it is eafily bent and twifted by any jolt or unfkilful handling.

There remains another fcapement of this kind, having the tooth of the balance-wheel refting on a cylindrical furface on the axis of the verge during the excurfions of the balance beyond the angle of fcapement, and which differs fomewhat in the application of the maintaining power from all thofe already defcribed.

This is known by the name of *Dupleix's fcapement*, and is as follows: Fig. 16. reprefents the effential parts greatly magnified. AD is a portion of the balance-wheel, having teeth *f*, *b*, *g*, at the circumference. Thefe teeth are entirely for producing the *reft* of the wheel, while the balance is making excurfions beyond the fcapement. This is effected by means of an agate cylinder *o p q*, on the verge. This cylinder has a notch *o*. When the cylinder turns round in the direction *o p q*, the notch eafily paffes the tooth B which is refting on the cylindric furface; but when it returns in the direction *q p o*, the tooth B gets into the notch, and follows it, preffing on one fide of it till the notch comes into the pofition *o*. The tooth being then in the pofition *b*, efcapes from the notch, and another tooth drops on the convex furface of the cylinder at B.

The balance wheel is alfo furnifhed with a fet of ftout flat-fided pins, ftanding upright on its rim, as reprefented by *a*, D. There is alfo fixed on the verge a larger cylinder GFC above the fmaller one *o p q*, with its under furface clear of the wheel, and having a pallet C, of ruby or fapphire, firmly indented into it, and projecting fo far as juft to keep clear of the pins on the wheel. The pofition of this cylinder, with refpect to the fmaller one below it, is fuch that, when the tooth *b* is efcaped from the notch, the pallet C has juft paffed the pin *a*, which was at A while B refted on the fmall cylinder: but it moved from A to *a*, while B moved to *b*. The wheel being now at liberty, the pin *a* exerts its preffure on the pallet C in the moft direct and advantageous manner, and gives it a ftrong impulfion, following and accelerating it till another tooth ftops on the little cylinder. The angle of fcapement depends partly on the projection of the pallet, and partly on the diameter of the fmall cylinder and the advance of the tooth B into the notch. Independent of the action on the fmall cylinder, the angle of fcapement would be the whole arch of the large cylinder between C and *x*. But *a* ftops before it is clear of the pallet, and the arch of impulfion is fhortened by all the fpace that is defcribed by the pin while a tooth moves from B to *b*. It ftops at *a'*.

We are informed by the beft artifts, that this fcapement gives great fatisfaction, and equals, if it do not excel, Graham's cylindrical fcapement. It is eafier made, and requires very little oil on the fmall cylinder, and none at all on the pallet. They fay that it is the beft for pocket watches, and is coming every day more into repute. Theory feems to accord with this character. The refting cylinder may be made very fmall, and the direct impulfe on the pallet gives it a great fuperiority over all thofe already defcribed, where the action on the pallet is oblique, and therefore much force is loft by the influence of oil. But we fear that much force is loft by the tooth B fhifting its place, and thus fhortening the arch of impulfion; for we cannot reckon much on the action of B on the fide of the notch, becaufe the lever is fo extremely fhort. Accordingly, all the watches which we have feen of this kind have a very ftrong main fpring in proportion to the fize and vibration of the balance. If we leffen this diminution of the angle of impulfion, by leffening the cylinder *o p q*, and by not allowing B to penetrate far into the notch, the fmalleft inequality of the teeth, or fhake in the pivots of the balance or wheel, will caufe irregularity, and even uncertainties in the locking and unlocking the wheel by this cylinder.

A fcapement exceedingly like this was applied long ago by Dutertre, a French artift, to a pendulum. The only difference is, that in the pendulum fcapement the fmall cylinder is cut through to the centre, half of it only being left; but the pendulum fcapement gives a more effective employment of the maintaining power, becaufe the wheel acts on the pallet during the *whole* of the affifted vibration. In a balance fcapement, if we attempt to diminifh the inefficient motion of the pin from A to *a*, by leffening the diameter of the fmall cylinder, the hold given to the tooth in the notch will be fo trifling, that the tooth will be thrown out by the fmalleft play in the pivot holes, or inequality in the length of the teeth.

With this we conclude our account of fcapements, where the action of the maintaining power on the balance is fufpended during the excurfion beyond the angle of impulfion, by making a tooth reft on the furface of a fmall concentric cylinder. In fuch fcapements, the balance, during its excurfions, is almoft free from any connection with the wheels, and its ifochronifm is difturbed by nothing but the friction on this furface.—We come now to fcapements of more artful conftruction, in which the balance is really and completely free during

during the whole of its excurſion, being altogether diſengaged from the wheelwork. Theſe are called DETACHED SCAPEMENTS. They are of more recent date. We believe that Mr Le Roi was the firſt inventor of them, about the year 1748. In the Memoirs of the Academy of Paris for that year, and in the Collection of approved Machines and Inventions, we have deſcriptions of the contrivance. The balance-wheel reſts on a detent, while the balance is vibrating in perfect freedom. It has a pallet ſtanding out from the centre, which, in the courſe of vibration, paſſes cloſe by the point of a tooth of the wheel. At that inſtant a pin, connected with this pallet, withdraws the detent from the wheel, and the tooth juſt now mentioned follows the pallet with rapidity, and gives it a ſmart puſh forward. Immediately after, another tooth of the wheel meets the other claw of the detent, and the wheel is again locked. When the balance returns, the pin puſhes the detent back into its former place, where it again locks the wheel. Then the balance, reſuming its firſt direction, unlocks the wheel, and receives another impulſion from it. Thus the balance is unconnected with the wheels, except while it gets the impulſion, and at the moments of unlocking the wheels.

This contrivance has been reduced to the greateſt poſſible ſimplicity by the Britiſh artiſts, and ſeems ſcarcely capable of farther improvement. The following is one of the moſt approved conſtructions. In fig. 17. *a b c* repreſents the pallet, which is a cylinder of hard ſteel or ſtone, having a notch *a b*. A portion of the balance-wheel is repreſented by AB. It is placed ſo near to the cylinder that the cylinder is no more than clear of *two adjoining* teeth. DE is a long ſpring, ſo fixed to the watch-plate at E, as to preſs very gently on the ſtop pin G. A ſmall ſtud F is fixed to that ſide of the ſpring that is next to the wheel. The tooth of the wheel reſts on this ſtud, in ſuch a manner that the tooth *a* is juſt about to touch the cylinder, and the tooth *f* is juſt clear of it. Another ſpring, extremely ſlender, is attached to the ſpring DE, on the ſide next the balance-wheel, and claps cloſe to it, but keeping clear of the ſtud F, and having its point *o* projecting about $\frac{1}{50}$th of an inch beyond its extremity. When the point *o* is preſſed towards the wheel, it yields moſt readily; but, when preſſed in the oppoſite direction, it carries the ſpring DE along with it. The cylinder being ſo placed on the verge that the edge *a* of the notch is cloſe by the tooth *a*, a hole is drilled at *i*, cloſe by the projecting point of the ſlender ſpring, and a ſmall pin is driven into this hole. This is the whole apparatus; and this ſituation of the parts correſponds to the quieſcent poſition of the balance.

Now, let the balance be turned out of this poſition 80 or 90 degrees, in the direction *a b c*. When it is let go, it returns to this poſition with an accelerated motion. The pin *i* ſtrikes on the projecting point of the ſlender ſpring, and, preſſing the ſtrong ſpring DE outward from the wheel, withdraws the ſtud F from the tooth; and thus unlocks the wheel. The tooth *a* engages in the notch, and urges round the balance. The pin *i* quits the ſlender ſpring before the tooth quits the notch; ſo that when it is clear of the pallet, the wheel is locked again on the ſtud F, and another tooth *g* is now in the place of *a*, ready to act in the ſame manner. When the force of the balance is ſpent, it ſtops, and then returns toward its quieſcent poſition with a motion continually accelerated. The pin *i* arrives at the point *o* of the ſlender ſpring, raiſes it from the ſtrong ſpring without diſturbing the latter, and almoſt without *being* diſturbed by this trifling obſtacle; and it goes on, turning in the direction *a b c*, till its force is again ſpent; it ſtops, returns, again unlocks the wheel, and gets a new impulſion. And in this manner the vibrations are continued. Thus we ſee a vibration, almoſt free, maintained in a manner even more ſimple than the common crutch ſcapement. The impulſe is given direct, without any decompoſition by oblique action, and it is continued through the *whole* motion of the wheel. No part of this motion is loſt, as in Dupleix's ſcapement, by the *gradual* approach of the tooth to its active poſition. Very little force is required for unlocking the wheel, becauſe the ſpring DFE is made ſlender at the remote end E, ſo that it turns round E almoſt like a lever turning on pivots. A ſudden twitch of the watch, in the direction *b a*, might chance to unlock the wheel. But this will only derange one vibration, and even that not conſiderably, becauſe the teeth are ſo cloſe to the cylinder that the wheel cannot advance till the notch comes round to the place of ſcapement. A tooth will continue preſſing on the cylinder, and by its friction will change a little the extent and duration of a ſingle vibration. The greateſt derangement will happen if the wheel ſhould thus unlock by a jolt, while the notch paſſes through the arch of ſcapement in the returning vibration. Even this will not greatly derange it, when the watch is clean and vibrating wide; becauſe, in this poſition, the balance has its greateſt momentum, and the direction of the only jolt that can unlock the wheel tends to increaſe this momentum relatively. In ſhort, conſidering it theoretically, it ſeems an almoſt perfect ſcapement; and the performance of many of theſe watches abundantly confirms that opinion. They are known to keep time for many days together, without varying one ſecond from day to day; and this even under conſiderable variations of the maintaining power. Other detached ſcapements may equal this, but we ſcarcely expect any to exceed it; and its ſimplicity is ſo much ſuperior to any that we have ſeen, that, on this account, we are diſpoſed to give it the preference. We do not mean to ſay that it is the beſt for a pocket watch. Perhaps the ſcapement of Dupleix or Graham may be preferable, as being ſuſceptible of greater ſtrength, and more able to withſtand jolts. Yet it is a fact that ſome of the watches made in this form by Arnold and others have kept time in the wonderful manner abovementioned while carried about in the pocket.

Mr Mudge of London invented, about the year 1763, another detached ſcapement, of a ſtill more ingenious conſtruction. It is a counterpart of Mr Cumming's ſcapement for pendulums. The contrivance is to this effect. In fig. 18. *a b c* repreſents the balance. Its axis is bent into a large crank EFGHIK, ſufficiently roomy to admit within it two other axes M and L, with the proper cocks for receiving their pivots. The three axes form one ſtraight line. About theſe ſmaller axes are coiled two auxiliary ſprings, in oppoſite directions, having their outer extremities fixed in the ſtuds A and B. The balance has its ſpring alſo, as uſual, and the three ſprings are ſo diſpoſed that each of them

Fig 11

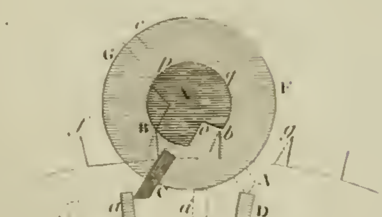

Fig 18

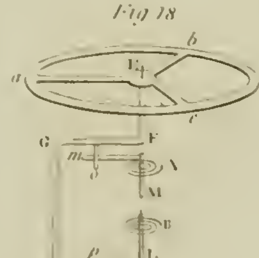

them alone would keep the balance at reſt in the ſame poſition, which we may ſuppoſe to be that repreſented in the figure. The auxiliary ſprings A and B are connected with the balance only occaſionally, by means of the arms *m* and *n* projecting from their reſpective axes. Theſe arms are catched on oppoſite ſides by the pins *o*, *p*, in the branches of the crank; ſo that when the balance turns round, it carries one or other of thoſe arms round with it, and, during this motion, it is affected by the auxiliary ſpring connected with the arm ſo carried round by it.

Let us ſuppoſe that the balance vibrates 120° on each ſide of its quieſcent poſition *a b c*, ſo that the radius E *a* acquires alternately, the poſitions E *b* and E *c*. The auxiliary ſprings are connected with the wheels by a common dead-beat pendulum ſcapement, ſo that each can be ſeparately wound up about 30°, and retained in that poſition. Let us alſo ſuppoſe that the ſpring A has been wound up 30° in the direction *a b*, by the wheel-work, and that the point *a* of the rim of the balance, having come from *c*, is paſſing through *a* with its greateſt velocity. When the radius E *a* has paſſed *a* 30° in its courſe toward *b*, the pin *o* finds the arm *m* in its way, and carries it along with it till *a* gets to *b*. But, by carrying away the arm *m*, it has unlocked the wheel-work, and the ſpring B is now wound up 30° in the other direction, but has no connection with the balance during this operation. Thus the balance finiſhes its ſemivibration *a b* of 120°, oppoſed by its own ſpring the whole way, and by the auxiliary ſpring A through an angle of 90°. It returns to the poſition E *a*, aided by A and by the balance ſpring, through an angle of 120°. In like manner, when E *a* has moved 30° toward the poſition E *c*, the pin *p* meets with the arm *n*, and carries it along with it through an angle of 90, oppoſed by the ſpring B, and then returns to the poſition E *a*, aſſiſted by the ſame ſpring through an arch of 120°.

Thus it appears that the balance is oppoſed by each auxiliary ſpring through an angle of 90°, and aſſiſted through an angle of 120°. This difference of action maintains the vibrations, and the neceſſary winding up of the auxiliary ſprings is performed by the wheel-work, at a time when they are totally diſengaged from the balance. No irregularity of the wheel-work can have any influence on the force of the auxiliary ſprings, and therefore the balance is completely diſengaged from all theſe irregularities, except in the ſhort moment of unlocking the wheel that winds up the ſprings.

This is a moſt ingenious conſtruction, and the neareſt approach to a free vibration that has yet been thought of. It deſerves particular remark that during the whole of the returning or accelerated ſemivibration, the united force of the ſprings is proportional to the diſtance from the quieſcent poſition. The ſame may be ſaid of the retarded excurſion beyond the angle of impulſe: therefore the only deviation of the forces from the law of cycloidal vibration is during the motion from the quieſcent poſition to the meeting with the auxiliary ſpring. Therefore, as the forces, on both ſides, beyond this angle, are in their due proportion, and the balance always makes ſuch excurſions, there ſeems nothing to diſturb the iſochroniſm, whether the vibrations are wide or narrow. Accordingly, the performance of this ſcapement, under the ſevereſt trials, equalled any that were compared with it, in as far as it depended on ſcapement alone. But it is evident that the execution of this ſcapement, though moſt ſimple in principle, muſt always be vaſtly more difficult than the one deſcribed before. There is ſo little room, that the parts muſt be exceedingly ſmall, requiring the moſt accurate workmanſhip. We think that it may be greatly ſimplified, preſerving all its advantages, and that the parts may be made of more than twice their preſent ſize, with even leſs load on the balance from the inertia of matter. This improvement is now carrying into effect by a friend.

Still, however, we do not ſee that this ſcapement is, theoretically, ſuperior to the laſt. The irregularities of maintaining power affect that ſcapement only in the arch of impulſion, where the velocity is great, and the time of action very ſmall. Moreover, the chief effect of the irregularities is only to enlarge the excurſions; and in theſe the wheels have no concern.

Mr Mudge has alſo given another detached ſcapement, which he recommends for pocket watches, and executed entirely to his ſatiſfaction in one made for the Queen. A dead beat pendulum ſcapement is interpoſed, as in the laſt, between the wheels and the balance. The crutch EDF (fig. 19.) has a third arm DG, ſtanding outwards from the meeting of the other two, and of twice their length. This arm terminates in a fork AGB. The verge V has a pallet C, which, when all is at reſt, would ſtand between the points A, B of the fork. But the wheel, by its action on the pallet E, forces the fork into the poſition B *g b*, the point A of the fork being now where B was before, juſt touching the cylindrical ſurface of the verge. The ſcapement of the crutch EDF is not accurately a dead beat ſcapement, but has a very ſmall recoil beyond the angle of impulſion. By this circumſtance the branch A (now at B) is made to preſs moſt gently on the cylinder, and keeps the wheel locked, while the balance is going round in the direction BHA. The point A gets moving from A to B by means of a notch in the cylinder, which turns round at the ſame time by the action of the branch AG on the pallet C; but A does not touch the cylinder during this motion, the notch leaving free room for its paſſage. When the balance returns from its excurſion, the pallet C ſtrikes on the branch A (ſtill at B), and unlocks the wheel. This now acting on the crutch pallet F, cauſes the branch *b* of the fork to follow the pallet C, and give it a ſtrong impulſe in the direction in which it is then moving, cauſing the balance to make a ſemivibration in the direction AHB. The fork is now in the ſituation A *g a*, ſimilar to B *g b*, and the wheel is again locked on the crutch pallet E.

The intelligent reader will admit this to be a very ſteady and effective ſcapement. The lockage of the wheel is procured in a very ingenious manner; and the friction on the cylinder, neceſſary for effecting this, may be made as ſmall as we pleaſe, notwithſtanding a very ſtrong action of the wheel: For the preſſure of the fork on the cylinder depends entirely on the degree of recoil that is formed on the pallets E and F. *Preſſure* on the cylinder is not *indiſpenſably* neceſſary, and the crutch ſcapement might be a real dead beat. But a ſmall recoil, by keeping the fork in contact with the cylinder, gives the moſt perfect ſteadineſs to the motion. The ingenious inventor, a man of approved integrity and judgment, declares that her Majeſty's watch was the beſt pocket

pocket watch he had ever feen. We are not difpofed to queftion its excellency. We faw an experiment watch of this conftruction, made by a country artift, having a balance fo heavy as to vibrate only twice in a fecond. Every vibration was fenfibly beyond a turn and a half, or 540°. The artift affured us, that when its proper balance was in, vibrating fomewhat more than five times in a fecond, the vibrations even exceeded this. He had procured it this great mobility by fubftituting a roller with fine pivots in place of the fimple pallet of Mudge. This great extent of detached vibration is an unqueftionable excellence, and is peculiar to thofe two fcapements of this ingenious artift.

Very ingenious fcapements have been made by Ernfhaw, Howel, Hayley, and other Britifh artifts; and many by the artifts of Paris and Geneva. But we muft conclude the article, having defcribed all that have any difference in principle.

The fcapement having been brought to this degree of perfection, we have an opportunity of making experiments on the law of action of fprings, which has been too readily affumed. We think it eafy to demonftrate, that the figure of a fpring, which muft have a great extent of rapid motion, will have a confiderable influence on the force which it impreffes on a balance in *actual motion*. The accurate determination of this influence is not very difficult in fome fimple cafes. It is the greateft of all in the plane fpiral, and the leaft in the cylindrical; and in this laft form, it is fo much lefs as the diameter is lefs, the length of the fpring being the fame. By employing many turns, in order to have the fame ultimate force at the extremity of the excurfion, this influence is increafed. A particular length of fpring, therefore, will make it equal to a given quantity; and it may thus compenfate for a particular magnitude of friction, and other obftructions. This accounts for the obfervation of Le Roy, who found that every fpring, *when applied to a movement*, had a certain length, which made the wide and narrow vibrations ifochronous. His method of trial was fo judicious, that there can be no doubt of the juftnefs of his conclufion. His time-keeper had no fuzee; and when the laft revolution of the main wheel was going on, the vibrations were but of half the extent of thofe made during the firft revolution. Without minding the real rate of going, he only compared the duration of the firft and laft revolution of the minute hand. An artift of our acquaintance repeated thefe experiments, and with the fame refult: But, unfortunately, could derive little benefit from them; becaufe in one ftate of the oil, or with one balance, he found the lengths of the fame fpring, which produced ifochronous vibrations, were different from thofe which had this effect in another ftate of the oil, or with another balance. He alfo obferved another difference in the rate, arifing from a difference of pofition, according as XII, VI, III, or IX, was uppermoft; which difference plainly arifes from the fwagging of the fpring by its weight, and, in that ftate, acting as a pendulum. This unluckily put a ftop to his attempts to leffen this hurtful influence by employing a cylindrical fpiral of fmall diameter and great length.

WATEHOO, an ifland in the South Pacific Ocean; a beautiful fpot, about 6 miles long and 4 broad. N. lat. 20 1, W. long. 158 15.—*Morse*.

WATER-Blowing Machine, called in French *Soufflet d'eau* or *trompe*, is a machine which, by the action of falling water, fupplies air to a blaft furnace. It confifts of an upright pipe, through which a fhower of water is made to fall; and this fhower carries down with it a mafs of air, which is received beneath in a kind of tub, and conducted to the furnace by means of a pipe. The firft idea of fuch a machine was doubtlefs fuggefted by thofe local winds, which are always produced by natural falls of water over precipices, and in the mountains (fee page 577 of volume II.); but perhaps we are indebted for the firft accurate theory of it to Profeffor Venturi.

That philofopher in his experimental refearches concerning the lateral communication of motion in fluids, proves that the water-blowing machine affords air to the furnace, by the accelerating force of gravity and the lateral communication of motion combined together. He begins with an idea, which, he candidly acknowledges, did not efcape the penetration of Leonardo Da Vinci. Suppofe a number of equal balls to move in contact with each other along the horizontal line AB (Plate XLVI. fig. 1.). Imagine them to pafs with an uniform motion, at the rate of four balls in a fecond. Let us take BF, equal to 16 feet Englifh. During each fecond four balls will fall from B to F, and their refpective diftances in falling will be nearly BC = 1, CD, = 3, DE = 5, EF = 7. We have here a very evident reprefentation of the feparation, and fucceffive elongation, which the accelerating force of gravity produces between bodies which fall after each other.

The rain water flows out of gutters by a continued current; but during its fall it feparates into portions in the vertical direction, and ftrikes the pavement with diftinct blows. The water likewife divides, and is fcattered in the horizontal direction. The ftream which iffues out of the gutter may be one inch in diameter, and ftrike the pavement over the fpace of one foot. The air which exifts between the vertical and horizontal feparations of the water which falls, is impelled and carried downwards. Other air fucceeds laterally; and in this manner a current of air or wind is produced round the place ftruck by the water. Hence the following idea of a water-blowing machine:

Let BCDE (fig. 2.) reprefent a pipe, through which the water of a canal AB falls into the lower receiver MN. The fides of the tube have openings all round, through which the air freely enters to fupply what the water carries down in its fall. This mixture of water and air proceeds to ftrike a mafs of ftone Q; whence rebounding through the whole width of the receiver MN, the water feparates from the air, and falls to the bottom at XZ, whence it is difcharged into the lower channel or drain, by one or more openings TV. The air being lefs heavy than the water, occupies the upper part of the receiver; whence being urged through the upper pipe O, it is conveyed to the forge.

It has been fuppofed by fome eminent chemifts, that the air which paffes through the pipe O is furnifhed by the decompofition of water. To afcertain whether this be the cafe or not, our author formed a water-blowing engine of a fmall fize. The pipe BD was two inches in diameter, and four feet in height. When the water accurately filled the fection BC, and all the lateral

ral openings of the pipe BDEC were cloſed, the pipe O no longer offered any wind. It is therefore evident, that in the open pipes the whole of the wind comes from the atmoſphere, and no portion is afforded by the decompoſition of water. It remains, therefore, to determine the circumſtances proper to drive into the receiver MN the greateſt quantity of air, and to meaſure that quantity.

1. To obtain the greateſt effect from the acceleration of gravity, it is neceſſary that the water ſhould begin to fall at BC, (fig. 2.) with the leaſt poſſible velocity; and that the height of the water FB ſhould be no more than is neceſſary to fill the ſection BC. Our author ſuppoſes the vertical velocity of this ſection to be produced by an height or head equal to BC.

2. We do not yet know, by direct experiment, the diſtance to which the lateral communication of motion between water and air can extend itſelf; but we may admit with confidence, that it can take place in a ſection double that of the original ſection with which the water enters the pipe. Let us ſuppoſe the ſection of the pipe BDEC to be double the ſection of the water at BC; and, in order that the ſtream of fluid may extend and divide itſelf through the whole double ſection of the pipe, ſome bars, or a grate, are placed in BC, to diſtribute and ſcatter the water through the whole internal part of the pipe.

3. Since the air is required to move in the pipe O with a certain velocity, it muſt be compreſſed in the receiver. This compreſſion will be proportioned to the ſum of the accelerations, which ſhall have been deſtroyed in the inferior part KD of the pipe. Taking KD $= 1,5$ feet, we ſhall have a preſſure ſufficient to give the requiſite velocity in the pipe O. The ſides of the portion KD, as well as thoſe of the receiver MN, muſt be exactly cloſed in every part.

4. The lateral openings in the remaining part of the pipe BK may be ſo diſpoſed and multiplied, particularly at the upper part, that the air may have free acceſs within the tube. We will ſuppoſe them to be ſuch that 0,1 foot height of water might be ſufficient to give the neceſſary velocity to the air at its introduction through the apertures.

All theſe conditions being attended to, and ſuppoſing the pipe BD to be cylindrical, it is required to determine the quantity of air which paſſes in a given time through the circular ſection KL. Let us take in feet $KB = 1,5$; $BC = BF = a$; $BD = b$. By the common theory of falling bodies, the velocity in KL will be $7,76 \sqrt{(a + b - 1,4)}$; the circular ſection $KL = 0,785\, a^2$. Admitting the air in KL to have acquired the ſame velocity as the water, the quantity of the mixture of the water and air which paſſes in a ſecond through KL is $= 6,1\, a^2 \sqrt{(a + b - 1.4)}$. We muſt deduct from the quantity $(a + b - 1,4)$ that height which anſwers to the velocity the water muſt loſe by that portion of velocity which it communicates to the air laterally introduced; but this quantity is ſo ſmall that it may be neglected in the calculation. The water which paſſes in the ſame time of one ſecond through BC is $= 0,4\, a^2 \sqrt{(a + 0,1)}$. Conſequently, the quantity of air which paſſes in one ſecond through KL, will be $= 6,1\, a^2 \sqrt{(a + b - 1,4)} - 0,4\, a^2 \sqrt{(a + 0,1)}$, taking the air itſelf, even in its ordinary ſtate of compreſſion, under the weight of the atmoſphere. It will be proper, in practical applications, to deduct one-fourth from this quantity; 1. On account of the ſhocks which the ſcattered water ſuſtains againſt the inferior part of the tube, which deprive it of part of its motion; and, 2. Becauſe it muſt happen that the air in LK will not, in all its parts, have acquired the ſame velocity as the water.

If the pipe O do not diſcharge the whole quantity of air afforded by the fall, the water will deſcend at XZ; the point K will riſe in the pipe, the afflux of air will diminiſh, and part of the wind will iſſue out of the lower lateral apertures of the pipe BK.

We ſhall not here examine the greater or leſs degree of perfection of the different forms of water-blowing machines which are uſed at various iron forges; ſuch as thoſe of the Catalans, and elſewhere. Theſe points may be eaſily determined from the principles here laid down, compared with thoſe eſtabliſhed in the articles *Resistance of Fluids (Encycl.)*, and Dynamics (*Supplement*).

WATERBOROUGH, a townſhip of the Diſtrict of Maine, York county, on Mouſam river, 15 miles N. W. of Wells, and 110 from Boſton. It was incorporated in 1787, and contains 905 inhabitants.—*Morse.*

WATERBURY, a townſhip of Vermont, in Chittenden county, ſeparated from Duxbury on the ſouthweſt by Onion river. It contains 93 inhabitants.—*ib.*

Waterbury, the north-weſternmoſt townſhip of New-Haven county, Connecticut, called by the Indians *Matteluck*. It was ſettled in 1671, and is divided into the pariſhes of Northbury, Salem, and South-Britain.—*ib.*

WATEREE, a branch of Santee river, South Carolina.—*ib.*

WATERFORD, a plantation in Cumberland county, Diſtrict of Maine, ſouth-eaſt of Orangeton, or Greenland.—*ib.*

Waterford, a new townſhip in York county, Diſtrict of Maine, incorporated February, 1797, formerly a part of Waterborough.—*ib.*

Waterford, a townſhip of New Jerſey, in Glouceſter county.—*ib.*

Waterford, a neat village of New York, in the townſhip of Half Moon.—*ib.*

WATERLAND, an iſland in the South Pacific Ocean, ſo named by Le Maire. S. lat. 14 46, weſt long. 144 10.—*ib.*

WATERQUECHIE, or *Quechy*, a ſmall river of Vermont, which empties into Connecticut river in Hartland.—*ib.*

WATERTOWN, a very pleaſant town in Middleſex county, Maſſachuſetts, 7 miles weſt by north-weſt of Boſton. Charles river is navigable for boats to this town, 7 miles from its mouth in Boſton harbour. The townſhip contains 1091 inhabitants, and was incorporated in 1630. That celebrated apoſtle of the Indians, the Rev. Mr Eliot, relates that in the year 1670, a ſtrange phenomenon appeared in a great pond at Watertown, where the fiſh all died; and as many as could, thruſt themſelves on ſhore, and there died. It was eſtimated that not leſs than 20 cart-loads lay dead at once round the pond. An eel was found alive in the ſandy border of the pond, and upon being caſt again into its natural element, it wriggled out again, as faſt as it could, and died on the ſhore. The cattle, accuſtomed

stomed to the water, refused to drink it for 3 days, after which they drank as usual. When the fish began to come ashore, before they died, many were taken both by English and Indians and eaten without any injury.—*ib.*

WATERTOWN, a township in Litchfield county, Connecticut. It is about 26 miles N. N. W. of New-Haven.—*ib.*

WATER VLIET, an extensive township of New-York, Albany county, on the west side of Hudson's river, and includes the village of Hamilton, and the islands in the river nearest the west side. It is bounded west by the manor of Rensselaerwyck, and contained, in 1790, 7,419 inhabitants, including 707 slaves. In 1796, there were 600 of the inhabitants qualified electors.—*ib.*

WATLAND *Island,* one of the Bahama Islands in the West-Indies. The S. point is in lat. 24 N. and long. 74 west.—*ib.*

WATSON, *Fort,* in S. Carolina, was situated on the N. E. bank of Santee river, about half way between the mouth of the Congaree and Nelson's Fort, on the bend of the river opposite the Eutaw Springs. Its garrison of 114 men being besieged by Gen. Greene, surrendered in April, 1781. He then marched with his main force against Camden higher up the river.—*ib.*

WAUKEAGUE, a village in the township of Sullivan, in the District of Maine, 9 miles from Desert Island.—*ib.*

WAWASINK, a village in New-York, on Rondout Kill, a branch of Wallkill, 7 miles west of New Paltz, and 12 south-west of Esopus.—*ib.*

WAWIACHTANOS, and *Twichtwees,* two Indian tribes, residing chiefly between Sciota and Wabash rivers.—*ib.*

WAYNE, a new county in the N. W. Territory, laid out in the fall of 1796, including the settlements of Detroit and Michillimakkinak.—*ib.*

WAYNE, a county of Newbern district, N. Carolina; bounded N. by Edgcombe, and S. by Glasgow. It contains 6,133 inhabitants, inclusive of 1,537 slaves.—*ib.*

WAYNE, a township of Pennsylvania, situated in Mifflin county.—*ib.*

WAYNE, *Fort,* in the N. W. Territory, is situated at the head of the Miami of the Lake, near the Old Miami Villages, at the confluence of St Joseph's and St Mary's rivers. It is a square fort with bastions at each angle, with a ditch and parapet, and could contain 500 men, but has only 300 with 16 pieces of cannon. It is 150 miles north by west of Cincinnati, and 200 west by south of Fort Defiance. The Indians ceded to the United States a tract of land 6 miles square, where this fort stands, at the late treaty of peace at Greenville.—*ib.*

WAYNESBOROUGH, a post-town of N. Carolina, 24 miles from Kingston, 50 S. E. from Raleigh, and 498 from Philadelphia.—*ib.*

WAYNESBOROUGH, a post-town in Burk county, Georgia, 30 miles south of Augusta, 25 north-east of Louisville. No river of consequence passes near this town; yet being the place where both the superior and inferior courts are held, it is in a prosperous condition.—*ib.*

WEARE, a township of New-Hampshire, situated in Hillsborough county, 18 miles south-westerly of Concord, 60 west of Portsmouth, and 70 north-west of Boston. It was incorporated in 1764, and contains 1924 inhabitants.—*ib.*

WEATHERSFIELD, a township of Vermont, Windsor county, on the west side of Connecticut river, between Windsor on the north, and Springfield on the south. Ascutney Mountain lies partly in this township, and in that of Windsor. It is a flourishing town, and contains 1097 inhabitants.—*ib.*

WEATHERSFIELD, a post-town of Connecticut, pleasantly situated in Hartford county, on the west side of Connecticut river, 4 miles S. of Hartford, 11 N. of Middleton, 36 N. by E. of New-Haven, and 218 N. E. of Philadelphia. This town was settled in 1635 or 1636, by emigrants from Dorchester in Massachusetts, and has a fertile and luxuriant soil. It consists of between 200 and 300 houses, and has a very elegant brick meeting-house for Congregationalists. The inhabitants are generally wealthy farmers; and besides the common productions of the country, raise great quantities of onions, which are exported to different parts of the United States, and to the West-Indies.—*ib.*

WEATHERFORD's *Place, Charles,* an Indian house and plantation of that name, on the eastern side of Alabama river, above M'Gillivray's sister's place, and a good way below the junction of Tallapoosee and Coosa rivers.—*ib.*

WEAUCTENEAU *Towns,* Indian villages on Wabash river, destroyed by Generals Scott and Wilkinson in 1791.—*ib.*

WEAUS, or *Weeas,* an Indian tribe whose towns lie on the head waters of Wabash river. At the treaty of Greenville they ceded a tract of land, 6 miles square, to the United States.—*ib.*

WEAVER's *Lake,* in the State of New-York, is 3 miles north-west of Lake Otsego. It is 2 miles long and 1½ broad.—*ib.*

WEAVING (see *Encycl.*) is an operation, which, by means of a well-known instrument called the *weaving-loom,* has hitherto been performed by bodily labour. That labour is pretty severe; and Mr Robert Millar, an ingenious calico-printer in the county of Dumbarton, Scotland, wishing to lessen it, invented, some years ago, a weaving-loom, which may be wrought by water, steam, horses, or any other power. For his invention he received a patent, dated June 26th 1796; and though truth compels us to say, that we do not think it likely to emulate the spinning machine of Arkwright, it is sufficiently ingenious to deserve notice in a Work of this kind. The following is his own description of his patent weaving-loom:

Fig. 1. (Plate L.) represents a side view of the loom, AA, BB, CC, DD, being the frame. *a* is an axis (which we shall call the spindle) across the frame. On this axis is a sheeve *b*, two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part *c*, where it is filled up to the top; a lever *d* rests on the bottom of this groove, and is lifted up by it when the elevation *c* comes round to the situation represented in the figure. By this motion, the lever *d* acts on the ratchet-wheel *e* by the catch *t*, and draws it forward one tooth, each revolution of the sheeve. This ratchet wheel is in an iron frame *g g*, which also properly

perly carries the two catches *t* and *u*, which are connected with it at *v*. The catch *u* holds the ratchet-wheel in its position, while the lever *d* and the catch *t*, are moved by the groove *c* in the sheeve. On the arbor of the ratchet is a small pinion *h*, working in the wheel *f*; this wheel is fixed on the end of the roller *e* of fig. 3. On the side of the sheeve *b* is fixed a wiper *k*, which lifts the treadle *l*. This treadle turns on its joints in the sheeve E, which is fixed to the side of the frame A and D; it is kept pressing on the bottom of the groove in the sheeve by a spring *m*, fixed to the frame side A, and having a slender rod *n* from its extremity, joining it with the treadle at *l*. From the point of the treadle there goes a belt *o*, which passes over the pulley *p*, which is seen edgewise in this figure, and is joined to the top of the fly pin *q*, of fig. 2. At the end of the frame A is the short post F; on this rests the yarn beam *j*, having a sheeve *r*, over which passes a cord, having a weight *s* suspended to it. The other end of this cord is fastened to the spring *v*; the weight causes the yarn-beam to stretch the web from the ratchet wheel *e*, with its catch *u*; and the spring *v* allows the rope to slide on the sheeve as the ratchet is drawn round during the working.

Fig. 2. is a front view of the loom. *a a* is the spindle which carries the sheeve *b*, and the wipers *d* and *d*, which move the treadles *w*, *w*, of fig. 1. These use the treadles of the headles, with which they are connected by cords from the shafts of the headles *s*, *s*. From the upper shaft there go two leathern belts *f*, *f*, to the roller *y*, furnished each with a buckle, for tightening them at pleasure. The two wipers *c*, *c*, on the shaft *a*, which serve for taking back the lay, have the two treadles *x*, *x*, in fig. 3. with a belt from each passing over the roller *h 2* of fig. 1. and fixed to the sword of the lay. From the swords of the lay forward is fixed a belt to each end of the roller *i*; from this roller there goes a cord to the spring *j*, which serves for taking forward the lay which is hinged on the rocking tree *t*. The star-wheel *b* of fig. 3. and the sheeve *b* of fig. 1. are fixed to the opposite ends of the spindle *a* without the frame; and both the wheel and sheeve have a wiper *k* fixed to them for moving the treadles. In order to drive the shuttle, the belts *o*, *o*, go from the points of the treadles, over the pulleys *p*, *p*, to the top of the fly-pin *q*: This turns on a pin joint in a rail *r*, which goes across the loom. From its lower end there go two small cords to the shuttle drivers *g*, *g*, which slide on the iron rods *n*, *n*. A long iron rod *v* goes across the lay, and is hung on two centres at the ends. In this rod *v* are fixed two small crooked wires *w*, *w*, which are more distinctly marked in the little figure *w* above, which represents a section of the lay. The dot at the lower end of the wire *w*, in this figure, is the section of the rod *v*. The shuttle passes between these wires and the lay every shot, and lifts them up, causing the rod *v* to turn round a little. But if the shuttle should not pass these wires, nor lift them, it would be drawn home by the lay, and destroy the web. To prevent this, there is fixed on one end of the rod *v* a stout crooked wire *z*, having a broad or flat head, which naturally rests on a plate of iron, marked and fixed to the back of the lay. This plate has a slit in its middle about an inch deep. In this slit rests the rod *a 2* of fig. 3. on which is a short stud, which is caught by the wire *z* when the wire *w* is not lifted back by the passing shuttle. This will stop the lay from coming home, and will set off the loom.

Fig. 3. is another side-view of the loom opposite to fig. 1. On the spindle *a* is the star-wheel *b*, on the outside of the loom-frame, on the arms of which wheel is fixed the wiper *k*, as the similar wiper is fixed to the sheeves on the other end of the spindle. The wipers which drive the shuttles are fixed on opposite squares of the spindle, and work alternately. Below the star-wheel is a pinion *c*, which is on a round spindle, turned by the water-wheel, by means of a wheel on this spindle. In a wheel on this spindle are two studs, on which the pinion *c* slides off and on as the loom is set off and on by the lever *d*. At the farther end of this lever is the weight *s*, hanging by a cord which passes over a pulley *t*, fixed at the outer end of the spring-catch on which the lever *d* rests; and thus the loom is drawn in at the upper end of the lever *d*. But when the shuttle does not lift the wire *z*, it catches on the stud on the rod *a 2*, which is connected with the spring-catch, and the lever *d* flies off with the weight *s*, and the loom stops working. On the head of the post F is the yarn-beam. The rollers *e* and *f* are cylinders, pressed together by a screw-lever, and take away the cloth between them at a proper rate. In the roller *f* is a groove for a band for driving the roller *g*, on which the cloth winds itself as it is wrought. Wherever springs are mentioned to be used in the above description, weights may be used in their stead, and to the same effect, and more especially upon the treadle of fig. 1. for driving the shuttle.

WEBHAMET *River*, in the District of Maine, is the principal entrance by water to the town of Wells, in York county. It has a barred harbour.—*Morse.*

WECHQUETANK, a Moravian settlement made by the United Brethren, in Pennsylvania, behind the Blue Mountains. In 1760, the Bethlehem congregation purchased 1400 acres of land for the Christian Indians. In 1763, it was destroyed by white savages, who inhabited near Lancaster; they likewise murdered many of the peaceable Indians settled here. It was finally destroyed by the Americans during the late war. It lies about 30 miles north-west by west of Bethlehem. —*ib.*

WEIGHTS AND MEASURES, in commerce, are so various, not only in different countries, but even in different provinces of the same country, and this variation is the source of so much inconveniency in trade, that writers on political and commercial economy have proposed various methods for fixing an universal and immoveable standard of weights and measures for all ages and nations. Sir James Stewart Denham's speculations on this subject have been noticed in his life published in this *Supplement*; Mr Whitehurst's ingenious contrivance for establishing a standard of weights and measures has been mentioned under the title MEASURE (*Encycl.*); and the new table of weights and measures, which the French republicans wish to impose upon all Europe, is given (*Encycl.*) under the title REVOLUTION, n° 183.

As these measures occur frequently, even in English translations of French books of value, we shall here give such an account of them as may enable the reader to reduce them with ease to the English standards.

They

They are of five kinds; *measures of length, of capacity, of weight, of superficies for land, and of wood for fuel.* For every kind, there are many measures of different sizes, one of which has been taken as the basis of all the rest, and its name assumed as the root of their names. Thus METRE is called the principal measure of length; LITRE, of capacity; GRAMME, of weight; ARE, of superficies of land; and STERE, of wood for fuel. These words being the radical terms of the names of other measures of length, capacity, &c. a relation is hereby preserved between the names.

The measures of length above the *metre*, are ten times, a hundred times, a thousand times, ten thousand times, greater than the metre. The measures of length below the metre, are ten times, a hundred times, a thousand times, less. To form the names of these measures, other words which indicate the relations of *ten times*, a *hundred times*, greater; and of *ten times*, a *hundred times*, less, &c. are placed before the word *metre*. The same annexes have been used to form the names of measures, greater or less, than the *litre*, the *gramme*, &c. It is necessary, therefore, to state in this place the English equivalents of only the *metre*, the *litre*, the *gramme*, the *are*, and the *stere*.

The METRE = 3.28084 feet English.

The LITRE = 61.0243 cubic inches, or $1\frac{103}{141}$ pint ale measure.

The GRAMME, or cubic *centi-metre* of water, at the freezing point, = $\frac{1}{453}$ lb. averd. or $\frac{1}{28}$ of an ounce, or $\frac{16}{25}$ of a dram nearly.

The ARE = $1076\frac{2}{5}$ square feet, or $119\frac{3}{5}$ square yards, or $\frac{1}{40}$ of an acre nearly.

The STERE, or cubic metre = 35.31467 cubic feet.

The most part of the English, not choosing to adopt the weights and measures prescribed to them by the French Convention and the National Institute, Sir George Shuckburgh Evelyn, Bart. turned his attention to this subject, and published, in the Philosophical Transactions for 1798, an account of some endeavours to ascertain a standard of weights and measures. The principles upon which he proceeded are the same with Mr Whitehurst's; but he has carried his experiments much farther than his predecessor, and seems to have conducted them with greater accuracy. His memoir is hardly susceptible of abridgment; and our limits do not permit us to insert it entire. This is indeed unnecessary, if it be true, as another ingenious gentleman alleges*, that we are in the actual possession, and the constant use, of a standard both for weight and measure, as invariable as that now used in France. This standard he finds in the foot measure, and in the avoirdupose, or, as he thinks it ought to be called, the *decade* ounce weight.

* H. Goodwin Esq; in *Nicholson's Journal*, vol. iv. p. 103, &c.

The decade ounce weight of pure rain, or distilled water, at 60° of heat, is generally allowed to be equal in bulk to the one thousandth part of the cubic foot. Were 44.3511 parts out of 10000, or about $\frac{1}{225}$th part added to the present Winchester bushel, that bushel would then contain exactly 10 cubic feet or 10000 oz. of distilled water, at 60° of heat.

Our author then gives comparative tables between this system and that which is now established in France. Taking the metre at 3 French feet, and 11.296 lines †, and the French foot to be to the English as 1 : 1.065752004 ‡, one French foot will be equal to 10 65752004 English decades, or tenths of an English foot: hence he calculates the following

† *Journal de Phys.* vol. v. p. 460.

‡ *Phil. Transf.* 1768, p. 326. and *Connoissance des Temps*, 1795.

COMPARATIVE TABLES, English with French.

LONG MEASURE.

Long decade. Metre. Metre. Long decades.

1 = 0.03047983 ferè 1 = { 32 808583358, &c. or inches 39 3703.

SQUARE MEASURE.

Square decades. Ares, Ares. Square decades.

1 = 0 0000092902 ferè 1 = { 107640.3142, or sqr. inch. 155002.052448

CUBE MEASURE.

Cube decades. Litres. Litre. Cube decades.

1 = 0 02831637 ferè 1 = { 35.3152622, &c. or cub. inch. 61.0247727

WEIGHTS.

Avoird. or decade oz. Grammes. Gramme. Decade oz.

1 = 28.31637 ferè 1 = { 0.03531526, &c. or grains, 15.45042625

{ Long, Square, or Cube, } decades are reduced to { Long Square, or Cube, } English inches by multiplying by { 1.2, 1.44, 1.728 }

and decade ounces are reduced to grains.

containing { 7000, or 5760, } to the lb. { Avoird. Troy, } by multiplying the ounce by 437.5 = the number of grains in an avoirdupoise ounce.

Our author, who seems to have paid much attention to weights and measures, observes, that a standard measure for the purposes of trade, in particular, as well as for others, that would uniformly give an accurate result, and could be easily made, examined, and ascertained, by common mechanics, which neither our present liquid nor dry measures evidently can, would surely be an acquisition of great value. Such an one, he presumes, would be the following: A square pyramid, whose perpendicular height is exactly thrice the length of the side of the base: for such an one, and every section of it, made by a plane parallel to its base, would, in the first instance, possess, and, in every subdivision, retain these remarkable properties.

1st, Similar comparative dimensions to those above given, for the original pyramid, *i. e.* every smaller pyramid, formed by the above-mentioned parallel section, would have its perpendicular height thrice the length of the side of its base; and,

2dly, The length of the side of each base will always indicate, or equal the cube root of the solid content of the pyramid; *e. g.* If the length of the side of the base be 3, the solid content will be the cube of 3, *viz.* $3 \times 3 \times 3 = 27$.

We do not perceive very clearly the great value of this standard; but Mr Goodwyn says, that he has been many years in the habit of using a pyramid measure to examine corn; and is perfectly convinced that such a one will indicate a far more accurate result than can arise

Fig.1.

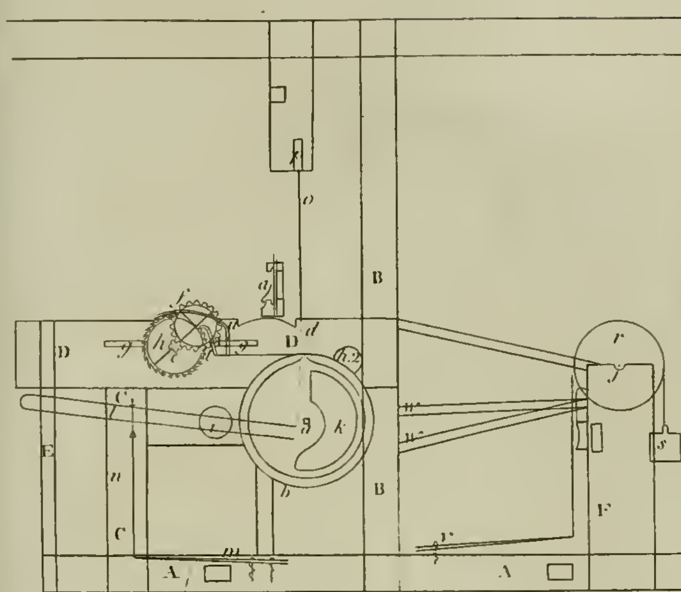

Fig.2.

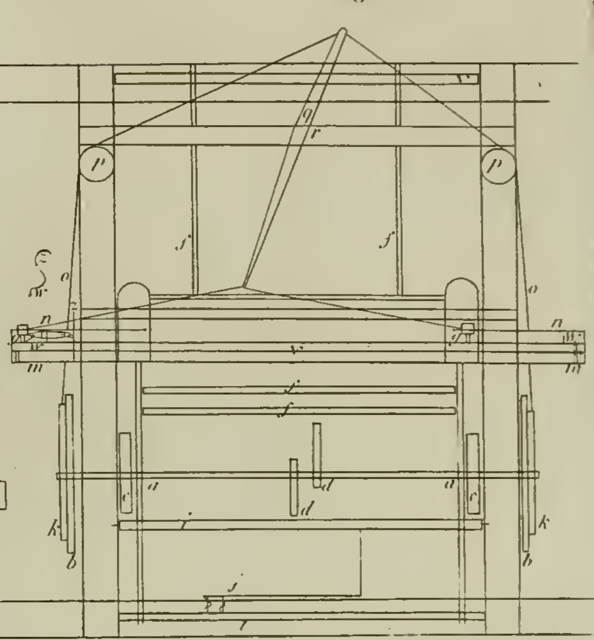

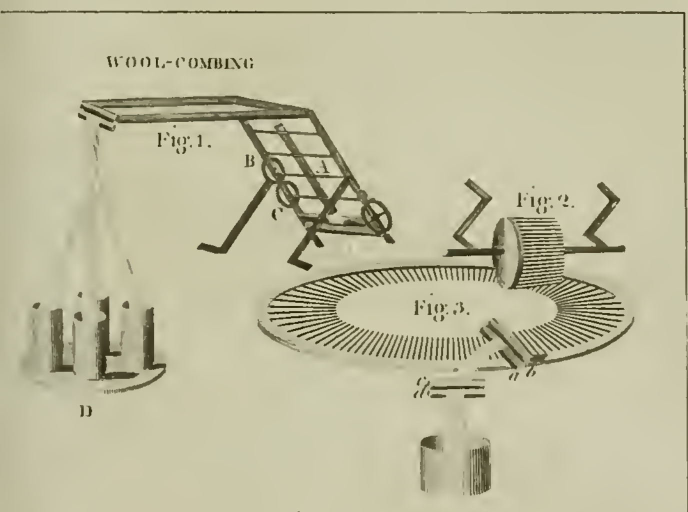

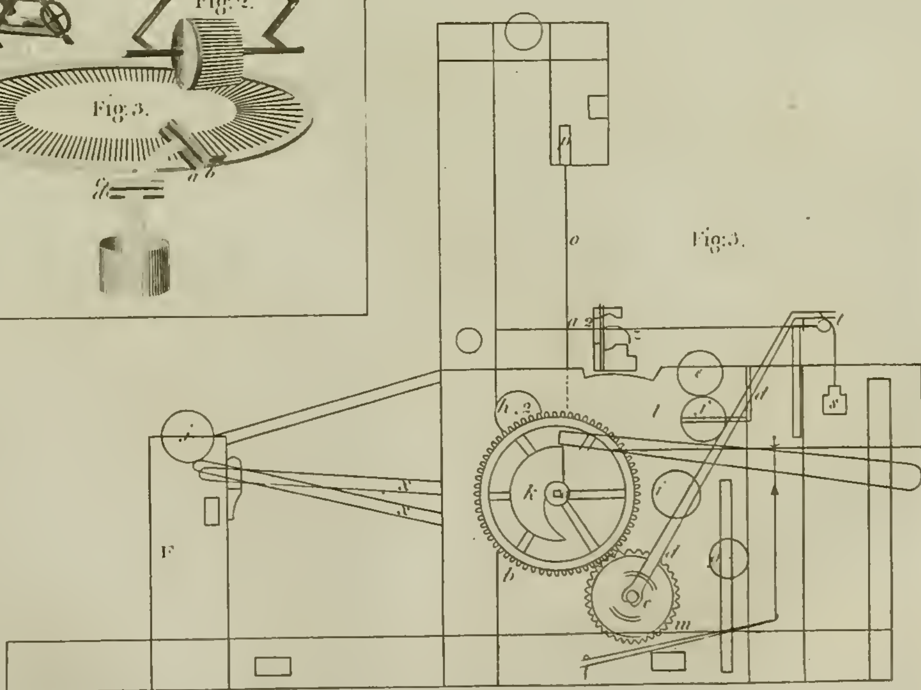

arise from the manner in which corn is measured by the bushel. This we are bound to believe; for it is absurd to oppose theories to a fact ascertained by experience.

WEISENBERG, a township of Pennsylvania, in Northampton county.—*Morse*.

WELCH *Mountains*, are situated in Chester county, Pennsylvania. Besides other streams, Brandywine Creek rises here.—*ib*.

Welch *Tract*, a small territory of Pennsylvania, so named because first settled by Welchmen. There are a number of small towns in it, as Haverford-West, Merioneth, &c. It is pretty thickly inhabited by an industrious, hardy and thriving people.—*ib*.

WELCOME, *Sir Thomas Roes*, or *Ne Ultra*, a bay or strait in that part of Hudson's Bay which runs up to the N. round from Cape Southampton, opening between lat. 62 and 63 N. On the west or north shore is a fair head land called the Hope by Captain Middleton, in lat. 66 30 N.—*ib*.

WELLFLEET, a township of Massachusetts, in Barnstable county, situated on the peninsula called Cape Cod; S. E. from Boston, distant by land 105 miles, by water 60, and from Plymouth light-house 8 leagues. The harbour is large, indented within with creeks, where vessels of 70 or 80 tons may lie safe in what is called the Deep Hole. The land is barren, and its timber is small pitch-pine and oak. Before it was incorporated in 1763, it was called the *North Precinct of Eastham*, and was originally included in the Indian *Skeekeet* and *Pamet*. In 1790, it contained 1117 inhabitants. Since the memory of people now living, there have been in this small town 30 pair of twins, besides two births that produced three each. The method of killing gulls in the gull-house, is no doubt an Indian invention, and also that of killing birds and fowl upon the beach in dark nights. The gull-house is built with crotches fixed in the ground on the beach, and covered with poles, the sides being covered with stakes and sea weed, and the poles on the top covered with lean whale. The man being placed within, is not discovered by the fowls, and while they are contending for and eating the fish, he draws them in one by one between the poles, until he has collected 40 or 50. This number has often been taken in a morning. The method of killing small birds and fowl that perch on the beach, is by making a light; the present mode is with hogs lard in a frying-pan; but the Indians are supposed to have used a pine torch. Birds, in a dark night, will flock to the light, and may be killed with a walking-cane. It must be curious to a countryman who lives at a distance from the sea, to be acquainted with the method of killing black-fish. Their size is from 4 to 5 tons weight, when full grown. When they come within the harbours, boats surround them, and they are as easily driven on shore, as cattle or sheep are driven on the land. The tide leaves them, and they are easily killed. They are a fish of the whale kind, and will average a barrel of oil each: 400 have been seen at one time on the shore. Of late years these fish rarely come into the harbours.—*ib*.

WELLS, a small, but rapid river of Vermont, which, after a short S. E. course, empties into Connecticut river, below the Narrows, and in the N. E. corner of Newbury. Its mouth is 40 yards wide.—*ib*.

Wells, a township of Vermont, Rutland county, between Pawlet and Poultney, and contains 622 inhabitants. Lake St Austin lies in this township, and is 3 miles long, and 1 broad.—*ib*.

Wells, a post-town of the District of Maine, in York county, situated on the bay of its name, about half way between Biddeford and York, and 88 miles N. by E. of Boston, and 441 from Philadelphia. This township is about 10 miles long, and 7 broad; was incorporated in 1653, and contains 3,070 inhabitants. It is bounded S. E. by that part of the sea called Wells Bay, and N. E. by Kennebunk river, which separates it from Arundel. The small river Negunket, perhaps formerly Oguntiquit, has no navigation, nor mills of any value, but noticed, about 150 years ago, as the boundary between York and Wells. The tide through Piscataqua bay urges itself into the marshes at Wells, a few miles E. of Negunket, and forms a harbour for small vessels. Further E. in this township the small river Mousom is found coming from ponds of that name about 20 miles from the sea. Several mills are upon the river, and the inhabitants are opening a harbour by means of a canal. Webhamet river is the principal entrance to this town by water.—*ib*.

Wells *Bay*, in the township above mentioned, lies between Capes Porpoise and Neddock. The course from the latter to Wells Bar, is N. by E. 4 leagues. —*ib*.

Well's *Falls*, in Delaware river, lie 13 miles N. W. of Trenton, in New-Jersey.—*ib*.

WENDELL, a township of Massachusetts, in Hampshire county, 80 miles N. W. of Boston. It was incorporated in 1781, and contains 519 inhabitants.—*ib*.

Wendell, a township of New Hampshire, Cheshire county, about 15 miles N. E. of Charlestown, containing 267 inhabitants. It was called Saville, before its incorporation in 1781.—*ib*.

WENHAM, a township of Massachusetts, Essex county, between Ipswich and Beverly; 26 miles N. E. by N. of Boston. It was incorporated in 1643, and contains 502 inhabitants. Here is a large pond, well stored with fish, from which, and its vicinity to Salem, it was, with whimsical piety, called *Enon*, by the first settlers.—*ib*.

WENMAN, one of the Gallipago Islands, on the coast of Peru, situated W. of Cape Francisco.—*ib*.

WENTWORTH, a township of New Hampshire, Grafton county, containing 241 inhabitants. It was incorporated in 1766, and is S. E. of Oxford, adjoining. —*ib*.

WESEL, a village of New-Jersey, Essex county, on Pasaic river, 2 miles north-westward of Acquakenunk, and 5 westward of Hakkensack.—*ib*.

WEST, or *Wantastiquek*, a river of Vermont, has its main source in Bromley, about 3 miles S. E. from the head of Otter Creek. After receiving 7 or 8 smaller streams, and running about 37 miles, it falls into Connecticut river at Brattleborough. It is the largest of the streams on the east side of the Green Mountains; and at its mouth is about 15 rods wide, and 10 or 12 feet deep. A number of figures, or inscriptions, are yet to be seen upon the rocks at the mouth of this river, seeming to allude to the affairs of war among the Indians; but their rudeness and awkwardness denote that the formers of them were at a great remove from the knowledge of any alphabet.—*ib*.

WEST RIVER *Mountain*, in New Hampshire, in the

the township of Chesterfield, lies opposite to the mouth of West river; and from this part of Connecticut river to Piscataqua Harbour on the east is 90 miles, the broadest part of the State. Here are visible appearances of volcanic eruptions. About the year 1730, the garrison of Fort Dummer, 4 miles distant, was alarmed with frequent explosions of fire and smoke, emitted by the mountain. Similar appearances have been observed since.—*ib.*

WEST *Bay*, a large bay of Lake Superior, at its westernmost extremity, having the 12 isles at its mouth. It receives St Louis river from the west.—*ib.*

WEST BETHLEHEM, a township of Washington county, Pennsylvania.—*ib.*

WESTBOROUGH, a township of Massachusetts, Worcester county, 34 miles west-south-west of Boston, and 13 east of Worcester, was incorporated in 1717. Among other singular occurrences in the Indian wars, the strange fortune of Silas and Timothy Rice is worthy of notice. They were sons of Mr Edmond Rice, one of the first settlers in this town, and carried off by the Indians on August 8, 1704, the one 9 the other 7 years of age. They lost their mother tongue, had Indian wives, and children by them, and lived at *Cagnawaga*. Silas was named *Tookanowras*, and Timothy, *Oughtsorongoughton*. Timothy recommended himself so much to the Indians by his penetration, courage, strength, and warlike spirit, that he arrived to be the third of the six chiefs of the *Cagnawagas*. In 1740 he came down to see his friends. He viewed the house where Mr Rice dwelt, and the place from whence he with the other children were captivated, of both which he retained a clear remembrance; as he did likewise of several elderly persons who were then living, though he had forgot the English language. He returned to Canada, and, it is said, he was the chief who made the speech to Gen. Gage, in behalf of the Cagnawagas, after the reduction of Montreal. These men were alive in 1790.—*ib.*

WEST *Camp*, a thriving village of New York, containing about 60 houses, in Columbia county, on the east side of Hudson's river, 7 miles above Red Hook, and 13 north of New York city.—*ib.*

WEST-CHESTER, a county of New York; bounded north by Dutchess county, south by Long-Island Sound, west by Hudson's river, and east by the State of Connecticut. It includes Captain's Islands and all the islands in the sound, to the east of Frogs Neck, and to the northward of the main channel. In 1790, it contained 24,003 inhabitants, including 1419 slaves. In 1796, there were, in its 21 townships, 3,243 of the inhabitants qualified electors.—*ib.*

West-Chester, the chief township of the above county; lying partly on the Sound, about 15 miles easterly of New York city. It was much impoverished in the late war, and contains 1203 inhabitants; of whom 164 are electors, and 242 slaves.—*ib.*

West-Chester, the chief town of Chester county, Pennsylvania, containing about 50 houses, a court-house, stone gaol, and a Roman Catholic church. It is about 25 miles west of Philadelphia.—*ib.*

WESTERLY, a post-town on the sea coast of Washington county, Rhode-Island, and separated from Stonington in Connecticut by Paucatuck river, 36 miles west by south of Newport, and 256 from Philadelphia. The inhabitants carry on a brisk coasting trade, and are extensively engaged in the fisheries. The township contains 2,298 inhabitants, of whom 10 are slaves.—*ib.*

WESTERN, a township of Massachusetts, situated in the south-west corner of Worcester county, 18 miles east by north of Springfield, 29 in the same direction from Worcester, and 73 south-west by south of Boston.—*ib.*

Western, *Fort*, in the District of Maine, was erected in 1752, on the east bank of the small fall which terminates the navigation of Kennebeck river. It is 18 miles from Taconnet Fall. It is in the township of Harwington, Lincoln county. A company was incorporated in February 1796, to build a bridge over the river at this place.—*ib.*

Western *Precinct*, in Somerset county, New-Jersey, contains 1,875 inhabitants, including 317 slaves.—*ib.*

WESTFIELD, a township of Vermont, Orleans county, south of Jay.—*ib.*

Westfield, a pleasant post-town of Massachusetts, Hampshire county, on the river of this name, in a curious vale, 10 miles west of Springfield, 34 east of Stockbridge, 52 south-west of Worcester, 105 west-south-west of Boston, and 260 from Philadelphia. It contains a Congregational church, an academy, and about 50 or 60 compact houses. The township was incorporated in 1669, and contains 2,204 inhabitants.—*ib.*

Westfield, a small river of Massachusetts, which rises in Berkshire county, and runs nearly a south-east course through Middlefield, Westfield, and West-Springfield, where it empties into the Connecticut, by a mouth about 30 yards wide.—*ib.*

Westfield, a township of New York, Washington county, bounded southerly by Kingsbury, and northerly by Whitehall. It contains 2,103 inhabitants, of whom 186 are electors, and 9 slaves. It lies near Lake George.—*ib.*

Westfield, in Richmond county, New York, is bounded northerly by the Fresh Kill, easterly by Southfield, and westerly by the Sound. It contains 1151 inhabitants, of whom 131 are electors, and 276 slaves.—*ib.*

Westfield, a small town in Essex county, New Jersey, containing a Presbyterian church, and about 40 compact houses. It is about 7 or 8 miles W. of Elizabeth-Town.—*ib.*

WESTFORD, a township of Vermont, in Chittenden county, N. E. of Colchester, adjoining, and contains 63 inhabitants.—*ib.*

Westford, a township of Massachusetts, situated in Middlesex county, 28 miles N. W. of Boston, and contains 1229 inhabitants. In the year 1792, an academy was established here.—*ib.*

WEST-GREENWICH, a township in Kent county, Rhode-Island, containing 2,054 inhabitants, including 10 slaves.—*ib.*

WESTHAM, a small town of Virginia, Henrico county, on the N. bank of James's river, 6 miles N. W. by W. of Richmond. Here Benedict Arnold destroyed one of the finest founderies for cannon in America, and a large quantity of stores and cannon, in January, 1781.—*ib.*

WESTHAMPTON, a township of Massachusetts, Hampshire county, 7 miles westerly of Northampton, and 109 S. W. by W. of Boston. It contains 683 inhabitants,

bitants, and lies on the W. fide of Connecticut river.—*ib.*

WEST *Harbour*, on the S. coaft of the ifland of Jamaica, is to the N. of Portland Point. There is good anchorage, but expofed to S. and S. E. winds.—*ib.*

WEST-HAVEN, a parifh of the townfhip of New-Haven, in Connecticut, pleafantly fituated on the Harbour and Sound, 3 miles W. S. W. of the city.—*ib.*

WESTMINSTER, a townfhip of Maffachufetts, fituated in Worcefter county, was granted to thofe who did fervice in the Narraganfet war, or their heirs, in 1728, and was then ftyled *Narraganfet, No.* 2. It was incorporated by its prefent name in 1759; and contains 20,000 acres of land, well watered. It is fituated on the height of land between the rivers Merrimack and Connecticut, having ftreams arifing in the town, and running into both. It is about 55 miles from Bofton to the north of weft, and about 22 miles north from Worcefter, and contains 177 dwelling-houfes, and 1176 inhabitants.—*ib.*

Westminster, a confiderable townfhip of Vermont, in Windham county, on Connecticut river, oppofite Walpole in New Hampfhire. It contains 1601 inhabitants. Sexton's river enters the Connecticut in the S. E. corner of the townfhip. Here is a poft-office 18 miles north of Brattleborough, 18 north-weft of Keen, in New Hampfhire, 59 north of Northampton in Maffachufetts, and 329 north-eaft of Philadelphia.—*ib.*

Westminster, the eafternmoft town of Frederick county, Maryland, about 18 miles E. N. E. of Woodfborough, 26 north-weft of Baltimore, and 47 N. by E. of the city of Wafhington.—*ib.*

WESTMORE, the wefternmoft townfhip of Effex county, Vermont. Willoughby Lake lies in this townfhip.—*ib.*

WESTMORELAND, a county of Virginia, bounded north and eaft by Patowmack river, which divides it from Maryland, fouth-eaft by Northumberland, fouth-weft by Richmond, and weft by King George. It contains 7722 inhabitants, of whom 4425 are flaves. This county has the honour of having given birth to George Wafhington, firft Prefident of the United States. The court-houfe in this county is on the fouth bank of Patowmack river, 10 miles N. by E. of Richmond, 16 north-weft of Kinfale, and 289 fouth-weft by fouth of Philadelphia. Here is a poft-office.—*ib.*

Westmoreland, a county of Pennfylvania, bounded north by Lycoming, and fouth by Fayette county, and abounds with iron ore and coal. It contains 11 townfhips and 16,018 inhabitants, including 128 flaves. Chief town, Greenfburg.—*ib.*

Westmoreland, a confiderable townfhip of New Hampfhire, Chefhire county, on the eaftern bank of Connecticut river, between Chefterfield and Walpole, 110 miles from Portfmouth. It was incorporated in 1752, and contains 2,018 inhabitants.—*ib.*

Westmoreland, a townfhip of New-York, in Herkemer county, taken from Whiteftown, and incorporated in 1792. In 1796, it contained 840 inhabitants, of whom 137 were electors. The centre of the town is 6 miles fouth of Fort Schuyler, and 36 north weft of Cooperftown.—*ib.*

Westmoreland, a tract of land in Pennfylvania, bounded eaft by Delaware river, weft by a line drawn due north and fouth 15 miles weft of Wyoming on Sufquehannah river, and between the parallels of 41 and 40 degrees of north lat. was claimed by the State of Connecticut, as within the limits of their original charter, and in 1754 was purchafed of the Six Nations of Indians by the Sufquehannah and Delaware companies, and afterwards fettled by a confiderable colony, under the jurifdiction of Connecticut. This tract was called *Weftmoreland*, and annexed to the county of Litchfield in Connecticut. The Pennfylvanians difputed the claim of Connecticut to thefe lands, and in the progrefs of this bufinefs there was much warm contention and fome bloodfhed. This unhappy difpute has fince been adjufted.—*ib.*

WESTON, a townfhip of Maffachufetts, in Middlefex county, 15 miles weft of Bofton. It was incorporated in 1712, and contains 1,010 inhabitants.—*ib.*

Weston, a townfhip of Connecticut, Fairfield county, north of Fairfield, adjoining.—*ib.*

WEST-POINT, a ftrong fortrefs erected during the revolution, on the W. bank of Hudfon's river, in the ftate of New York, 6 miles above Anthony's Nofe, 7 below Fifh Kill, 22 S. of Poughkeepfie, and about 60 N. of New York city. It is fituated in the midft of the high lands, and is ftrongly fortified by nature as well as art. The principal fort is fituated on a point of land, formed by a fudden bend in the river, and commands it, for a confiderable diftance, above and below. Fort Putnam is fituated a little further back, on an eminence which overlooks the other fort, and commands a greater extent of the river. There are a number of houfes and barracks on the point near the forts. On the oppofite fide of the river, are the ruins of Old Fort Conftitution, with fome barracks going to decay. A number of continental troops are ftationed here to guard the arfenal and ftores of the United States, which are kept at this place. This fortrefs is called the Gibraltar of America, as by reafon of the rocky ridges, rifing one behind another, it is incapable of being invefted by lefs than 20,000 men. The fate of America feemed to hover over this place. It was taken by the Britifh, and afterwards retaken by ftorm, in a very gallant manner, by Gen. Wayne. Benedict Arnold, to whom the important charge of this fort was committed, defigned to have furrendered it up to the Britifh; but Providenee difappointed the treafonable defign, by the moft fimple means. Major Andre, a moft accomplifhed and gallant officer, was taken, tried, and executed as a fpy, and Arnold efcaped. Thus the Britifh exchanged one of their beft officers, for one of the worft men in the American army.—*ib.*

WESTPORT, a flourifhing townfhip of Maffachufetts, Briftol county, 70 miles foutherly of Bofton. It was incorporated in 1787, and contains 2,466 inhabitants.—*ib.*

WESTRINGIA, a new genus of plants defcribed by J. E. Smith, M. D. prefident of the Linnæan Society of London. It was firft difcovered in New Holland by Dr Solander, who called it *Cunila Fruticofa*, though it is totally different from the Cunila (fee that article, *Encycl.*), and more refembles rofemary, from which, however, it is likewife different. Its peculiar character is: *Calyx femiquinquefidus, pentagonus; corolla refupinata, limbo quadrifido, lobo longiore erecto, bipartito: Stamina diftantia, duo breviora (inferiora) abortiva.* Dr

Smith affigns it rather to the *didynamia-angiofpermia*, placing it immediately after the *Teucrium*, than to the *diandria* clafs of plants.

WEST-SPRINGFIELD, a townfhip of Maffachufetts, Hampfhire county, on the W. fide of Connecticut river, oppofite Springfield, about 28 miles N. of Hartford, and 100 W. S. W. of Bofton. In the compact part are about 40 dwelling-houfes, and a Congregational church. The townfhip contains 3 parifhes, and 2,367 inhabitants.—*Morse.*

WEST-STOCKBRIDGE, a townfhip of Maffachufetts, in Berkfhire county, adjoining Stockbridge on the weft, and has the New York line on the north-weft, and lies 150 miles from Bofton. William's river, and its ftreams water the townfhip, and accommodate 3 iron-works, a fulling-mill, a grift-mill, and 2 faw-mills.—*ib.*

WEST-TOWN, a townfhip in Chefter county, Pennfylvania.—*ib.*

WEYBRIDGE, a townfhip of Vermont, in Addifon county, feparated from New-Haven on the N. and E. by Otter Creek. It contains 175 inhabitants. Snake Mountain lies nearly on the line between this townfhip and that of Addifon on the weft.—*ib.*

WEYMOUTH, the *Wessagufcus*, or *Waffaguffet*, of the Indians, a townfhip of Maffachufetts, Norfolk county, incorporated in 1635. It lies 14 miles S. E. of Bofton, and employs fome fmall veffels in the mackarel fifhery. Fore river on the N. W. and Back river on the S. E. include near one half of the townfhip. The cheefe made here is reckoned among the beft brought to Bofton market. It is faid to be one of the oldeft towns in the ftate; Mr Wefton, an Englifh merchant, having made a temporary fettlement here in the fummer 1622. It contains 232 houfes, and 1469 inhabitants.—*ib.*

WHALE COVE *Ifland*, in the northern part of N. America, is the moft northerly of two iflands lying to the S. of Brook Cobham, or Marble Ifland, which is in lat. 63 N. Lovegrove, the other ifland, has a fair opening to the weft of it.—*ib.*

WHALE FISH *Ifland*, in the river Effequibo, on the coaft of S. America, is above the Seven Brothers, or Seven Iflands, and below the Three Brothers.—*ib.*

WHALE *Ifland*, at the mouth of M'Kenzie's river, in the North Sea or Frozen Ocean, on the north coaft of the north-weftern part of North America. N. lat. 69 14.—*ib.*

WHAPPING'S *Creek*, a fmall creek which empties through the eaft bank of Hudfon's river, in the townfhip of Fifh Kill, 8 miles fouth of Poughkeepfie, and 72 north of New York city. Here are two mills, at which confiderable bufinefs is performed.—*ib.*

WHARTON, a townfhip of Fayette county, Pennfylvania.—*ib.*

WHATELY, a townfhip of Maffachufetts, in Hampfhire county, 10 miles north of Northampton, and 105 miles from Bofton. It was incorporated in 1771, and contains 736 inhabitants.—*ib.*

WHEAT (fee Triticum, *Encycl.*) has for fome years paft been at fo very high a price, that every hint for increafing its quantity or improving its quality is intitled to notice. In the Leicefter Journal for the 6th of December 1799, there is an ingenious paper on the fubject of tranfplanting wheat, as a means of providing againft the expected fcarcity of that neceffary of life. It is recommended "to fow, in dry land, at the ufual feafon, as much corn as may be deemed neceffary to plant in the fpring any number of acres which may be occupied with that article in the following year. When the foil is prepared, a furrow is to be made with a very fmall plough and one horfe, in the centre of the ridge or land, returning back in the fame track (this time only of every ridge); then turn towards the left hand, and plough another furrow, about eight or nine inches from the firft furrow, turning always to the left hand, till the whole ridge is finifhed; it will then be formed into trenches, in parallel lines of about eight or nine inches afunder, and imitate what gardeners term drawing of drills. In thefe furrows the plants are to be laid." Mr John Ainfworth of Glen, the experienced author of this communication, fays he has practifed this method with the moft complete fuccefs.

It has been likewife practifed, on a fmall fcale, with equal fuccefs, but we know not in what county. About the end of Auguft 1783, that gentleman threw a fmall quantity of wheat, which near two years before had been fteeped and limed (fee Wheat, *Encycl.*) into an unmanured corner of his garden. In the beginning of February following he had a piece of ground (alfo unmanured) dug in an open part of his orchard, and he tranfplanted it on beds of fix rows wide, at nine inches afunder every way. It tillered, and fpread over the ground fo completely, as to prevent even a weed growing among it. It produced admirable corn, and at the rate of near four quarters per acre.

From accurate calculations which he then made, he found that an acre, fuppofing the feed to be very good, and the plants fet at the diftance above menttioned, would require only *half a peck* of feed.

Befides the faving of the feed, there are two other material advantages which attend fuch a method; one is, that fome fuitable crop may be on the ground all the winter for ufe; and the other is, that ploughing the ground fo late as February, will effectually bury and deftroy thofe weeds which were beginning to vegetate; and before others can fpring up, the corn plants have taken to the ground, and fo fpread over it that the weeds cannot rife, by which means there is a very clean crop, and all the cuftomary expenfe for weeding is faved.

This author feems to think that wheat will thrive as well, and produce as full a crop, when fown in the fpring, as if it had been committed to the ground in the preceding autumn. In the fouthern counties of England we doubt not but it may; but the cafe is otherwife in Scotland, where the fpring is not fo early, and where from the narrownefs of the ifland, the froft is feldom fo fevere. We agree, however, with Dr Pike, in thinking it a pity that the way of fetting wheat (as done in Norfolk and Suffolk) is not every where more general. The procefs is indeed tedious and troublefome; and we have often wondered that, among the numberlefs machines lately contrived to leffen manual labour, none has been invented for dibbling wheat expeditioufly and accurately. We are therefore pleafed to learn, that Dr Pike himfelf has turned his attention to the fubject, and hopes in the courfe of this year (1800) to prefent the public with a *method of fetting wheat at* PERFECTLY EXACT *diftances through a whole field, and as* EXPEDITIOUSLY *as the common broadcaft fowing, which can therefore be applied to farms of any magnitude;*

nitude; and when a peck of feed is found to be sufficient for an acre (and in fome land much lefs), the faving on a large farm muft be immenfe. We truft to the liberality of his profeffion, that he will not take out a patent for his invention.

Though we have elfewhere given the ufual recipes for preventing fmut in wheat, it would be improper to conclude this article without mentioning the very fimple one which Mr Wagftaffe of Norwich has uniformly found attended with complete fuccefs. This confifts in nothing more than immerfing the feed in pure water, and repeatedly fcouring it therein, juft before it is fown or dibbled in the foil. Whether well, fpring, or river water be ufed, is indifferent; but repeated ftirring and change of water is effential to remove the particles of infection that may have imperceptibly adhered to the feeds thus purified. The fubfequent crop will be perfect in itfelf, and its feeds, he fays, fucceffively fo likewife, if there are no adjacent fields from whence this contamination may be wafted. He recommends the fame wafhing, and for the fame reafon, of barley and oats before they be fown.

WHEELING, or *Wheelin*, a poft-town of Virginia, fituated at the mouth of a creek on the eaft bank of Ohio river, 10 miles above Grave Creek, 18 fouth-weft of Weft Liberty, and 61 fouth-weft of Pittfburg. Not far from this place, a wall has been difcovered fome feet under the earth, very regularly built, apparently the work of art. It is 363 miles from Philadelphia.—*Morse.*

WHEELOCK, a townfhip of Vermont, in Caledonia county, about 20 miles north-weft of Littleton, and contains 33 inhabitants.—*ib.*

WHETSTONE *Fort* is on the north fide of Patapfco river, and weft fide of the mouth of Baltimore Harbour, in Maryland. It is oppofite Goffuch Point, 2½ miles eafterly from the Baltimore Company's iron-works, at the mouth of Gwinns Falls.—*ib.*

WHIPPANY, a village of New Jerfey, Morris county, on a branch of Paffaick river, nearly 5 miles N. E. of Morriftown.—*ib.*

WHIRL, or *Suck*, in Tenneffee river, lies in about lat. 35 N.—*ib.*

WHITE, a river or torrent iffuing from the mountain of fulphur in the ifland of Guadaloupe, in the Weft-Indies. It is thus named as often affuming a white colour from the afhes and fulphur covering it. It empties into the river St Louis.—*ib.*

WHITE, a river of Louifiana, which joins Arkanfas river, a water of the Miffiffippi, about 10 miles above the fort, which Mr Hutchins reckons 550 computed miles from New-Orleans, and 660 from the fea. It has been navigated above 200 miles in flat-bottomed boats.—*ib.*

WHITE, a fmall river of the N. W. Territory, which purfues a north-weft, and, near its mouth, a wefterly courfe, and enters Wabafh river, 12 miles below the mouth of Chickafaw river.—*ib.*

WHITE, a river of Vermont, which falls into Connecticut river about 5 miles below Dartmouth college, between Norwich and Hartford. It is from 100 to 150 yards wide, fome diftance from its mouth. Its fource is in a fpring, which by means of Onion river, communicates with Lake Champlain. It derives its name from the whitenefs of its water.—*ib.*

WHITE *Cape*, or *Blanco*, on the weft coaft of New Mexico, is 20 leagues to the north-weft of Herradura. This cape, in lat. 10 N. bears with the ifland Canoe, at north-weft by weft and S. E. by E. and with St Luke Ifland at N. E. by N. and fouth-weft by fouth, being about 9 leagues from each.—*ib.*

WHITE *Deer*, a townfhip of Pennfylvania, fituated on Sufquehannah river.—*ib.*

WHITEFIELD, a townfhip of Pennfylvania, in Weftmoreland county.—*ib.*

WHITE *Ground*, a place in the Creek country, 10 miles from Little Tallaffee.—*ib.*

WHITEHALL, a townfhip of Pennfylvania, in Northampton county.—*ib.*

WHITEHALL, a townfhip of New York, Wafhington county, bounded foutherly by the S. bounds of the tract formerly called Skeenfborough, and northerly by the N. bounds of the county. In 1790, it contained 805 inhabitants. In 1796, 150 of the inhabitants were electors.—*ib.*

WHITE MARSH, a townfhip of Pennfylvania, Montgomery county.—*ib.*

WHITEPAINE, a townfhip of Pennfylvania, Montgomery county.—*ib.*

WHITE PLAINS, a townfhip of New York, Weft-Chefter county, bounded eafterly by Mamaroneck river, and wefterly by Bronx river. It contains 505 inhabitants, of whom 76 are electors, and 49 flaves. It is remarkable for a battle fought here between the American and Britifh forces, on the 28th of October, 1776. It is 15 miles E. by N. of Kingfbridge, 30 N. E. by N. of New York, and 125 from Philadelphia.—*ib.*

WHITE *Point*, in the ifland of Jamaica, lies eaftward of White Horfe Cliffs, about 7 leagues E. of Port Royal.—*ib.*

WHITE'S *Bay*, on the coaft of Newfoundland. N. lat. 50 17, W. long. 56 15.—*ib.*

WHITESTOWN, in Herkemer county, New York, on the fouth fide of Mohawk river, 4 miles weft of Old Fort Schuyler, and 100 weft of Albany. The compact part of this new and flourifhing town lies on one beautiful ftreet, about a mile in length, ornamented with trees. The houfes are generally furnifhed with water, conducted by pipes laid under ground, from the neighbouring hills. At prefent the court-houfe, meeting-houfe, and fchool-houfe, are combined in one building; but it is contemplated fhortly to erect feparate and handfome edifices for thefe feveral purpofes. The foil of this town is remarkably good. Nine acres of wheat in one field, yielded, on an average, 41 bufhels of wheat, of 60 lb. each, an acre. This is no uncommon crop. This town and its neighbourhood has been fettled with remarkable rapidity. All that diftrict comprehended between the Oneida Refervation, and the German Flats, and which is now divided into the townfhips of Whitef-town, Paris, and Weftmoreland, was known, a few years fince, by the name of *Whiteftown*, and no longer ago than 1785, contained two families only, thofe of Hugh White, and Mofes Foot, efquires. In 1796, there were within the fame limits, 6 parifhes, with as many fettled minifters, 3 full regiments of militia, 1 corps of light-horfe, all in uniform. In the whole, 7359 inhabitants, of whom 1190 were qualified electors.—*ib.*

WHITING, a townfhip of Vermont, in Addifon county,

county, feparated from Leicefter on the E. by Otter Creek, and has part of Orwell on the W. It contains 250 inhabitants.—*ib.*

WHITTINGHAM, a townfhip of Vermont, in the fouth-weft corner of Windham county, containing 442 inhabitants.—*ib.*

WHITSUN *Ifland*, in the South Pacific Ocean, is about 4 miles long, and 3 broad; and fo furrounded by breakers that a boat cannot land. S. lat. 19 26, W. long. 137 56. Variation of the needle in 1767, 6° E. —*ib.*

WIANDOTS, or *Wyandots*, an Indian tribe inhabiting near Fort St Jofeph, and Detroit, in the N. W. Territory. Warriors, 200.—*ib.*

WIAPOCO, or *Little Wia*, is an outlet or arm of the river Oroonoko, on the weft fide. It has many branches, which are all navigable.—*ib.*

WICKFORD, a fmall trading village in the townfhip of North Kingftown, Rhode-Ifland, and on the W. fide of Narraganfet-Bay; 24 miles S. of Providence, and 9 or 10 N. W. of Newport.—*ib.*

WIESPINCAN, a river of Louifiana, which empties into the Miffiffippi, 22 miles above the Soutoux village.—*ib.*

WICOMICO, a fmall river of Maryland, which rifes in Suffex county, Delaware, and empties into Fifhing-Bay, on the eaft fhore of Chefapeak Bay.—*ib.*

WIGHCOMICO, a fhort navigable river of Maryland, which is formed by Piles and Allen's Frefh, and, running fouthward, empties into the Patowmac, about 35 miles from its mouth. Cob Neck forms the north limit of its mouth.—*ib.*

WILBRAHAM, a townfhip of Maffachufetts, in Hampfhire county, 10 miles E. of Springfield, 30 N. E. of Hartford in Connecticut, and 89 S. W. of Bofton. It was incorporated in 1763; contains 2 parifhes, and 1555 inhabitants.—*ib.*

WILKES, a county of the upper diftrict of Georgia, feparated from S. Carolina, on the eaftward, by Savannah river, and contains 31,500 inhabitants, including 7,268 flaves. Tobacco is the chief produce of this county, of which it exported about 3000 hhds. in 1788. It is well watered, and is famous for a medicinal fpring, near its chief town, Wafhington.—*ib.*

Wilkes, a county of Morgan diftrict, in the N. W. corner of N. Carolina. It contains 8,143 inhabitants, including 549 flaves.—*ib.*

Wilkes, a poft-town and chief of the above county, 33 miles from Rockford, 45 from Morgantown, and 611 from Philadelphia.—*ib.*

WILKIE (William, D. D.), the author of an heroic poem, entitled the *Epigoniad*, was born in the parifh of Dalmeny, in the county of Weft-Lothian, on the 5th of October 1721. He was defcended of an ancient family in that county, though his father rented only a fmall farm, and was poor and unfortunate through life. He was able, however, to give his fon a liberal education; and that fon, it is faid, difcovered fo early a propenfity to the ftudy of poetry, that he began to write verfes in his tenth year.

As this wonderful prematurity of genius was never heard of during Wilkie's life, it will probably be confidered as a ftory fabricated to raife the Scottifh poet to the fame eminence with Pope, whofe verfification he is allowed to have imitated with fuccefs. We have no doubt but that Wilkie wrote in early life the defcription of a ftorm, which is publifhed in the 9th volume of the Statiftical Account of Scotland; but that he wrote it in his tenth year is not proved, and is highly improbable. The poem difplays a notion—a confufed notion indeed—of the laws of electricity, which a boy in his tenth year, and at a period when electricity was little underftood, could not have acquired.

Having learned the rudiments of the Latin tongue at the parifh-fchool of Dalmeny, young Wilkie was, at the age of thirteen, fent to the univerfity of Edinburgh, where he was foon diftinguifhed by his originality of thought, and by his rapid progrefs in erudition and fcience. Among his fellow ftudents he was moft clofely affociated with Dr Robertfon the hiftorian, Mr John Home the poet, Dr M'Ghie (A), who afterwards obtained the friendfhip of Johnfon, and became a member of the Ivy-lane Club; and a Mr Cleghorn, who promifed to be an ornament to the univerfity, in which he was afterwards a profeffor, but died before he had time to realize the fond hopes of his friends. During the courfe of his education, Wilkie became acquainted with the celebrated David Hume and Dr Fergufon, and at a later period with Dr Adam Smith, the far-famed author of "The Wealth of Nations." Of all thofe men he regarded Dr Fergufon with the greateft affection, and Dr Smith with the greateft admiration. This laft writer he confidered as equal to Robertfon and Hume in erudition, and vaftly their fuperior in originality and invention; and this opinion he cherifhed to the day of his death.

Before he had completed his education, his father died, leaving him no other inheritance than the ftock and unexpired leafe of his farm, and the care of his three fifters. Wilkie, therefore, turned much of his attention to agriculture, in which he became eminent, not merely as a theorift, but as a practical farmer. He had too much fcience to be the flave of ancient prejudice, and too much judgment to be hurried into hazardous experiments by the charms of untried fpeculation. One of his fifters being married to a fkilful, though unlettered farmer, he availed himfelf of his brother's experience; and upon the facts and maxims derived from him built a fyftem of practical farming, which fully anfwered his own expectation, and obtained the applaufe of all his neighbours.

He ftill profecuted his ftudies in the univerfity, and without ceafing to be a farmer became a preacher in the church of Scotland. For fome years this made no alteration in the mode of his living. He preached occafionally for the minifters of his neighbourhood; culti-

---

(A) According to Sir John Hawkins, this man bore arms on the fide of government at the battle of Falkirk 1745. After which, taking a degree in phyfic, he went to London in hopes of employment through the intereft of his countrymen, and perhaps in return for his loyalty. He was a learned, ingenious, and modeft man; but fo little fuccefsful in his profeffion, that he died of a broken heart, and was buried by a contribution of his friends.

vated his farm; read the classics; and, enamoured of the simple sublimity of Homer, project an epic poem on the Homeric model. The subject of his intended poem he drew from the fourth book of the *Iliad*, where Sthenelus gives Agamemnon a short account of the sacking of Thebes; and as that city was taken by the sons of those who had fallen before it, Wilkie gave to his poem the quaint title of *Epigoniad*, from the Greek word επιγονοι, which signifies *descendants*. It is not our business to write a criticism upon this poem. The subject was ill-chosen; for the learned reader has enough of the heroic ages in the immortal poems of Homer and Virgil, and in those ages the unlearned reader can feel no interest. The Epigoniad, therefore, though composed in smooth and elegant verse, with due attention to ancient manners, and constructed on the most regular plan, has fallen into neglect, from which no critic or biographer will ever rescue it.

In the year 1753, Mr Wilkie was ordained minister of Ratho, in consequence of a presentation from the Earl of Lauderdale, who knew his worth and admired his genius. Without neglecting his favourite amusements of husbandry, or the study of the belles lettres, he discharged with fidelity the duties of a Christian pastor, was famed for his original and impressive mode of preaching, and soon came to be loved as well as esteemed by his rural flock.

In the year 1757 the Epigoniad was published, the result of fourteen years study and application, which might surely have been more usefully employed on some other work; and in 1759 a second edition was called for, to which he added *A Dream in the manner of Spenser*. He was, the same year, chosen professor of natural philosophy in the university of St Andrew's; an office for which it is difficult to conceive how he could have been fitted by the study of epic poetry, and close attention to the cultivation of his farm. He was, however, a man of a vigorous mind, and we never heard that he disgraced his electors.

When he removed to St Andrew's, his whole fortune exceeded not L. 200 Sterling; a proof that his Epigoniad had not enriched him. With this sum he purchased a few acres of land in the neighbourhood of the city, carried his two unmarried sisters with him, and continued to live in the university exactly as he had lived at Ratho. In his professorial career there was nothing remarkable. He patronised genius, especially poetical genius, in the young men who attended his lectures, and by them was, of course, loved and esteemed: (See Fergusson in this *Suppl.*). In the year 1768 he published a volume of fables of no great value, previous to which the university conferred upon him the degree of D. D.; and he died, after a lingering illness, on the 10th of October 1772.

The manners of Dr Wilkie were singular, and in some respects disgusting. He has been severely blamed for his penuriousness, but, in our opinion, unjustly. His father had left him in debt, with nothing but the profits which he might make of a small farm to discharge that debt, and to support himself and three sisters. In him, therefore, rigid economy was, for many years, a virtue; and he knows little of human nature, who can blame a man for not breaking habits which it had been the duty, as well as the business of a great part of his life to form.

Amidst his most rigid and offensive economy, he was liberal in his donations to the poor.

He had been seized while minister of Ratho, with an unformed ague, of which he never got entirely rid. For this complaint he thought an extraordinary perspiration necessary, and generally slept, in winter, under twenty-four blankets. He had an utter aversion from clean linen, and has been known to bargain, when he staid a night from home, not only for the proper quantity of blankets to his bed, but also for sheets, which had been used by some other person, and rendered sufficiently dirty to please his feeling. It will easily be conceived that such a man was, to the last degree, slovenly in his dress.

Suspicions have been thrown out by his latest, and we believe his only, biographer, that Dr Wilkie's belief of the Christian religion was neither orthodox nor steady. Not having had the pleasure of his acquaintance, we cannot positively say that these suspicions are groundless; but the writer of this article has conversed much about the author of the Epigoniad with a clergyman who knew him well, and who would have been glad to accuse him of infidelity, if he could have preferred such an accusation with truth. He was a very absent man, apt to forget what he was about even when discharging the most solemn parts of his clerical duty, and used to say of himself that he never could conduct a sacrament. From this absence of mind, and those confessions of it, may have arisen the suspicion that he was not a firm believer; but no such suspicion was ever thrown out to this writer by the clergyman already referred to.

He had one very extraordinary defect in a poet: He could not read aloud the smoothest verses, so as to preserve either the measure or the sense of them. Of this Dr Anderson has produced very compete proof in his life of Wilkie, prefixed to his poetical works in the Edinburgh edition of the British Poets. With all his defects, however, and all his foibles, he was unquestionably a genius, and, we are inclined to believe, a good man.

WILKSBARRE, or *Wilksburg*, a post-town of Pennsylvania, and chief town of Luzerne county, situated on the south-east side of the east branch of the Susquehannah. It contains a court-house, gaol, and about 45 houses. It is 67 miles N. E. of Bethlehem, about the same distance above Sunbury, and 118 N. by N. W. of Philadelphia.—*Morse.*

WILLIAM, *Fort*, (now called the *Castle*) was erected on Castle Island in Boston harbour, in the reign of king William, by Col. Roemer, a famous engineer. When the British troops evacuated Boston, in March, 1776, the fortifications were blown up, but were soon after repaired. The buildings are the governor's house, a magazine, gaol, barracks, and work-shops. On this island, which contains about 18 acres of land, distant 3 miles from the town of Boston, there are a number of convicts, who are sentenced to confinement here for different periods, according to their crimes, and employed in the manufacture of nails and shoes, and guarded by a company of between 60 and 70 soldiers. The fort, which commands the entrance into the harbour, has 50 pieces of cannon mounted, and 44 others lie dismounted.—*ib.*

WILLIAMS,

WILLIAMS, a town in Northampton county, Pennsylvania.—*ib.*

WILLIAM'S *Sound, Prince*, on the north-weſt coaſt of N. America. Its E. point is in lat. 60 19 N. and long. 146 53 weſt, and Cape Elizabeth which is its weſt point, and the E. point of Cook's river, is in lat. 59 10, and long. 152 15.—*ib.*

WILLIAMSBOROUGH, a poſt-town of N. Carolina, and capital of Granville county, pleaſantly ſituated on a creek which falls into the Roanoke. It carries on a briſk trade with the back counties, and contains between 30 and 40 houſes, a court-houſe, gaol, and flouriſhing academy. It is 17 miles from Warrenton, 48 north-eaſt of Hillſborough, 56 weſt-north-weſt of Halifax, and 407 from Philadelphia.—*ib.*

WILLIAMSBURG, a county of Virginia, between York and James' rivers, and was joined in the enumeration of inhabitants, in 1790, with York county. Theſe together contain 5,233 inhabitants.—*ib.*

WILLIAMSBURGH, a townſhip of Maſſachuſetts, Hampſhire county, on the weſt ſide of Connecticut river, having Hatfield on the E. It contains a handſome Congregational church, 159 houſes, and 1,049 inhabitants. In the year 1760, this townſhip was a wilderneſs. It lies 7 miles from Connecticut river, 8 north-weſt from Northampton, and 108 weſt of Boſton.—*ib.*

WILLIAMSBURG, a poſt-town of New-York, Ontario county, ſituated on the E. ſide of Geneſſee river, near where Canaſerago creek empties into that river; 30 miles S. W. of Canandaigua, 40 N. W. of Bath, 98 N. W. of Athens or Tioga Point, and 288 N. W. of Philadelphia.—*ib.*

WILLIAMBURG, called alſo *Joneſtown*, a town of Pennſylvania, Dauphine county, at the junction of Little Swatara with Swatara river. It has a German Lutheran and Calviniſt church, and about 40 dwelling-houſes. It is 23 miles N. E. by E. of Harriſburg, and 89 north-weſt of Philadelphia.—Alſo, the name of a townſhip in Luzerne county.—*ib.*

WILLIAMSBURG, a village of Maryland, in Talbot county, 5 miles N. E. of Eaſton, and 4 N. W. of King's-Town.—*ib.*

WILLIAMSBURG, a poſt-town of Virginia, lies 60 miles eaſtward of Richmond, ſituated between two creeks, one falling into James, the other into York river. The diſtance of each landing-place is about a mile from the town. During the regal government it was propoſed to unite theſe creeks by a canal paſſing through the centre of the town; but the removal of the ſeat of government rendered it no longer an object of importance. It contains about 200 houſes, and has about 1,400 inhabitants. It is regularly laid out in parallel ſtreets, with a pleaſant ſquare in the centre of about 10 acres, through which runs the principal ſtreet eaſt and weſt, about a mile in length, and more than 100 feet wide. At the ends of this ſtreet are two public buildings, the college and capitol. Beſides theſe, there is an Epiſcopal church, a priſon, a court-houſe, a magazine, now occupied as a market, and a hoſpital for lunatics, calculated to accommodate between 20 and 30 patients, in ſeparate rooms or cells. The houſe is neatly kept, and the patients well attended; but convaleſcents have not ſufficient room for free air and exerciſe without making their eſcape. Not far from the ſquare ſtood the governor's houſe, or palace, as it was called. This was burnt during the war, while it was occupied as an American hoſpital. The houſe of the preſident of the college, occupied alſo as an hoſpital by the French army, ſhared the ſame fate. This has ſince been rebuilt at the expenſe of the French government. In the capitol is a large marble ſtatue, of Narbone Berkley, Lord Botetourt, a man diſtinguiſhed for his love of piety, literature, and good government, and formerly governor of Virginia. It was erected at the expenſe of the State, ſome time ſince the year 1771. The capitol is little better than in ruins, and this elegant ſtatue is expoſed to the rudeneſs of negroes and boys, and is ſhamefully defaced. A late act of the aſſembly authoriſes the pulling down one half of this building, to defray the charge of keeping the other half in repair. The college of William and Mary fixed here, was founded in the time of king William and queen Mary, who granted to it 20,000 acres of land, and a penny a pound duty on certain tobaccoes exported from Virginia and Maryland, which had been levied by the ſtatute of 25 Car. 2. The aſſembly alſo gave it, by temporary laws, a duty on liquors imported, and ſkins and furs exported. From theſe reſources it received upwards of 3,000l. The buildings are of brick, ſufficient for an indifferent accommodation of perhaps 100 ſtudents. By its charter, it was to be under the government of 20 viſitors, who were to be its legiſlators, and to have a preſident and ſix profeſſors, who were incorporated. It was allowed a repreſentative in the general aſſembly. Under this charter, a profeſſorſhip of the Greek and Latin languages, a profeſſorſhip of mathematics, one of moral philoſophy, and two of divinity, were eſtabliſhed. To theſe, were annexed, for a ſixth profeſſorſhip, a conſiderable donation by a Mr Boyle of England, for the inſtruction of the Indians, and their converſion to Chriſtianity. This was called the profeſſorſhip of Braſſerton, from an eſtate of that name in England, purchaſed with the monies given. A court of admiralty ſits here whenever a controverſy ariſes. It is 12 miles E. of York-Town, 60 E. of Richmond, 48 N. W. of Norfolk, and 338 S. S. W. of Philadelphia.

Leaſt heat here,	6°	0′
Mean heat,	60	8
Greateſt heat,	98	0

N. lat. 37 16, weſt long. 76 48.—*ib.*

WILLIAMSPORT, a poſt-town of Maryland, Waſhington county, on the N. ſide of Patowmack river, at the mouth of Conegocheague Creek, 8 miles S. of the Pennſylvania line, 6 ſouth-weſt of Hagerſtown, 37 N. by E. of Wincheſter, in Virginia, 28 ſouth by weſt of Chamberſburg, in Pennſylvania, and 155 W. by S. of Philadelphia.—*ib.*

WILLIAMSON, a townſhip of New-York, Ontario county. In 1796, there were 142 of its inhabitants electors.—*ib.*

WILLIAMSTOWN, a townſhip of Vermont, Orange county, on the height of land between Connecticut river and Lake Champlain, about 45 miles from the former, and 50 from the latter. It is bounded eaſtward by Waſhington, and weſtward by Northfield, and contains 146 inhabitants. Stephen's Branch, a ſtream which runs N. to Onion river, riſes in this townſhip.—*ib.*

WILLIAMSTOWN, a mountainous townſhip of Maſſachuſetts, in the north-weſt corner of the State, and in Berkſhire county, containing 1769 inhabitants. It is well watered by Hooſack and Green rivers, the former of which is here 8 rods wide. On these streams are four grist-mills, three saw-mills, and a fulling-mill. The main county road passes through it. Colonel Ephraim Williams laid the foundation of an academy several years since, and endowed it by a handsome donation of lands. In 1790, partly by lottery, and partly by the liberal donation of gentlemen in the town, a brick edifice was erected, 82 feet by 42, and four stories high, containing 24 rooms for students, a large school-room, a dining-hall, and a room for public speaking. In 1793, this academy was erected into a college, by an act of the legislature, by the name of *Williams College*, in honour to its liberal founder. The languages and sciences usually taught in the American colleges are taught here. Board, tuition and other expenses of education are very low; and from its situation and other circumstances, it is likely, in a short time, to become an institution of great utility and importance. The first public commencement was held at this college in September, 1795. In 1796, the legislature granted two townships of land to Williams College. There were, in 1796, 101 students in the four classes in this college, besides 30 pupils in the academy connected with the college. A company was incorporated the year abovementioned, to bring water in pipes into the town street. It is 28 miles north of Lenox, and 150 north-westerly of Boston.—*ib.*

WILLIAMSTOWN, a post-town and the capital of Martin county, N. Carolina, is situated on Roanoke river, and contains but few houses, besides the court-house and gaol. It is 25 miles from Blountsville, 24 from Plymouth, 55 from Halifax, and 444 from Philadelphia. —*ib.*

WILLIMANTIC, a small river of Connecticut, which runs a south-east course, and uniting with Natchaug river, forms the Shetucket at Windham.—*ib.*

WILLINGBOROUGH, a township of New-Jersey, situated in Burlington county, on Delaware river, about 14 miles from Philadelphia. It has generally a thin soil, but considerable quantities of fruits and vegetables are raised here for the Philadelphia market.—*ib.*

WILLINGTON, a township of Connecticut, in Tolland county, 6 miles east of Tolland, and 35 north-easterly of Hartford, and was settled in 1719. The lands are rough and hilly. The earthquake on sabbath evening, Oct. 29, 1727, was severely felt in this town.—*ib.*

WILLIS, a township in Chester county, Pennsylvania.—*ib.*

WILLIS *Creek*, in Maryland, falls into the Patowmack from the north at Fort Cumberland.—*ib.*

WILLIS *Island*, in the S. Atlantic Ocean, is near the north-west end of South Georgia, and has Bird Island to the north of it. S. lat. 54, west long. 38 30.—*ib.*

WILLISTON, a township of Vermont, in Chittenden county, joins Borlington on the N. W. It contains 471 inhabitants.—*ib.*

WILLOUGHBY *Bay*, near the south-east part of the island of Antigua, in the West-Indies. It is well fortified. Bridgetown lies on its north-eastern side, in St Philips parish, and is defended by Fort William. —*ib.*

WILLOUGHBY *Lake*, in Vermont, in the township of Westmore. It is about 6 miles long and one broad, and sends a stream which runs northward and empties into Lake Memphremagog, in the township of Salem. This lake furnishes fish resembling bass, of an excellent flavour, weighing from 10 to 30 pounds. People travel 20 miles to this lake, to procure a winter's stock of this fish.—*ib.*

WILLS *Cove*, on the north-east side of the isthmus of the island of St Kitts, in the West Indies, to the eastward southerly from North Friar and Little Friar Bays. —*ib.*

WILLS *Creek*, or *Caicuctuck*, a branch of Patowmack river, is 30 or 40 yards wide at its mouth, where Fort Cumberland stood. It affords no navigation as yet, and runs a short course southerly. It is 281 miles N. W. of Williamsburg, 171 from Fredericksburg, and 173 E. by N. of Alexandria.—*ib.*

WILLS-TOWN, an Indian village on the N. E. bank of Muskingum river, 45 miles from its mouth, and 117 south-westerly from Pittsburg, by the Indian path through the Indian town.—*ib.*

WILMANTON, in the State of New-York, stands on Wallkill, between Newburg and New-Brunswick. —*ib.*

WILMINGTON, one of the eastern maritime districts of N. Carolina; bounded north-east by Newbern district, south-east by the Altantic Ocean; south-west by S. Carolina; and north-west by Fayette. It comprehends the counties of Brunswick, New-Hanover, Onslow, Duplin, and Bladen. It contains 26,035 inhabitants; of whom 10,056 are slaves.—*ib.*

WILMINGTON, a port of entry and post town of N. Carolina, capital of the above district, is situated on the east side of the eastern branch of Cape Fear or Clarendon river; 34 miles from the sea, and 100 southward of Newbern. The course of the river, as it passes by the town, is nearly from north to south, and the breadth 150 yards. Opposite the town are two islands extending with the course of the river, and dividing it into three channels: they afford the finest rice fields in N. Carolina. The town is regularly built, and contains about 250 houses, a handsome Episcopal church, a court-house, and gaol. Having suffered much by two fires, one-fourth of the town, which has been rebuilt, is of brick. Its markets are well supplied with fish, and all manner of provisions. A considerable trade is carried on to the West-India Islands and the adjacent States. The exports for one year, ending the 30th of September 1794, amounted to 133,534 dollars. Those of all the other ports of the State, amounted only to 177,598 dollars. It is 90 miles south-east of Fayetteville, 192 south-south-west of Edenton, 198 north-east of Charleston, S. Carolina, and 600 south-south-west of Philadelphia. N. lat. 34 11, W. long. 78 15.—*ib.*

WILMINGTON, a township of Vermont, in Windham county, containing 645 inhabitants, who are chiefly wealthy farmers. It lies on Deerfield river, on the E. side of the Green Mountain, on the high-road from Bennington to Brattleborough, about 20 miles from each. Considerable quantities of maple sugar are made in it; some farmers make 1000 or 1400 pounds a season. The *Hay-stack*, in the north-west corner of this township, is among the highest of the range of the Green Mountains. It has a pond near the top of it, about half a mile in length, round which deer and moose are found. —*ib.*

WILMINGTON, a township of Massachusetts, in Middlesex county, 16 miles from Boston. It was incorporated

rated in 1730, and contains 710 inhabitants. Hops, in great quantities are raised in this town.—*ib.*

Wilmington, a port of entry and post-town of the State of Delaware, and the most considerable town in the State. It stands in Newcastle county, on the north side of Christiana Creek, between Christiana and Brandywine creeks, which at this place are about a mile distant from each other, but uniting below the town, they join the Delaware in one stream, 400 yards wide at the mouth. The scite of the principal part of the town is on the south west side of a hill, which rises 109 feet above the tide, 2 miles from Delaware river, and 28 southwest from Philadelphia. On the north-east side of the same hill, on the Brandywine, there are 13 mills for grain, and about 40 neat dwelling-houses, which form a beautiful appendage to the town. The Christiana admits vessels of 14 feet draught of water to the town; and those of 6 feet draught 8 miles further, where the navigation ends; and the Brandywine admits those of 7 feet draught to the mills. The town is regularly laid out in squares similar to Philadelphia, and contains upwards of 600 houses, mostly of brick, and 3,000 inhabitants. It has 6 places of public worship, viz. 2 for Presbyterians, 1 for Swedish Episcopalians, 1 for Friends, 1 for Baptists, and 1 for Methodists. Here are two market-houses, a poor-house, which stands on the west side of the town, and is 120 feet by 40, built of stone, and 3 stories high, for the reception of the paupers of Newcastle county. There is another stone building which was used as an academy, and was supported for some time with considerable reputation, but by a defect in the constitution of the seminary, or some other cause, it has, of late, been entirely neglected as a place of tuition. There are, however, nearly 300 children in the different schools in town. About the year 1736, the first houses were built at this place; and the town was incorporated a few years afterwards. Its officers are two burgesses, 6 assistants, and two constables, all of whom are annually chosen. N. lat. 39 43 18, W. long. 75 32.—*ib.*

WILMOT, a township of Nova-Scotia, Annapolis county, settled from Ireland and New-England.—*ib.*

WILSONVILLE, a town of Pennsylvania, newly laid out on the Walenpapeck, at its junction with the Lexawacsein, 120 miles north of Philadelphia. Here are already erected 14 houses, a saw and grist mill, and a large building for manufacturing sail-cloth. The creek here falls upwards of 300 feet, some say 500, in the space of a mile; for 17 miles above the falls the creek has a gentle current.—*ib.*

WILTON, a village of Charleston district, S. Carolina; situated on the E. side of Edisto river, 27 miles S. W. of Charleston.—*ib.*

Wilton, a township of New-Hampshire, Hillsborough county, S. W. of Amherst, adjoining, about 70 miles westerly of Portsmouth. It was incorporated in 1762, and contains 1105 inhabitants.—*ib.*

WIMACOMACK, a village of New-York, in Suffolk county, Long-Island; 6 miles west by south of Smithtown, and N. E. of Huntingdon, and 44 E. by N. of New-York city.—*ib.*

WINCHENDON, a post-town of Massachusetts, in Worcester county, 7 miles N. of Gardner, 35 northwesterly of Worcester, 60 north-west by west of Boston, and 370 north-east of Philadelphia. This township was formerly called *Ipswich Canada*, until it was incorporated in 1764. It is on Miller's river, and contains 950 inhabitants. This place was visited by a dreadful tornado, on the 21st of October, 1795, which did considerable damage.—*ib.*

WINCHESTER, a township of Connecticut, in Litchfield county, about 12 or 15 miles N. of Litchfield.—*ib.*

Winchester, a township of New-Hampshire, in Cheshire county, east of Hinsdale and Fort Dummer, adjoining. It is 110 miles from Portsmouth, and contains 1209 inhabitants.—*ib.*

Winchester, the chief town of Clarke county, Kentucky.—*ib.*

Winchester, or *Fredericktown*, a post-town of Virginia, and the capital of Frederick county. It is situated near the head of Opeckon Creek, which empties into Patowmack river; about 36 miles from the celebrated passage of the Patowmack through the Blue Ridge. It is a handsome flourishing town, standing upon low and broken ground, and has a number of respectable buildings; among which are a court-house, gaol, a Presbyterian, an Episcopalian, a Methodist, and a new Roman Catholic church. The dwelling houses are about 350 in number, several of which are built of stone. It is a corporation, and contains nearly 2,000 inhabitants. It was formerly fortified; but the works are now in ruins. It is 50 miles east by south of Romney, 100 north-east by north of Staunton, 110 west-north-west of Alexandria, 180 north-west of Richmond, and 192 from Philadelphia. N. latitude 39 17 30, W. longitude 78 39.—*ib.*

WIND *Gap*, a pass in the Blue Mountains in Pennsylvania; about 9 miles S. W. of Penn's Fort. Although 100 feet higher than the present bed of the Delaware, it is thought to have been formerly part of the bed of that river. The Wind Gap is a mile broad, and the stones on it such as seem to have been washed for ages by water running over them.—*ib.*

WINDHAM, a county in the south-east corner of Vermont; having the State of Massachusetts south and Connecticut river east, which divides it from New-Hampshire. It contains 22 townships, and 17,693 inhabitants. Chief towns, Newfane and Putney.—*ib.*

Windham, a county in the N. E. corner of Connecticut, having the State of Massachusetts N. and the State of Rhode Island E. It contains 13 townships, and 28,921 inhabitants, including 184 slaves. Chief town, Windham.—*ib.*

Windham, the capital of the above county, and a post-town, is situated on Shetucket river, 12 miles N. by W. of Norwich, and 31 E. of Hartford. It contains between 60 and 70 compact houses, a court house, gaol, an academy, and a Congregational church. It is 253 miles from Philadelphia. The river Willimantick from the N. W. and Natchaug from the N. meet in the northwesterly part of the township, and form the Shetucket, a pleasant river, affording plenty of fish, particularly salmon, at some seasons of the year. The township was settled from Norwich, in 1686, and was incorporated in 1702.—*ib.*

Windham, a township of New-Hampshire, Rockingham county, is about 25 miles south-west of Exeter, and 40 from Portsmouth. It contains 663 inhabitants.—*ib.*

WINDHAM, a townſhip of the Diſtrict of Maine, Cumberland county, 134 miles north of Boſton. It was incorporated in 1762, and contains 938 inhabitants. —*ib.*

WINDSOR, a townſhip of Nova-Scotia, in Hants county, near the river St Croix, which empties into the Avon. The rivers Kenetcoot and Cocmiguen (ſo called by the Indians) run through this townſhip and empty into the Avon. On theſe rivers are flouriſhing ſettlements and fertile land. Lime-ſtone and plaſter of Paris are found here. The late Potawock (ſo called by the Indians) lies between the head of St Margaret's Bay and the main road from Halifax to Windſor; the great lake of Shubenaccadie lies on the eaſt ſide of this road, about 7 miles from it, and 21 from Halifax.—*ib.*

WINDSOR, a county of Vermont, bounded N. by Orange, S. by Windham, E. by Connecticut river, and W. by Rutland and part of Addiſon county. It contains 22 townſhips, and 15,748 inhabitants.—*ib.*

WINDSOR, a poſt-town of Vermont, and capital of the above county, is ſituated on the weſt bank of Connecticut river, 18 miles N. by W. of Charleſtown, in New-Hampſhire, 45 E. by S. of Rutland, 80 N. E. of Bennington, and 255 from Philadelphia. The townſhip contains 1452 inhabitants. This, with Rutland, is alternately the ſeat of the State Legiſlature.—*ib.*

WINDSOR, a hilly townſhip of Maſſachuſetts, in Berkſhire county, 20 miles N. N. W. of Lenox, and 136 W. by N. of Boſton. The county road to Northampton paſſes through it, alſo the road from Pittsfield to Deerfield. It gives riſe to Houſatonick and Weſtfield rivers, on which are 4 ſaw-mills and 2 corn-mills. It was incorporated in 1771, and contains 916 inhabitants. In the Gore, adjoining Adams and Windſor, are 425 inhabitants.—*ib.*

WINDSOR, a conſiderable and very pleaſant town of Hartford county, Connecticut, on the weſt ſide of Connecticut river, about 7 miles northerly of Hartford. Here Windſor Ferry river, formed by the junction of Farmington and Poquabock rivers, empties into the Connecticut from the weſt. Windſor Ferry river divides the townſhip into the upper and lower pariſhes. —*ib.*

WINDSOR, a townſhip of New-Jerſey, Middleſex county, containing 2,838 inhabitants, including 190 ſlaves. —*ib.*

WINDSOR, a townſhip of Pennſylvania, York county. —*ib.*

WINDSOR, a poſt-town and the capital of Bertie county, N. Carolina; ſituated on Cuſhai river, and contains, beſides a few houſes, a court-houſe and gaol. It is 23 miles W. by S. of Edenton, 18 from Plymouth, 97 from Halifax, and 481 from Philadelphia.—*ib.*

WINDWARD *Paſſage*, a name given to a courſe from the S. E. part of the iſland of Jamaica, in the Weſt-Indies, and extending for 160 leagues to the N. ſide of Crooked Iſland in the Bahamas. Ships have often ſailed through this channel from the north part of it to the iſland of Cuba, or the Gulf of Mexico, notwithſtanding the common opinion, on account of the current, which is againſt it; that they keep the Bahama ſhore on board, and that they meet the wind in ſummer for the moſt part of the channel eaſterly, which with a counter current on ſhore puſhes them eaſily through it. —*ib.*

WINDWARD *Point*, near the eaſtern extremity of the iſland of St Chriſtopher's, is the eaſt point of Sandy-Hill Bay; about 2 miles to the W. N. W. of St Anthony's Hill Point.—*ib.*

WINEE, or *Black River*, in S. Carolina, riſes in Camden diſtrict, and running ſouth-eaſterly through Cheraws into Georgetown diſtrict, unites with Pedee river, about 3 miles above Georgetown.—*ib.*

WINES (ſee that article, *Encycl.* and *Vegetable Substances*, *Suppl.*) are ſo often adulterated with minerals prejudicial to the health, that various methods have been deviſed for detecting the adulteration. The property which liver of ſulphur (alkaline ſulphures) and hepatic air (ſulphurated hydrogen) poſſeſs of precipitating lead in a black form, has been long ago made public; and this property has been employed to determine the quality of wines by means of the *liquor probatorius Wirtembergenſis*, or Wirtemberg proving liquor. But in trying wines ſuppoſed to have been adulterated, this proof does more hurt than ſervice, becauſe it precipitates iron of the ſame colour as the pernicious lead. Many wine-merchants, therefore, of the greateſt reſpectability, rendered by theſe means ſuſpected, have been ruined.

The following is recommended by M. Hanhemann as a better teſt of ſound wines than the proving liquor of Wirtemberg. Mix equal parts of oyſter ſhells and crude ſulphur in a fine powder, and put the mixture into a crucible. Heat it in a wind furnace, and increaſe the fire ſuddenly, ſo as to bring the crucible to a white heat, for the ſpace of 15 minutes. Pulveriſe the maſs when it is cool, and preſerve it in a bottle cloſely ſtopped.

To prepare the liquor, put 120 grains of this powder, and 120 grains of cream of tartar (acidulous tartarite of potaſh), into a ſtrong bottle; fill the bottle with common water, which boil for an hour, and then let it cool; cloſe the bottle immediately, and ſhake it for ſome time: after it has remained at reſt to ſettle, decant the pure liquor, and pour it into ſmall phials capable of holding about an ounce each, firſt putting into each of them 20 drops of muriatic acid. They muſt be ſtopped very cloſely with a piece of wax, in which there is a ſmall mixture of turpentine.

One part of this liquor, mixed with three parts of ſuſpected wine, will diſcover, by a very ſenſible black precipitate, the leaſt traces of lead, copper, &c. but will produce no effect upon iron, if it contains any of that metal. When the precipitate has fallen down, it may ſtill be diſcovered whether the wine contains iron, by ſaturating the decanted liquor with a little ſalt of tartar (tartareous acidulum of potaſh), by which the liquor will immediately become black. Pure wines remain clear and bright after this liquor has been added to them.

WINHALL, a townſhip of Vermont, in Bennington county, about 25 or 30 miles N. E. of Bennington. It contains 155 inhabitants.—*Morse.*

WINNIPISEOGEE, a lake in New-Hampſhire, and the largeſt collection of water in the State. It is 22 miles in length from S. E. to N. W. and of very unequal breadth, but no where more than 8 miles. Some very long necks of land project into it; and it contains ſeveral iſlands, large and ſmall, and on which rattle-ſnakes are common. It abounds with fiſh from

6 to 20 pounds weight. The mountains which surround it, give rise to many streams which flow into it; and between it and the mountains, are several lesser ponds, which communicate with it. Contiguous to this lake are the townships of Moultonborough on the N. W. Tuftonborough and Wolfborough on the N. E. Meredith and Gilmantown on the S. W. and a tract of land, called the Gore, on the S. E. From the S. E. extremity of this lake, called Merry Meeting Bay, to the north-west part called Senter Harbour, there is good navigation in the summer, and generally a good road in the winter; the lake is frozen about 3 months in the year, and many sleighs and teams, from the circumjacent towns, cross it on the ice. Winnipiscogee river conveys the waters of the lake into Pemigewasset river, through its eastern bank at New-Chester.—*ib.*

WINLAND, a country accidentally discovered by Biron or Biorn, a Norman, in 1001; supposed to be a part of the island of Newfoundland. It was again visited, and an intercourse opened between it and Greenland. In 1221, Eric, bishop of Greenland, went to Winland to recover and convert his countrymen, who had degenerated into savages. This prelate never returned to Greenland; nor was any thing more heard of Winland for several centuries.—*ib.*

WINLOCK, or *Wenlock*, a township of Vermont, in Essex county, west of Minehead.—*ib.*

WINNEBAGO, a lake of the N. W. Territory; west of Michigan Lake, and south-west of Bay Puan, into which it sends its waters. It is about 15 miles long from east to west, and 6 wide. It receives a large stream from the south-west called Crocodile river. Fox river enters it from the west, and by it, through Ouisconsing river, has communication with Mississippi river, interrupted by a portage of only 3 miles. The centre of the lake lies in lat. about 43 30 N. and long. 88 10 W.—*ib.*

WINNEBAGOES, an Indian nation inhabiting round the lake of the same name, who can furnish 2 or 300 warriors. Their town stands on an island at the E. end of the lake, of about 50 acres extent, and distant from Bay Puan 35 miles, according to the course of the river. The town contains about 50 houses, which are strongly built with pallisades. The land adjacent to the lake is very fertile, abounding spontaneously with grapes, plums, and other fruit. The people raise a great quantity of Indian corn, beans, pumpkins, squashes, melons, and tobacco. The lake abounds with fish, and in the autumn or fall, with geese, ducks, and teal; and are very fat and well flavored by feeding on wild rice, which grows plentifully in these parts. Mr Carver thinks from the result of his inquiries of the origin, language, and customs of this people, that they originally resided in some of the provinces of Mexico, and migrated to this country about a century ago. Their language is different from any other yet discovered; and they converse with other nations in the Chippeway tongue.—*ib.*

WINNIPEG, or *Winnepeek*, a lake in Upper Canada, north-west of Lake Superior. It lies between 50 30 and 54 32 N. lat. and between 95 50 and 99 30 W. long. It is 217 miles long, including Baskescoggan or Play-Green Lake, its northern arm; and is 100 miles broad from the Canadian House on the E. side to Sable river on the west side. It receives the waters of a number of small lakes in every direction, and exhibits a number of small isles. The lands on its banks are said, by Carver and other travellers, to be very fertile, producing vast quantities of wild rice, and the sugar-tree in great plenty. The climate is considerably more temperate here than it is upon the Atlantic coast, 10° farther southward.—*ib.*

WINNIPEG, *Little*, a lake which lies west of the former, and has communication with Lake Minitoba, on the S. which last sends the waters of both into Winnipeg Lake, in an E. N. E. course. It is 80 miles long and 15 broad. Fort Dauphin is seated on a lake contiguous, on the west, whose waters empty into this lake. Dauphin Fort lies in lat. 51 46 N. and long. 100 54 W.—*ib.*

WINNIPEG *River*, runs north-west into the lake of its name. It is the outlet of the waters of a vast chain of lakes; the chief of which are La Plue and Lake of the Woods. The lat. of the Provision Store, at the bottom of the river, is 50 33 12 N.—*ib.*

WINNSBOROUGH, a post-town, and the capital of Fairfield county, S. Carolina; situated on a branch of Wateree Creek, which empties into the river of that name. Here are about 25 houses, a handsome court-house, a gaol, and a college called Mount Zion college, which is supported by a respectable society of gentlemen, and has been long incorporated. The institution flourishes, and bids fair for usefulness. It is 30 miles north-north-west of Columbia, 130 from Charleston, and 708 from Philadelphia.—*ib.*

WINSLOW, a post-town of the District of Maine, Lincoln county, situated on Kennebeck river; 18 miles north of Harrington. Fort Halifax was built at this place in 1754, on the point of land at the confluence of Sebasticook and Kennebeck rivers. This town is 88 miles N. by E. of Portland, 211 in a like direction from Boston, and 559 from Philadelphia. It was incorporated in 1771, and contained, in 1790, 779 inhabitants, and in 1797, about 1500.—*ib.*

WINTERHAM, a place in Amelia county, Virginia. Black lead is found here; but no works for its manufacture are established: those who want it go and procure it for themselves.—*ib.*

WINTHROP, a post-town of the District of Maine, Lincoln county, between Androscoggin and Kennebeck rivers, about 10 miles from each; 5 miles easterly of Monmouth; 10 west by south of Hallowell, now Harrington court-house, 57 north of Portland, 185 from Boston, and 529 from Philadelphia. The township in which it stands, was incorporated in 1771, and contains 1240 inhabitants.—*ib.*

WINTHROP'S *Bay*, on the north coast of the island of Antigua. Maiden Island, a small isle south south-west of Long Island is due east of the south-east point of this bay.—*ib.*

WINTON, a county of Orangeburg district, S. Carolina.—*ib.*

WINTON, a post-town of North-Carolina, and capital of Hartford county, on the S. E. side of Chowan river, a few miles below the place where Meherrin and Nottaway join their waters. It has a court-house and gaol, and a few compact houses. It is 12 miles from Murfreesborough, 15 from the Bridge on Bennet's Creek, 130 S. S. E. of Petersburg, in Virginia, and 434 from Philadelphia.—*ib.*

WINYAW *Bay*, on the coaft of South-Carolina, communicates with the ocean 12 miles below George-town.—*ib.*

WISCASSET, a port of entry and poft-town of the Diftrict of Maine, Lincoln county, on the weft fide of Sheepfcut river, 10 miles S. E. of New-Milford on the E. fide of Kennebeck river, 13 north-weft of Bath, 56 north-weft of Portland, 178 N. E. by N. of Bofton, 525 from Philadelphia, and 1513 from Sunbury in Georgia. It is a part of the townfhip of Pownalborough, and is very flourifhing. It contains a congregational church, and about 120 houfes. Its navigation is greater in proportion to its fize and number of inhabitants than any part of Maffachufetts. A gazette is publifhed here, and the county courts are held in it. Wifcaffet Point is 3 leagues from Crofs river. The exports for one year, ending the 30th of Sept. 1794, amounted to 23,329 dollars.—*ib.*

WITCHARN *Bay*, is within the great found in the Bermudas Iflands, in the Weft-Indies; fituated at the E. part of the bottom or S. part of the Sound, having two fmall iflands at the mouth of it.—*ib.*

WOAHOO, one of the Sandwich Ifles, in the North Pacific Ocean, 7 leagues north-weft of Morotoi Ifland. It is high land, and contains 60,000 inhabitants; and has good anchoring ground, in lat. 21 43 N. and long. 157 51 W.—*ib.*

WOAPANACHKY, the name of the Delaware nation, in their language.—*ib.*

WOAPO, one of the Ingraham Iflands, lefs in fize than Chriftiana. The body of it lies in lat. 9 27 S. It bears north-weft by weft, about 20 leagues from Refolution Bay. It was called *Adams*, by Capt. Ingraham; and a fmall ifland to the fouthward of it he called *Lincoln*. Capt. Roberts afterwards difcovered them and named them from his fhip and fchooner; the larger *Jefferfon*, and the leffer *Refolution*.—*ib.*

WOBURN, a townfhip of Maffachufetts, in Middlefex county, 10 miles north of Bofton. It was incorporated in 1642 by the name of *Wooborne*, and was till then known by the name of *Charleftown Village*. It contains 1727 inhabitants.—*ib.*

WOLCOTT, a townfhip of Vermont, in Orleans county, fouth of Craftfbury, containing 32 inhabitants. La Moille river runs N. weftward through it.—*ib.*

WOLF, a fmall boatable river of Tenneffee, which runs wefterly into Miffiffippi river, about 19 miles fouth of Hatchy river, and 55 from Reelfoot. It is 50 yards wide feveral miles from its mouth, which is very near the fouth-weft corner of the State, in lat. 35.—*ib.*

WOLFBOROUGH, a townfhip of New-Hampfhire, Strafford county, on the E. fide of Winnipifiogee Lake, and contains 447 inhabitants. It contains fome fine farms, and particularly that which formerly belonged to Gov. Wentworth.—*ib.*

WOLVES *Iflands* lie near Campo Bello Ifland, on the eafternmoft coaft of the Diftrict of Maine. Between thefe the foundings are from 50 to 100 fathoms. N. lat. 44 48, W. long. 66 40. From Grand Mannan Ifland to Wolves Iflands the courfe is N. E. by N. 3 leagues.—*ib.*

WOMELDORF, a poft-town of Pennfylvania, in Berks county, fituated on the weft fide of a fmall ftream which falls into Tulpehocken Creek. It contains about 40 houfes, and a German Lutheran and Calvinift church. It is 68 miles north-weft of Philadelphia.—*ib.*

WOODBRIDGE, a poft-town of New-Jerfey, Middlefex county, on the great road from New-York to Philadelphia, on a ftream which falls into Arthur Kull, above Amboy. It is about 3 miles N. by W. of Amboy, 10 fouth-wefterly of Elizabeth-Town, and 70 N. E. of Philadelphia. The townfhip contains 3550 inhabitants, including 256 flaves.—*ib.*

Woodbridge, a townfhip of Connecticut, New-Haven county, about 7 miles north-weft of New-Haven city.—*ib.*

WOODBURY, a townfhip of Vermont, in Caledonia county, 15 or 20 miles weft-north-weft of Barnet.—*ib.*

Woodbury, a poft-town of New-Jerfey, and capital of Gloucefter county, fituated near a fmall ftream, which empties into the Delaware below Red Bank. It contains about 80 houfes, a handfome brick court-houfe, a Quaker meeting-houfe, and an academy. Several of the houfes are neat and handfome. It is 9 miles fouth of Philadelphia, and 11 north-eaft of Swedefburg. Alfo, the name of a townfhip of Pennfylvania, in Huntingdon county.—*ib.*

Woodbury, a townfhip of Connecticut, in Litchfield county, 8 miles fouth of Litchfield. It was fettled in 1672.—*ib.*

WOOD *Creek*, a fluggifh ftream which rifes in the high lands, a little eaft of Fort Edward, on Hudfon's river; and after running 25 miles, falls into the head of Lake Champlaine at Skenefborough. It has a fall at its mouth, otherwife it is navigable for batteaux for 20 miles up to Fort Anne.—*ib.*

Wood *Creek* runs weftward, and empties into Lake Oneida.—*ib.*

WOOD-cuts are engravings on wood, commonly on box, which, in many cafes, are ufed with advantage inftead of copper-plates. The art of cutting or engraving on wood is undoubtedly of high antiquity; for Chinefe printing is a fpecimen of it. (See China, n° 127. *Encycl.*) Even in Europe, if credit be due to Papillon, this art was practifed at a period confiderably remote; for he mentions eight engravings on wood, entitled, "A reprefentation of the warlike actions of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, prefented, and humbly offered, to the moft holy father, Pope Honorius IV. by us Alexander Alberic Cunio Chevalier, and Ifabella Cunio, &c." This anecdote, if true, carries the art of cutting in wood back to 1284 or 1285; for Honorius occupied the papal throne only during thefe two years. Even this is not the remoteft period to which fome have carried the art in Europe; for the ufe of feals or fignets being of very high antiquity, they imagine that the invention of wood-cuts muft be coeval with them. The fuppofition is certainly plaufible, but it is not fupported by proof. The earlieft impreffion of a wooden-cut, of which we have any certain account, is that of St Chriftopher carrying an infant Jefus through the fea, in which a hermit is feen holding up a lantern to fhew him the way; and a peafant, with a fack on his back, climbing a hill, is exhibited in the back ground. The date of this impreffion is 1423.

In the year 1430 was printed at Haarlem, "The hiftory

Wood-cuts. history of St John the evangelist and his revelation, represented in 48 figures in wood, by Lowrent Janson Cotter;" and, in 1448, Jorg Schappf of Augsburg cut in wood the history of the Apocalypse, and what was called *The poor man's bible.* (See Engraving, *Encycl.* page 668.)

A folio chronicle, published 1493 by Schedal, was adorned with a vast number of wood-cuts by William Plydenwurff and Michael Wolgemut, whose engravings were greatly superior to any thing of the kind which had appeared before them. Wolgemut was the preceptor of Albert Durer, whose admirable performances in this department of art are justly held in the highest esteem even at the present day.

About this period it became the practice of almost all the German engravers on copper to engrave likewise on wood; and many of their wood-cuts surpass in beauty the impressions of their copper-plates. Such are the wood-cuts of Albert Aldtorfer, Hisbel Pen, Virgil Soles, Lucas van Cranach, and Lucas van Lyden, the friend and imitator of Albert Durer, with several others.

It appears that the Germans carried this art to a great degree of perfection. Hans or John Holbien, who flourished in 1500, engraved the *Dance of Death*, in a series of wooden-cuts, which, for the freedom and delicacy of execution, has hardly been equalled, and never surpassed.

Italy, France, and Holland, have produced many capital artists of this kind. Joan. Tornæsium printed a bible at Lyden, in 1554 (a copy of which we have seen), with wooden-cuts of excellent workmanship. Christopher Jegher of Antwerp, from his eminence in the art, was employed by Rubens to work under his inspection, and he executed several pieces which are held in much estimation; the character of these is boldness and spirit.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of the *chiaro scuro*. Carpi was an Italian, and of the 16th century; but the Germans claim the invention also, and produce in evidence several engravings by Mair, a disciple of Martin Schoen, of date 1499. His mode of performing this was very simple. He first engraved the subject upon copper, and finished it as much as the artists of his time usually did. He then prepared a block of wood, upon which he cut out the extreme lights, and then impressed it upon the print; by which means a faint tint was added to all the rest of the piece, excepting only in those parts where the lights were meant to predominate, which appear on the specimens extant to be whitened with white paint. The drawings for this species of engraving were made on tinted paper with a pen, and the lights were drawn upon the paper with white paint.

There is, however, a material difference between the *chiaro scuros* of the old German masters and those of the Italians. Mair and Cranach engraved the outlines and deep shadows upon copper The impression taken in this state was tinted over by means of a single block of wood, with those parts hollowed out which were designed to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, Wood-cuts. to cut the outline on one block of wood, the dark shadows upon a second, and the light shadows, or half tint, upon a third. The first being impressed upon the paper, the outlines only appeared: this block being taken away, the second was put in its place, and being also impressed on the paper, the dark shadows were added to the outlines; and the third block being put in the same place upon the removal of the second, and also impressed upon the paper, made the dim tints, when the print was completed. In some instances, the number of blocks were increased, but the operation was still the same, the print receiving an impression from every block.

In 1698, John Baptist Michel Papillon practised engraving on wood with much success, particularly in ornamental foliage and flowers, shells, &c. In the opinion, however, of some of the most eminent artists, his performances are stiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be said to have been wholly lost, when it was lately re-invented by Mr Bewick of Newcastle.

This eminent artist was apprentice to Mr Bielby, an engraver on metal of the very lowest order, who was seldom employed in any thing more difficult than the cutting of the face of a clock. Application having been made to this man for a wood-cut or two of the most trifling description, the job was given to Thomas Bewick; by whom it was executed in such a manner, that Mr Bielby, who was accustomed to employ his apprentices in such work, advised him to prosecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and sawing the wood on which he was to work into the requisite thickness, proceeded to improve upon his own discoveries, without assistance or instruction of any kind. When his apprenticeship expired, he went to London, where the obscure wood-engravers of the time wished to avail themselves of his abilities, while they were determined to give him no insight into their art. He remained some years in London; and during that time, if we mistake not, received from the *Society for the Encouragement of Arts, &c.* a premium of considerable value for the best engraving in wood. Returning to Newcastle, he entered into copartnership with his old master; and established his reputation as an artist by the publication of his admirable History of Quadrupeds. This was followed by his History of Birds, of which only one volume has yet (1800) appeared.

John Bewick, brother to Thomas, learned the art of him, and practised it for several years in London with great applause. His abilities, however, though respectable, were not, by the best judges, deemed so brilliant as his brother's; and owing to bad health, and the nature of his connection with the booksellers and others, he seems not to have advanced the art beyond the stage at which he received it. He died, three or four years ago, at Newcastle.

Mr Nesbit, who executed the admirable Hudibras published by Vernor and Hood (A), and Mr Anderson,

---

(A) The designs were by Thornton; and the cuts from them have been compared to Holbein's far-famed Dance of Death.

od-cuts. fon, whofe beautiful cuts adorn the poem entitled *Grove Hill*, were the next, and hitherto have been the laft of Thomas Bewick's pupils, who have appeared before the public as artifts. By thefe gentlemen we are authorized to fay, that the method practifed by the ancient engravers on wood, whofe works are ftill admired, muft have been different from that of Bewick and his pupils. What that method was feems to be altogether unknown. Papillon, who writes the beft hiftory extant of the art, gueffes indeed in what manner the old engravers proceeded fo as to give to their works the fpirit and freedom for which they are famed; but that his gueffes are erroneous feems evident from the ftiffnefs of his own works. The principal characteriftic in the mechanical department of the productions of the ancient mafters is the croffing of the black lines, which Papillon has attempted with the greateft awkwardnefs, though it feems to have been accomplifhed by them with fo much eafe, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this crofs hatching is fo difficult and unnatural, that it may be confidered as impracticable (B).

The engravers of Bewick's fchool work on the end of the wood which is cut acrofs the trunk of the tree, in pieces of the proper thicknefs. As wood-cuts are generally employed in the printer's prefs amidft a form of types, this thicknefs muft be regulated by the height of the types with which they are to be ufed. The tools employed are nearly the fame with thofe ufed in copperplate engraving, being only a little more deep, or lozenge, as engravers call it. They muft have points of various degrees of finenefs for the different purpofes to which they are applied, fome of them being fo much rounded off at the bottom as to approach to the nature of a goodge, whilft others are in fact little chiffels of various fizes. Thefe chiffels and goodges, to which every artift gives the fhape which he deems moft convenient, are held in the hand in a manner fomewhat different from the tool of the engraver on copper, it being neceffary to have the power of lifting the chips upwards with eafe. To attempt a defcription of this in writing would be in vain; but it is eafily acquired, we are told, by practice.

The pupils of the fchool of Bewick confider it as quite improper to fpeak of his invention as a revival of the ancient art. Some old prints, it is true, have the appearance of being executed in the fame way with his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the prefent art by what has been done, but by what may be done; and that remains yet to be fhewn. The art is in its infancy; and thofe who are difpofed to compare it with the art of engraving on copper, ought to look back to the period when copperplate engraving was of as recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that he was able to imitate on copper plates the wood cuts of Albert Durer; and Papillon is highly indignant that there fhould have been perfons fo very blind as to miftake the copies for the originals. If copper has its advantages over wood in point of delicacy and minutenefs, wood has, in its turn, advantages not inferior in regard to ftrength and richnefs. Thofe prints which were executed under the aufpices of Titian and Rubens, will always remain a monument of the fpirit and vigour natural to wood-engraving; and if there be not found in them all the attention to *chiaro fcuro*, which the prefent age demands, it muft not be attributed either to defect in the art, or to want of abilities in the artifts, but to the tafte of the times when *chiaro fcuro* was little underftood. It remains for fome enterprifing artift to fhew that the vigour of the ancient art may be attained by the prefent one, and at the fame time to add to that vigour thofe gradations of fhade which are fo much admired in good copperplates. As there feems to be a more perfect, or at leaft a more pleafant black produced by wood than by copperplate printing, and certainly a more perfect white (c), who will fay that any intermediate fhade whatever may not be produced by wood-cuts? To attempt this on a fmall fcale would indeed be vain, becaufe the flighteft variation, produced by a little more or lefs ink, or a harder preffure in printing, bears fuch a proportion to a very fhort line, as muft neceffarily render the attempt abortive.

Wood-cuts, || Woods.

Wood-engraving, therefore, muft always appear to difadvantage while it is confined to fmall fubjects, and will never reach its ftation *as a fine art*, till thofe who are engaged in its cultivation improve upon the difcoveries of one another, and apply to fubjects to which it is properly adapted. As an *economical art* for illuftrating mechanics and other fubjects of fcience, it is too little employed even in its prefent ftate.

The works of Bewick and his pupils which have hitherto been publifhed, are not numerous. Befides his quadrupeds and birds, the Hudibras by Nefbit, and the Grove Hill by Anderfon, which have been already noticed, we are acquainted with none but the following:—Goldfmith's *Traveller* and *Deferted Village* with elegant plates, all by Thomas Bewick, except one or two which were executed by John; Somerville's *Chace* by the fame artifts, executed in a ftyle of elegance which perhaps has never been furpaffed; a View of St Nicholas's Church, Newcaftle, 15 inches long, by Mr Nefbit, who received for it a filver medal from the Society for the Encouragement of Arts, and an honorary letter from the Society of Antiquaries.

WOODFORD, a county of Kentucky, on Ohio river, between Kentucky and Licking rivers. Chief town, Verfailles.—*Morse*.

WOODFORD, a townfhip of Vermont, eaft of Bennington, adjoining. It contains 60 inhabitants.—*ib.*

WOOD *Ifland*, on the fea-coaft of the Diftrict of Maine, 5 leagues north-eaft of Cape Porpoife, and fouth-weft by fouth 4 leagues of Richman's Ifland.—*ib.*

WOODS, *Lake of the*, the moft northern in the

United

(B) Mr Nefbit has indeed introduced fomething of it into two or three of his pieces, merely to fhew that he *could* do it; but fo great was the labour, and fo little the advantage of this improvement, if fuch it can be called, that probably it will not be attempted again.

(c) The parts of the print intended to be white are not even touched by the wood-block.

United States, is ſo called from the large quantities of wood growing on its banks; ſuch as oak, pine, fir, ſpruce, &c. This lake lies nearly eaſt of the ſouth end of Winnipeg Lake, and is ſuppoſed to be the ſource or conductor of one branch of Bourbon river. Its length from eaſt to weſt is ſaid to be about 70 miles; and in ſome places it is 40 miles wide. Other accounts ſay it is 36 leagues in length. The Killiſtinoe Indians encamp on its borders to fiſh and hunt. This lake is the communication between the lakes Winnipeg, Bourbon, and Lake Superior.—*ib.*

WOODSTOCK, one of the principal towns of Windſor county, Vermont. It has a court-houſe and about 50 dwelling-houſes. It lies north-weſt of Windſor, adjoining, and contains 1665 inhabitants. Waterquechie river paſſes through the centre of the town, on the banks of which ſtand the meeting-houſe and court-houſe.—*ib.*

Woodstock, a townſhip of New-York, in Ulſter county, bounded eaſterly by Kingſton, Hurley and Marbletown, and weſterly by Delaware river. It contains 1025 inhabitants, including 15 ſlaves. In 1796, according to the State cenſus, 160 of the inhabitants were qualified electors.—*ib.*

Woodstock, a ſmall town of N. Carolina, on the E. ſide of Pamplico river.—*ib.*

Woodstock, a poſt-town of Virginia, ſeat of juſtice and capital in Shenandoah county. It contains between 60 and 70 houſes, a court-houſe and gaol. The inhabitants are moſtly Germans and their deſcendants. It is 12 miles from Straſburg, 40 from Rockingham court-houſe, and 222 from Philadelphia.—*ib.*

Woodstock, a conſiderable and pleaſant townſhip of good land, in the N. E. corner of Connecticut, Windham county, divided into 3 pariſhes. This townſhip, which is 7 miles ſquare, was granted by the general court of Maſſachuſetts, 7th Nov. 1783, and was ſettled by 39 families from Roxbury in 1688. This town remained under the juriſdiction of Maſſachuſetts till about the year 1760, ſince which time it has been conſidered as belonging to Connecticut. It is 66 miles S. W. of Boſton, 45 N. E. of Hartford, 22 S. W. of Worceſter, 33 N. W. of Providence, and about the ſame diſtance N. of Norwich.—*ib.*

WOODSTOWN, a poſt-town of New-Jerſey, Salem county, and contains about 40 or 50 houſes. It is 12 miles N. by E. of Salem, 31 north by weſt of Bridgetown, and 26 S. S. W. of Philadelphia.—*ib.*

WOODY *Point*, one of the limits of Hope Bay, on the north-weſt coaſt of North-America, as Breaker's is the other. It is in about lat. 50 N. and long. 128 weſt. —*ib.*

WOOL-combing, a well known operation, which, when performed by the hand, is laborious, tedious, and expenſive. The expenſe of it through all England has been calculated at no leſs a ſum than L 800,000; and to leſſen this expenſe, the Rev. Edmund Cartwright of Doncaſter in Yorkſhire bethought himſelf ſome years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following deſcription:

Plate L. Fig. 1. Is the crank laſher. A is a tube through which the material, being formed into a ſliver, and ſlightly twiſted, is drawn forward by the delivering rollers. B, a wheel faſt upon the croſs-bar of the crank. C, a wheel, on the oppoſite end of whoſe axis is a pinion working in a wheel upon the axis of one of the delivering rollers.

Note, When two or more ſlivers are required, the cans or baſkets, in which they are contained, are placed upon a table under the laſher (as repreſented at D), which by having a ſlow motion, twiſts them together as they go up.

Fig. 2. Is the circular clearing comb, for giving work in the head, carried in a frame by two cranks. Fig. 3. The comb-table, having the teeth pointing towards the centre, moved by cogs upon the rim, and carried round upon trucks, like the head of a windmill. *a*, *b*, the drawing rollers. *c*, *d*, callender, or conducting rollers.

Note, Underneath the table is another pair of rollers, for drawing out the backings.

In the above ſpecification, we have omitted the frame in which the machine ſtands, the wheels, ſhafts, &c. Had theſe been introduced, the drawing would have been crowded and confuſed; beſides, as matters of information, they would have been unneceſſary, every mechanic, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if for particular nice work, goes through three operations, otherwiſe two are ſufficient: the firſt operation opens the wool, and makes it connect together into a rough ſliver, but does not clear it. The clearing is performed by the ſecond, and, if neceſſary a third operation. A ſet of machinery, conſiſting of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 240lb. in twelve hours. As neither fire nor oil is neceſſary for machine-combing, the ſaving of thoſe articles, even the fire alone, will, in general, pay the wages of the overlooker and children; ſo that the actual ſaving to the manufacturer is the *whole* of what the combing coſts, by the old imperfect mode of hand-combing. Machine-combed wool is better, eſpecially for machine-ſpinning, by at leaſt 12 *per cent.* being all equally mixed, and the ſlivers uniform, and of any required length.

WOOLWICH, a townſhip of Glouceſter county, New-Jerſey.—*Morſe.*

Woolwich, a townſhip of Lincoln county, Diſtrict of Maine, on the E. ſide of Kennebeck river, S. of Pownalborough, containing 797 inhabitants.—*ib.*

WOONSOKET *Falls*, on Blueſtone river, in Smithfield townſhip, Rhode-Iſland.—*ib.*

WORCESTER, a large and populous county of Maſſachuſetts. It contains 50 townſhips, 53 Congregational churches, 510,236 acres of unimproved land, and 207,430 under cultivation, and 56,807 inhabitants. It is about 50 miles in length, from north to ſouth, and about 40 in breadth; bounded ſouth almoſt equally by the States of Connecticut and Rhode-Iſland, and north by the State of New-Hampſhire. On the eaſt it is bounded chiefly by Middleſex county, and weſt by Hampſhire county.—*ib.*

Worcester, a poſt-town of Maſſachuſetts, and capital of the above county. It is the largeſt inland town of New-England, and is ſituated about 45 miles weſt of Boſton, 52 north-eaſt of Spring-field, and 299 north east of Philadelphia. The public buildings in this town are two Congregational churches, a court-house, and a strong stone gaol. The inhabitants, upwards of 2000 in number, have a large inland trade, and manufacture pot and pearl ash, cotton and linen goods, besides some other articles. The compact part of the town contains about 150 neat houses, situated in a healthy vale, principally on one street. Printing in its various branches, is carried on very extensively in this town by Isaiah Thomas, Esq. who in the year 1791, printed two editions of the Bible, the one the large royal quarto, the first of that kind published in America, the other a large folio, with 50 copper-plates, besides several other books of consequence. His printing apparatus consists of 10 printing-presses, with types in proportion; and he is now making preparations for the printing of Bibles of various smaller kinds. His printing apparatus is reckoned the largest in America. This township, part of what was called *Quinsigamond* by the Indians, was incorporated in 1684; but being depopulated by Indian hostilities, the first town-meeting was held in 1722. It is proposed to open a canal between Providence, in Rhode-Island, and this town. N. lat. 42 23, W. long. 71 44.—*ib.*

Worcester, a township of Pennsylvania, in Montgomery county.—*ib.*

Worcester, the south-easternmost county of Maryland, having Somerset county and Chesapeak Bay on the west, Sinepuxent Bay on the east, which opens to the N. Atlantic Ocean, and Accomac county, in Virginia, on the south. It is well watered by Pocomoke, Assatigul, and St Martin's river. It contains 11,640 inhabitants, including 3836 slaves. Chief town, Snowhill.—*ib.*

Worcester, a township of Vermont, in the easternmost part of Chittenden county, abount 25 miles east of Burlington.—*ib.*

WORTHINGTON, a post-town of Massachusetts, in Hampshire county, 19 miles west by north of Northampton, 25 east by south of New-Lebanon, in New-York State, 120 westerly of Boston, and 289 from Philadelphia. It was incorporated in 1768, and contains 1116 inhabitants.—*ib.*

WRENTHAM, the *Wollomonuppouge* of the Indians, a considerable township of Norfolk county, Massachusetts, on the post-road from Boston to Providence, 27 miles south-south-west of Boston, and 18 north-east of Providence, containing 1767 inhabitants; formerly a part of Dedham, incorporated in 1661. There is a curious cavern in this town, called *Wampom's Rock*, from an Indian family of that name who lived in it for a number of years. It is about 9 feet square, and 8 feet high, lessening from the centre to about four feet. It is surrounded by broken rocks, and now serves as a shelter for cattle and sheep, as do several others here, formerly inhabited by Indians.—*ib.*

WRIGHTSBOROUGH, a small settlement or village on Little river, a branch of the Savannah, about 30 miles from Augusta. It was settled by Joseph Mattock, Esq. one of the Friends, who named it after Sir James Wright, then governor of Georgia, who promoted its establishment.—*ib.*

WRIGHTSTOWN, in Buck's county, Pennsylvania, 4 miles N. of Newtown, and 4 W. of Delaware river.—*ib.*

WYACONDA, a river of Louisiana, which falls into the Mississippi 34 miles below Riviere du Moins, —*ib.*

WYALUSING, a township of Pennsylvania, Luzerne county.—*ib.*

WYALUXING *Creek*, in Luzerne county, Pennsylvania, falls into the East Branch of Susquehannah river from the north-eastward, and north-westward of Meshoppen Creek, which is 33 miles south-east of Tioga Point.—*ib.*

WYMOA *Road*, in the North Pacific Ocean, a place of anchorage at Atooi Island, one of the Sandwich Islands, in lat. 21 57 north, and long. 159 47 west. It is at the south-west side, and about 6 miles from the west end of the island. The island is about 10 leagues long, and 25 leagues north-west of Woahoo Island.—*ib.*

WYONDOTTS, or *Wiandats*, an Indian nation residing near Fort Detroit, in the neighbourhood of the Ottawas and Putawatimes, whose hunting grounds are about Lake Erie. The number of warriors, 20 years ago, were, Wyondotts 250, Ottawas 400, Putawatimes 150. Another tribe of the Wyondotts live near Sandusky, among the Mohickons and Caghnawagas, who together have 300 warriors. At the treaty of Greenville, in consequence of lands ceded to the United States, the latter agreed to pay them a sum in hand, and in goods to the value of 1000 dollars a year forever.—*ib.*

WYNTON, the chief town of Hertford county, Edenton district, North-Carolina.—*ib.*

WYOMING, a general name formerly given to a tract of country in Pennsylvania, situated on Susquehannah river, above Wilksbarre. In the year 1778, the settlement which was known under this name, consisted of 8 townships, each containing 5 miles square, settled from Connecticut, and originally under its jurisdiction, and produced great quantities of grain of all sorts, fruit, hemp, flax, &c. inhabited by about 1000 families, who had furnished the continental army with near 1000 soldiers, besides various supplies of provisions, &c. In the month of July, all these flourishing settlements were reduced by the Indians and tories to a state of desolation and horror, almost beyond description. In the vicinity of Wyoming is a bed of coal, of the open burning kind, which gives a very intense heat. Wyoming Falls lie about 2 miles above Wilksbarre, and 8½ miles above Nantikoke Falls. N. lat. 41 14, W. long. 75 53. —*ib.*

WYONOKE *Creek*, in N. Carolina, lies within or about lat. 36 30 N. The charter of Carolina, in 1664, extended the bounds eastward as far as the north end of Currituck Inlet, upon a straight line westerly to this creek.—*ib.*

WYTHE, a county of Virginia, said to be 120 miles in length, and nearly 50 in breadth; bounded north by Kanhaway, and south by the state of North Carolina. Its population in 1790 was included in Montgomery county. There are lead mines in this county, on the Great Kanhaway, 25 miles from the line of N. Carolina, which yield from 50 to 80lbs. pure lead from 100lbs washed ore, but most commonly 60 to 100. Two of them are worked by the public; the best of which is 100 yards under the hill; and although there are not more than 30 labourers generally employed, they might employ 50 or 60 to advantage. The labourers cultivate their own corn. Twenty, Worcester. twenty-five and sometimes sixty tons of lead have been extracted from these mines in a year. Chief town, Evansham. The court-house is on the post-road from Richmond to Danville, in Kentucky, 301 miles from the former, and 323 from the latter. It is 46 miles from Montgomery court-house, 57 from Abingdon, and 454 from Philadelphia. A post-office is kept here.—*ib.*

X.

Xagua, ‖ Xalisco.

XAGUA, a harbour on the S. E. coast of the island of Cuba, and one of the finest ports in the West-Indies. It lies between the Islands of Pines, or Pinez, and Spirito Santo.—*Morse.*

XAINTES, Santos, or *All Saints Islands*, so named from their being discovered on that Holy Day, by the Spaniards, on the S. E. side of the island of Gaudaloupe, and in its jurisdiction. The most westerly of these three isles is called Terre de Bas, or the Low Island, and the most easterly Terre de Haut, or the High Island. The third, which lies exactly in the middle between the other two, is little other than a barren rock, and helps to form a very good harbour.—*ib.*

XALISCO, a province of New-Spain, and the most southerly on the coast of Guadalajara audience. It is bounded S. and W. by the South Sea; E. by Guadalajara Proper, and Mechoacan, and divided from Chiametlan, on the N. by a narrow slip of land belonging to Guadalajara, extending into the sea. It is not above 150 miles in extent either way. It has silver mines, and abounds with Indian wheat, but has few cattle. The oil of the *Infernal Fig-tree*, as the Spaniards call it, is brought from this province. It is said to be efficacious in dissolving tumors, expelling of wind, and all cold humours, by anointing the belly, and taking a few drops of it in a glass of wine, as also by clysters. It is also said to cure ulcers in the head, and deafness. The Indians are numerous here, and are reckoned braver and more polite than their neighbouring countrymen. The Xalisco, an ancient city, is the capital, yet the most considerable place in it is Compostella.—*ib.*

Xarayes, ‖ Xeres.

XARAYES, *Laguna de los*, a large lake of Paraguay, in S. America, formed by the river Paraguay, in its course from north to south.—*ib.*

XERES *de la Frontera*, a town in the southernmost part of Zacatecas, a province of Guadalajara audience, in New Spain, in N. America. It is garrisoned for defending the mines against the hostile Indians.—*ib.*

Y.

Yabaque, ‖ Yadkin.

YABAQUE, one of the Lucayos or Bahama Islands, situated south-west of Meguana Island. N. lat. 22 30.—*Morse.*

YADKIN, a considerable river of N. Carolina, which rises in the Alleghany Mountains, running E. about 60 miles, then turning to the S. S. E. passes the Narrows, a few miles above Rocky river; thence directing its course through Montgomery and Anson counties, enters S. Carolina. It is about 400 yards broad where it passes Salisbury, but it is reduced between 2 hills, about 25 miles to the southward of that town, to the width of 80 or 100 feet. For 2 miles it is narrow and rapid, but the most narrow and most rapid part is not above half a mile in length. In this narrow part, shad are caught in the spring of the year, by hoop nets, in the eddies, as fast as the strongest men are able to throw them out. Perhaps there is not in the United States a more eligible situation for a large manufacturing town. Boats with 40 or 50 hogsheads pass easily from these Rapids to Georgetown. The late war, by which N. Carolina was greatly convulsed, put a stop to several iron-works. At present there are 4 or 5 furnaces in the State that are in blast, and a proportionable number of forges. There is one in Guilford county, one in Surry, and one in Wilkes, all on the Yadkin. From the mouth of Rocky River to the ocean, the stream assumes the name of *Great Pedee*.—*ib.*

Yagarchoca, ‖ Yago.

YAGARCHOCA, a lake of Quito, within the limits of the jurisdiction of San Miguel de Ibarra. It is famous for having been the sepulchre of the inhabitants of Otabalo, when taken by Huayna Capac, the 12th Inca; who, instead of rewarding their magnanimity with clemency, was irritated at the noble resistance which they made against his army, ordered them all to be beheaded, and their bodies to be thrown into the lake; hence its name, which signifies a lake of blood.—*ib.*

YAGO, *St*, or *St James*, an ancient town on the N. side of St Domingo Island, founded before 1504, and the country round is reckoned as healthy as any in the island. It is situated on the high road from La Vega to Daxavon; 10 leagues west by north of the former, and 28 easterly of the latter, and about 10 from the anchoring-place of St Yague, and nearly as far from

Port

Port de Plate. It ſtands on the northern ſide of the river Yaqui, in a ſavannah commanding the river. The town is open, and regularly laid out, and contains above 600 houſes. It is 52 leagues N. N. W. of St Domingo city, 34 weſt by north of the bottom of Samana Bay, and 22 N. W. of Cotuy. The territory of St Yago, or Jago, contains 28,000 ſouls, and is very fertile in mines. The ſand of Green and Yaqui rivers is mixed with gold. Mercury is found at the head of the latter river, and copper is alſo found in this territory. The tree, guatapana, which retains its Indian name, is found here. It bears a ſort of grain or pod, from which is extracted a very fine black dye.—*ib.*

YAGUACHE, a lieutenancy of Guayaquil juriſdiction, in South-America. It lies at the mouth of the river of the ſame name, which empties into that of Guayaquil on the ſouth ſide, and has its ſource from the ſkirts of the Cordilleras, ſouth of the river Bamba. Within its juriſdiction are 3 towns; the chief of which is that where the cuſtom-houſe is erected, and called San Jacint de Yaguache; the 2 others are Nauſa and Antonche. It produces wood, cocoa, cattle, and cotton.—*ib.*

YAMACRAW, the ancient Indian name of the ſpot where Savannah, in Georgia, is erected.—Alſo the name of a tribe of the Creek Indians.—*ib.*

YAQUE, *Port St*, vulgarly called *Old Port*, a ſmall anchoring place on the N. ſide of the iſland of St Domingo; ſituated between Padrepin on the weſt, and Macoris Point on the eaſt.—*ib.*

YAQUI, *Grand*, or *Monte Chriſt River*, a river of the north part of the iſland of St Domingo, which runs a weſt-north-weſt courſe, and empties into the Bay of Monte Chriſt. It might be aſcended in canoes or ſmall boats, for 15 leagues, were it not for the limbs of trees which lodge in it. All its numerous branches are from the ſouthward.—*ib.*

YARDSLEY's *Ferry*, on Delaware river, is 3 miles north-weſterly of Trenton, in New-Jerſey, and 5 below M'Crankey's Ferry.—*ib.*

YARI, a town in Amazonia, South-America, at the head of a branch of Amazon river, ſouth-weſterly from Macapa.—*ib.*

YARMOUTH, a poſt-town of Maſſachuſetts, Barnſtable county, on the neck of the peninſula of Cape-Cod, 4 miles E. of Barnſtable, 12 E. by S. of Sandwich, 110 ſouth-weſt of Boſton, and 427 from Philadelphia. The townſhip extends from ſea to ſea. It was incorporated in 1639, and contains 2,678 inhabitants.—*ib.*

YARMOUTH, a townſhip of Nova-Scotia, in Queen's county, ſettled by New-Englanders. It lies at the head of a ſhort bay, 8 miles ſouth-eaſt of Cape St Mary.—*ib.*

YARUQUI, a plain 4 leagues north-eaſt of the city of Quito, and 249 toiſes lower than it. Near it is a village of the ſame name. This ſpot was pitched upon as the baſe of the whole operations for meaſuring the length of an arch of the meridian, by Ulloa.—*ib.*

YAZOO *River*, in Georgia Weſtern Territory, conſiſts of 3 large branches which run a ſouthern courſe, and near its mouth theſe unite and purſue a ſouth-weſt courſe a few miles, and the confluent ſtream enters the eaſtern bank of the Miſſiſſippi, by a mouth upwards of 100 yards wide; according to Mr Gauld, in lat. 32 37 N. and by Mr Purcel, in 32 28.—*ib.*

YAZOO *Cliffs*, or *Aux Cotes*, lie 7½ miles from the river Yazoo, and 39¾ miles from Louſa Chitto, or Big Black river.—*ib.*

YBAGUE, a city of New-Granada, in Terra Firma, South-America.—*ib.*

YCA, or *Valverde*, or the *Green Vale*, from a valley of the ſame name planted with vines, which is 6 leagues long, and produces plenty of wine. It is about 41 miles ſouth-eaſt of Piſco, in Peru, and is inhabited by 500 Spaniards. It is a beautiful and rich town, having a large church, 3 convents, and an hoſpital. About 6 leagues from the town is its port, called Puerto Quemada.—*ib.*

YCAQUE, or *Icaco*, the northern point of the bay of Mancenilla, in the iſland of St Domingo.—*ib.*

YLO, a port of Peru, in Los Charcos, convenient for loading and unloading, in lat. 18 S. The town of the ſame name, lies about a quarter of a league to the windward of the river, and is inhabited by Indians. Frezier calls it *Hilo*.—*ib.*

YOHOGANY, the principal branch of Monongahela river, called alſo *Youghiogeny*, and *Yoxhiogeni*, purſues a north-weſterly courſe, and paſſes through the Laurel Mountain, about 30 miles from its mouth; is, ſo far, from 300 to 150 yards wide, and the navigation much obſtructed in dry weather by rapids and ſhoals. In its paſſage through the mountain it makes very great falls, admitting no navigation for 10 miles, to the Turkey-foot. Thence to the Great Croſſing, about 20 miles, it is again navigable, except in dry ſeaſons, and at this place is 200 yards wide. The ſources of this river are divided from thoſe of the Patowmack, by the Alleghany Mountain. From the falls, where it interſects the Laurel Mountain, to Fort Cumberland, the head of the navigation to the Patowmack, is 40 miles of very mountainous road. The country on this river is uneven, but in the vallies the ſoil is extremely rich. Near to Pittſburg the country is well peopled, and there, as well as in Redſtone, all the comforts of life are in the greateſt abundance. This whole country abounds with coal, which lies almoſt on the ſurface of the ground.—*ib.*

YONKERS, a townſhip of New-York, in Weſt Cheſter county, bounded eaſterly by Bronx river, and weſterly by the county of York and Hudſon's river. It contains 1125 inhabitants, of whom 139 are electors, and 170 ſlaves.—*ib.*

YONKERS, a poſt-town of New-York, 114 miles from Philadelphia.—*ib.*

YORK, a river of Virginia, which takes its riſe near the Blue Ridge, and empties into the Cheſapeak, a little to the S. of Mobjack Bay. At York-Town it affords the beſt harbour in the State, which will admit veſſels of the largeſt ſize. The river there narrows to the width of a mile, and is contained within very high banks, cloſe under which the veſſels may ride. It has 4 fathoms water at high tide, for 20 miles above York, to the mouth of Poropotank, where the river is a mile and a half wide, and the channel only 75 fathoms, paſſing under a very high bank. At the confluence of Pamunky and Mattapony it has but 3 fathoms depth, which continues up Pamunky to Cumberland, where the width is 100 yards, and up Mattapony to within 2 miles

 miles of Frazer's Ferry, where it becomes 28½ fathoms deep, and holds that about 5 miles.—*ib.*

York, a river of York county, Diſtrict of Maine, which runs up 7 or 8 miles, and affords a tolerable harbour for veſſels under 200 tons. The rocks, however, render it ſomewhat difficult and hazardous for ſtrangers.—*ib.*

York, a maritime and populous county of the Diſtrict of Maine, bounded E. and N. E. by Cumberland, S. by the ocean, W. by New-Hampſhire, from which it is ſeparated by Salmon Fall River, and N. by Canada. It is well watered by Saco, Mouſom, and other ſtreams, and is divided into 27 townſhips, and contains 28,821 inhabitants. Chief town, York.

York, a poſt-town of the Diſtrict of Maine, in York county, 9 miles N. E. of Portſmouth, in New-Hampſhire, 20 S. of Wells, 48 S. by W. of Portland, 75 from Boſton, and 421 from Philadelphia. N. lat. 43 16. It is a port of entry and capital of the county. The river of its name empties into York harbour at the town. It is navigable for veſſels of 250 tons. About a mile from the ſea is a wooden bridge acroſs the river, 270feet in length, which was erected in 1761. Before the war, 25 or 30 veſſels were employed in the Weſt-India trade, and coaſting buſineſs, but their veſſels were taken or deſtroyed, and little marine buſineſs is now done, except that a ſmall fiſhery is ſupported. This townſhip was ſettled in 1630, and called *Agamenticus*, from the hill of that name which is a noted land-mark for mariners. In 1640, Sir Ferdinand Gorges incorporated a great part of it by the name of *Georgiana*. In the year 1692, the Indians took the town by ſurpriſe, and burnt moſt of the houſes, and 150 perſons were killed or captivated. It contained, according to the cenſus of 1790, 2900 perſons. Fiſh of various kinds frequent the rivers and ſhores of the ſea contiguous. In a calm ſeaſon, in the ſummer, one may ſtand on the rocks of the ſhore, and catch them, in the ſea, with a line, or even with an angling rod, and a fathom or two of line.—*ib.*

York, a county of Pennſylvania, bounded E and N. E. by Suſquehannah river, which ſeparates it from Lancaſter and Dauphine counties, and S. by the State of Maryland. It contains 29 townſhips, and 37,747 inhabitants.—*ib.*

York, a poſt-town and capital of the above county, ſituated on the eaſt ſide of Codorus Creek, which empties into the Suſquehannah. It contains about 500 houſes, ſeveral of which are of brick. The town is regularly laid out; the public buildings are a court-houſe, a ſtone gaol, a record-office, handſomely built, an academy, a German Lutheran, a German Calviniſt, a Preſbyterian, Roman Catholic, and Moravian church, and a Quaker meeting houſe. It is 22 miles W. S. W. of Lancaſter, 51 N. W. by N. of Hartford, in Maryland, 199 N. E. of Staunton, in Virginia, and 88 W. of Philadelphia.—*ib.*

York, a county of S. Carolina, in Pinckney diſtrict; bounded E. by Catawba river, N. by the State of North-Carolina; S. by Cheſter county, and W. by Broad River, which divides it from Spartanburg, and is one of the moſt agreeable and healthy counties in the State, and well watered by Catawba and Broad rivers, and their tributaries. It contains 6604 inhabitants, of whom 5652 are whites, and 923 ſlaves. Here are extenſive iron-works. This county ſends three repreſentatives and one ſenator to the State Legiſlature.—*ib.*

York, a county of Virginia, bounded north by York river, which divides it from Glouceſter county, ſouth by Warwick; eaſt by Elizabeth City county, and weſt by that of James City. It contains 5233 inhabitants, of whom 2760 are ſlaves.—*ib.*

York, or *Yorktown*, a port of entry and poſt-town of Virginia, and capital of York county. It is agreeably ſituated on the ſouth ſide of York river, where the river is ſuddenly contracted to a narrow compaſs, oppoſite to Glouceſter, and a mile diſtant, where there is a fort fronting that on the York ſide, about 11 miles weſt by ſouth of Toes Point, at the mouth of the river. The banks of the river are very high, and veſſels of the greateſt burden may ride cloſe under them with the greateſt ſafety. It contains about 60 or 70 houſes, a gaol, an Epiſcopal church, and a tobacco ware-houſe. In 1790, it contained 661 inhabitants, of whom 372 were ſlaves. Its exports, in the year 1794, amounted to 71,578 dollars. It will ever be famous in the American annals for the capture of Lord Cornwallis and his army by the combined force of the United States and France, which took place on the 19th of October, 1781. It is 12 miles E. by S. of Williamſburg, 21 N. W. of Hampton, 72 E. S. E. of Richmond, and 350 S. S. W. of Philadelphia. N. lat. 37 22 30, W. long. 76 52. —*ib.*

York, a town of Upper Canada, ſituated on the north-weſtern ſide of Lake Ontario, and is deſigned to be the future ſeat of government of that province. The public buildings are erecting. It is 40 miles N. by W. of Niagara Fort, and 120 W. S. W. of Kingſton. N. lat. 43 57, W. long. 80 35.—*ib.*

York *Bay* is 9 miles long, and 4 broad, and ſpreads to the ſouthward before the city of New-York. It is formed by the confluence of Eaſt and Hudſon's rivers, and emboſoms ſeveral ſmall iſlands, of which Governor's Iſland is the principal. It communicates with the ocean through the *Narrows*, between Staten and Long Iſlands, which are ſcarcely 2 miles wide. The paſſage up to New-York, from Sandy Hook, the point of land that extends furtheſt into the ſea, is ſafe, and not above 20 miles in length. The common navigation is between the eaſt and weſt banks, in about 22 feet water. The light-houſe at Sandy-Hook is in lat. 40 30 N. and long. 74 2 W.

York *Fort*, on the S. W. ſhore of Hudſon's Bay, at the mouth of Port Nelſon river, is 160 miles weſterly of Severn Houſe. N. lat. 57 1 51, W. long. 92 46 40. —*ib.*

York *Iſle*, or *Iſlands*, lie in S. lat. 50 37, about 50 leagues from the coaſt of Patagonia, in South-America, and are inhabited. Trinity Iſle lies due eaſt of them, near the main land.—*ib.*

York *Ledge*, on the coaſt of the Diſtrict of Maine. From York Harbour to York Ledge, the courſe is S. E. 2 leagues.—*ib.*

York *Minſter*, on the S. coaſt of the iſland Terra del Fuego, is 19 leagues at E. S. E. from Gilbert Iſland. S. lat. 55 26, W. long. 70 25.—*ib.*

York *Road*, or *Bay*, in the Straits of Magellan, in S. America, is 10 miles from Cape-Croſs Tide. S. lat. 53 39, W. long. 73 52.—*ib.*

YORKTOWN, a townſhip of New-York, Weſt-Cheſter county, bounded weſterly by the town of Cortland, and northerly by Dutcheſs county. In 1790, it contained 1609 inhabitants, including 40 ſlaves. In 1796, according to the State cenſus, there were 210 of the inhabitants electors.—*ib.*

YUCATAN, one of the ſeven provinces of the audience of Mexico, in New Spain. The Britiſh had a right to cut logwood and carry it away, by the treaty of 1783, in the tract between Rio Honde and Balize rivers.—*ib.*

YUNA, a river of the iſland of St Domingo, which runs an E. S. E. and E. courſe, and empties into the W. end of the Bay of Samana. It riſes near Monte Chriſt river. It is navigable no farther than Cotuy, 13 leagues from its mouth.—*ib.*

Z.

ZACATECAS, a province of New-Spain, bounded by New Biſcay on the N. by Panuco on the E. Mechoacan, Guadalajara, and Chiametlan, on the S. and by part of Chiametlan and Culiacan on the W. It is well inhabited, and abounds with large villages. The mines here are reckoned the richeſt in America.—*ib.*

Zacatecas, the capital of the above province, ſituated under the tropic of Cancer, 40 leagues N. of Guadalajara, and 80 N. W. of Mexico. Its garriſon conſiſts of about 1000 men, and there are about 800 families of ſlaves, who work in the mines and other laborious work. N. lat. 23 29, W. long. 103 20.—*ib.*

ZACATULA, a ſmall ſeaport-town of the province of Mechoacan, ſituated at the mouth of the river of the ſame name, on the coaſt of the Pacific Ocean. N. lat. 17 22, W. long. 104 58.—*ib.*

ZACHEO, or *Deſechio*, a ſmall iſland, 8 or 9 leagues to the N. E. by N. of Mona, between the iſland of St Domingo and that of Porto Rico. It is nothing more than a green mountain, 800 or 1000 yards long.—*ib.*

ZAMINY, in the language of Bengal, ſecurity.

ZAMORA, a city of Peru, in S. America, 200 miles ſouth of Quito, which is pretty large, and the houſes well built of timber and ſtone. The church and convent of Dominicans, are both elegant ſtructures. There are ſeveral gold mines in the neighbourhood of the city, but few of them are worked. S. lat. 4 10, W. long. 77 5.—*Morſe.*

ZAPOTECHAS, a river of New-Spain which runs north-eaſtward into the Gulf of Mexico. A fort of the ſame name ſtands on the N. W. bank of the river, about 250 miles S. E. from the city of Mexico.—*ib.*

ZELITO, or *Ziltio*, one of the forts for the protection of the harbour of Carthagena, on the N. coaſt of S. America.—*ib.*

ZEMINDARS, the great landholders of Bengal. This is the original ſenſe of the word; but it is now more ſtrictly applicable to thoſe who have their title conſtituted or confirmed by a patent or charter from government, by which they hold their lands or Zemindaries upon certain conditions. As far as can be aſcertained from the narrations of hiſtory, it appears that, in times prior to the irruptions of the Mahomedans, the rajahs who held their reſidence at Delhy, and poſſeſſed the ſovereignty of Hindoſtan, deputed officers to collect their revenues (Kherâje), who were called in the Indian language *Choudheries*. The word *Zemindar* is Perſian, and that language can have had no currency in the countries of India, until it was introduced by the people of Perſia. When the Emperor Shehâb-ul-Dien Ghory conquered the empire of Hindoſtan (A), he left Sultan Cutub-ul-Dien to be his viceroy at Delhy, and adminiſter the government of Hindoſtan. From that time the cuſtoms and practices of the Mahomedans began gradually to be eſtabliſhed in India; their armies were ſent into the countries of the reduced Rajahs, under the command of Omrahs, in order to preſerve the conqueſt; and lands were allotted to them to defray the expenſe. From hence aroſe the ſyſtem of Jaghiredarry in Hindoſtan. But when theſe Omrah Jaghiredars had eſtabliſhed their own ſtrength, ſeveral of them rebelled againſt the imperial authority, and aſpired at the crown. Thus circumſtanced, the emperors, in order to obviate theſe miſchiefs, thought it would be more politic to commit the management of the country to the native Hindoos, who had moſt diſtinguiſhed themſelves by the readineſs and conſtancy of their obedience to the ſovereign power.

In purſuance of this plan, diſtricts were allotted to numbers of them under a reaſonable revenue (Jummah Monâſib), which they were required to pay in money to the governors of the provinces, deputed from the Emperor. And in caſe any one of the Omrahs or provincial governors ſhould ſwerve from his allegiance, the Zemindars of that country were to exert themſelves in ſuch a manner as ſhould check rebellion, and reſtore good government. For this purpoſe, grants of Zemindary were ſeverally conferred upon ſuch of the Hindoos as were obedient; deſcribing their apportionment of the country; and every perſon who had received a grant under the authority of the crown was thereby fully inveſted with the functions of Zemindar.

The functions of a Zemindar are, 1ſt, The preſervation and defence of their reſpective boundaries from traitors and inſurgents; 2dly, The tranquillity of the ſubjects, the abundance of cultivators, and increaſe of his

(A) This event took place towards the cloſe of the 12th century. N. B. *Kherâje* ſignifies ſpecifically the tribute paid by a conquered country.

Zemindars.

his revenue. 3dly, The puniſhment of thieves and robbers, the prevention of crimes, and the deſtruction of highwaymen. The accompliſhment of theſe objects is conſidered in the royal grant as the diſcharge of office to the ſovereign; and on that account the word *office* (Khidmut) is employed in the Dewanny Sunnud for a Zemindary.

It was a rule in the times of the ancient emperors, that when any of the Zemindars died, their effects and property were ſequeſtrated by the government. After which, in conſideration of the rights of long ſervice, which is incumbent on ſovereigns, and elevates the dignity of the employer, Sunnuds for the office of Zemindary were granted to the children of the deceaſed Zemindar; and no other perſon was accepted, becauſe the inhabitants could never feel for any ſtranger the attachment and affection which they naturally entertain for the family of their Zemindar, and would have been afflicted if any other had been put over them. For this reaſon, the emperors, conſidering it as a means of conciliating the minds of the people, graciouſly fixed and confirmed the children of the deceaſed Zemindar in the office of their fathers and grandfathers, by iſſuing new ſunnuds to transfer the poſſeſſion to them. By degrees Zemindaries became truly heritable property, which, however, could be transferred by gift or ſale from one family to another. They could likewiſe be forfeited to the ſovereign, by the Zemindar's deviating from his allegiance, neglecting to pay his tribute, or to diſcharge the duties of his ſtation.

It is univerſally known, ſays Sir Charles Rouſe Boughton, that, when the three provinces of Bengal, Bahar, and Oriſſa, were ceded to the Britiſh Eaſt-India Company, the country was diſtributed among the Zemindars and Talookdars (ſee that article in this Vol.), who paid a ſtipulated revenue, by twelve inſtalments, to the ſovereign power or its delegates. They aſſembled at the capital in the beginning of every Bengal year (commencing in April), in order to complete their final payments, and make up their annual accounts; to ſettle the diſcount to be charged upon their ſeveral remittances in various coins for the purpoſe of reducing them to one ſtandard, or adjuſt their concerns with their bankers; to petition for remiſſions on account of ſtorms, drought, inundation, diſturbances, and ſuch like; to make their repreſentations of the ſtate, and occurrences of their diſtricts: after all which they entered upon the collections of the new year; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely cloſed the accounts of the preceding year, ſo that they might not encroach upon the new rents, to make up the deficiency of the paſt. Our author proves, we think completely, the right of the Zemindars to transfer their poſſeſſions, either by inheritance to their children, or, with the conſent of the ſovereign, to other families; and he argues ſtrenuouſly and ſucceſsfully againſt the bad policy, as well as injuſtice, of interfering with thoſe rights, as long as the Zemindars diſcharge the duties of their ſeveral ſtations.

Zemindars, ‖ Zoneſhio.

ZINOCHSAA, the original name of a river of New-York, which runs through Onondago, the chief town of the Six Nations.—*Morse.*

ZITAR, a town of Terra Firma, S. America, near to and ſouth from the head of the Gulf of Darien.—*ib.*

ZOAR, a plantation in Berkſhire county, Maſſachuſetts, containing 78 inhabitants.—*ib.*

ZONCOLCUCAN, mountains in Guaxaca, in New-Spain, which give riſe to Papalo-apain or Alvarad river.—*ib.*

ZONESHIO, the chief town of the Seneca Indians, 2 miles N. of Seneca Lake.—*ib.*

APPENDIX.

APPENDIX.

THE importance of every invention which tends to facilitate Navigation is fuch as to entitle it to be recorded for the benefit of mankind, particularly in Commercial Nations. In this view the accounts of the Artificial Horizon and the New Log are prefented to our readers from the Specifications of the Patents obtained by Chefter Gould, the Inventor of the *Artificial Horizon*. He fays, " My invention confifts in applying a fluid or fluids coloured, or otherwife, to the quadrant or fextant, fo as to obtain a level for the purpofe of taking the altitudes of celeftial and other fubjects, on land or water, without the affiftance of the natural horizon. This I perform in the manner following: that is to fay, I make a circular tube or ring of brafs, or of other proper fubftance, from two to three inches in diameter, or more or lefs, as convenience may direct, in which I fit four tranfparent glaffes, directly oppofite to, and parallel with, each other, fo that the furfaces of the fluid contained in the tube may be diftinctly feen by the obferver. The infide of this tube, which is to contain the fluid, may be equal in area to a tube of about one-fourth part of an inch in diameter, or even more, and when in ufe fhould be about half filled with fome tranfparent fluid, and it fhould be fixed to a fmall apparatus made of brafs or other proper fubftance, with fuch joints and adjuftments as are neceffary to bring it to its true pofition on the quadrant or fextant.

" The artificial horizon, reprefented in the annexed drawing, I confider to be moft proper for general ufe.

" Fig. A, in the drawing (fee Appendix, Plate III.), reprefents the whole inftrument with the artificial horizon put together; *m*, reprefents the fcrew which binds the cramp *n* to the frame of the quadrant or fextant, fo that the ring or tube of the artificial horizon will ftand directly behind the fore horizon glafs. The pofition of the tube or ring ought to be fuch, that its plane will be parallel to the plane of the quadrant or fextant, and fo alfo that the centre of its glaffes and the hole of the forefight vane of the quadrant or fextant, which is intended to be ufed, fhould form a line parallel to the chord of the arch, and to the plane of the quadrant or fextant at the fame time. Its true pofition on the quadrant or fextant being obtained, and the ring or tube being filled as is above defcribed up to the centre of its glaffes, and the quadrant or fextant being held in a vertical pofition, the furface of the fluid may be brought to form a perfect level with the eye of the obferver. This being done, the object whofe altitude is to be taken is then reflected down to this fluid level, in the fame manner as when altitudes are taken by a fea horizon.

" The whole inftrument may be varied in its form, fcale and proportion, the tube may be filled with mercury, but I prefer a tranfparent fluid; and, in order to retard the too fudden motion of the fluid, I make an adjuftment in the bottom of the tube (either fixed or moveable) by which the motion of the fluid is obftructed and regulated at pleafure. I have in fome inftances ufed coloured glaffes, but for general ufe I prefer the plain; in either cafe the furfaces fhould be well ground and finely polifhed. I have alfo ufed two tubes or rings, fo placed, that, when the inftrument is in ufe, the level is formed by an apparent contact of one of the furfaces of the fluid in each tube, but I think a fingle tube or ring to be much preferable.

" I prefer the artificial horizon made and ufed as above defcribed, but it may be fo conftructed as to be connected with a telefcope, fuch as is frequently applied to quadrants or fextants, by which means the furfaces of the fluid, and their contact with the image of the fun or any other body, may be more exactly determined, and this may be effected whether the inftrument is intended to be fitted up with two rings or with one only. As the form of the telefcope and of the artificial horizon as well as the mode of connecting them together admit of great variety, I inftance the following examples; that is to fay,

"The firft example fhall be where only one ring or tube is ufed. In this cafe I make the tube of fuch a figure, that one pair of the glaffes occupy the field of the telefcope, between which glaffes one of the furfaces of the fluid appears, and the other furface of the fluid is put fo much out of the axis of the telefcope, as not to obftruct the light from the object glafs, and by placing a horizontal wire, or by drawing a horizontal line acrofs one of the glaffes, the inftrument being previoufly adjufted, and fo held or placed, that the furface of the fluid in the tube between the glaffes and the wire or line is made to correfpond. The image of the fun or other object may be brought to touch the wire or line at the fame time by moving the index of the quadrant or fextant, and the altitude may be read off upon the arch as in common cafes.

" The fecond example fhall alfo be with one tube or ring only, and where both the furfaces of the fluid fhall appear as in the field of the telefcope. In this cafe, I cut off one half of the object glafs of the telefcope commonly ufed, fuppofing it to be divided by a line parallel to the plane of the inftrument, and inftead of the part taken away I place half of another object glafs, whofe focus is equal to one half of the focus of the original object glafs, and I encreafe the diftance between the furfaces of the fluid to twice the focal diftances of the original glafs, and by placing one furface of the fluid in the field of the telefcope, as in the firft example, and the other furface in the axis of the telefcope produced, the inftrument being adjufted, that furface of the fluid neceffarily placed behind the object glafs will appear to meet the furface of the fluid placed in the field of the telefcope, and to which the image of the fun can be made to coincide as in the firft example.

" The laft example fhall be where two tubes or rings are ufed. In this cafe I place one of the rings or tubes as in the firft example, that is to fay: one of the furfaces of the fluid in the field of the telefcope, and the other out of the axis of the telefcope and towards the object glafs, and I place the fecond ring or tube with one furface.

face in the field of the telescope as near to the first as possible, and the other surface of the second ring or tube out of the axis and towards the eye-glass of the telescope, the instrument being adjusted, and held or placed, so that the two surfaces placed in the field and both brought into contact with the wire or horizontal line, the image of the sun or other object may be made to coincide, and the altitude read as in the two preceding examples.

"Although the foregoing description of the artificial horizon is agreeable to the form in which I now make it, and which in my opinion is the best, yet there are other forms in which it may be made so as to produce nearly the same effect, for a fluid will become level in a tube made in the form of a square, parallelogram, or triangle, or any other form, but a circular tube being more easily made, I give it the preference; and notwithstanding I fix the ring of the artificial horizon at the back-side of the fore horizon glass of the quadrant or sextant, it being suited to the use of both these instruments, yet a good effect may be produced by fixing it to the other parts of these instruments, provided the surfaces of the fluid are distinctly seen by the observer, either directly or by reflection."

The new log for ascertaining a ship's distance at sea, for which Mr Gould has also obtained a patent, consists of a rotator or adjustable fly, connected by a line or chain, with a register which may be kept on board the vessel. The fly is composed of four vanes or wings placed both angularly and conically, so as to produce a rotary motion round the centre piece adjusted by a regulator. "This fly (says the inventor) on which accuracy of measurement by the log wholly depends, is composed of regular figures, such as planes and squares, which admit of the greatest uniformity of workmanship; and its essential parts, together with the angular position of the vanes, admit of strict examination, by the application of instruments in common use, such as the square, the compasses, and parallel rulers, by which very trifling errors may be easily discovered, without the trouble of experience by water. The general form of this fly being conical, it is not liable to obstructions at sea, from sea weeds, or other floating substances. It is also detached from the register for purposes hereafter mentioned. By the conical position of the vanes, I mean that position which is caused by moving their broadest ends from the centre in a direction with their planes, while their narrow ends remain fixed; and by the angular position I mean, that position which is caused by separating the broad ends of the vanes from the centre, (and consequently from each other), in a direction at right angles with the former position, while the narrow ends remain fixed, as in Fig. 1, in the drawing hereto annexed, (see Plate I.); or, in other words, the conical position of the vanes determines the distance between *a* and *b*, in the same figure; and their angular position determines the distance between *c* and *d*, in the same figure. The conical position of the vanes being varied, increases or diminishes the rotary power or strength of action of the fly, and their angular position being varied, increases or diminishes the number of its revolutions made in any given distance. The fly is constructed in manner following; the centre piece, or virtual axis, has at its head end an eye-hole, or other convenience for fastening the line to it, and the other end terminating in a screw, of sufficient length to vary the adjustment of the fly, so as to answer such purposes as it is intended for. It passes through a collar, having a smooth hole through its centre, sufficient to receive the axis upon which it should turn freely, and to which it is secured by a collet and pin. This collar must have the same number of flats or sides as the number of vanes intended for it; and it must terminate conically towards its head. The regulator should have the same number of sides with the former, and should also terminate conically from its base, answering to the conical form of the fly. It has a tapped hole through its centre, to fit the screw on the end of the axis, on which it should move uniformly the whole length of the screw. The vanes are to be attached by their narrow ends to the sides or flats of the collar, by screws or otherwise, having in each of them a slit or opening, to admit the screws which bind them to the regulator, as in Fig. 1, in the same drawing. I make a scale, which I graduate into sundry parts, answering to the turns of the axis through the regulator; and when the fly is put together, as in Fig. 1, the scale rests upon the regulator, and shews how far the regulator is moved either way in adjusting the fly. After having, by the assistance of the regulator, found the true position of the vanes, which would give the true distance sailed, I have sometimes made the fly a fixture throughout; but I prefer the adjustable fly.

"The register I use is constructed in manner following: that is to say: Fig. 2, in the aforesaid drawing, represents the register in one of its forms. It may be carried either in the vessel's cabin, or be suspended over the stern, by the ears *a* and *b*, in the same Fig. 2, so as to turn freely towards the fly at all times. Fig. 3, in the same drawing, represents the inside movement or train of wheels with its dial. This is fixed within the cylinder Fig. 2, and turns the index on its dial. The pinion *d*, in the same Fig. 3, has upon its inner end eight leaves, which moves the first or contrate wheel *b*, which has forty-eight teeth; and by its pinion of six leaves it moves the second wheel *c*, which has sixty teeth. This wheel *c*, by its pinion of six leaves, moves the third wheel *d*, of sixty teeth. This wheel *d*, by its pinion of six leaves, moves the fourth wheel *e* of sixty teeth; and this wheel *e*, by its pinion of six leaves, moves the fifth wheel *f*, of sixty teeth, which carries the index *g* on the end of its pinion. Its dial is graduated into one hundred divisions, each of which answers to one mile, and is numbered 10, 20, 30, 40, 50, 60, 70, 80, 90, 100; and, by the addition of more wheels, in like manner, the register will be capable of shewing any necessary distance whatever. An endless screw would produce the same effect in giving motion to the register as the pinion *d*, but I give the preference to the pinion. Fig. 4, in the said drawing, represents the register in another form. It has a similar train of wheels as the former, with the addition of one more wheel of sixty teeth, which extends the calculation of the distance the vessel sails to a thousand miles. The form of this register, by a circular disposition of the wheels, is round, and is enclosed in a round case, which is graduated for the purpose of shewing the ship's lee way, as will be shewn hereafter. This register has three dials on its face; one of which is graduated

graduated into ten parts, anſwering to tenths of miles, and is numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 10. The index on this dial moves round once every mile the veſſel ſails, each diviſion counting one-tenth of a mile. The large dial is ſimilar to the dial on Fig. 3, deſcribed above. The other of the laſt-mentioned three dials is alſo divided into ten parts, and is numbered 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000. The index on this dial moves round it once every one thouſand miles, each diviſion anſwering to one hundred miles. This regiſter has an arm or cramp *a*, fixed at one of its ends to the bottom of the box, by a ſcrew or otherwiſe, ſo as to admit of the regiſter's turning freely upon it: and by the other end of this arm or cramp the regiſter is ſecured to ſome convenient part of the veſſel. On one-half of the outſide of the circumference of the box is graduated thirty-two equal diviſions, correſponding with the diviſions of the compaſs, and an index, which is joined at one of its ends to the cramp, is brought to the edge of the box, and turned up, ſo as to anſwer the purpoſe of an index. When the veſſel makes lee-way, the fly commonly falls to windward, nearly in proportion to that lee-way, and by the fly being to windward, the pinion of the regiſter is turned the ſame way, and brings a correſponding figure or point which is marked on the box to the beforementioned index, and this denotes the number of points the veſſel makes to leeward.

" The form and portions of the regiſter may be ſo varied as to expreſs, in other denominations of ſea-meaſure, the diſtance ſailed, if found to be more convenient than the above. And the form, ſize, and proportions of the fly may be alſo varied ſo as to accommodate it to a regiſter of any calculation. So alſo may the ſhape of the vanes be varied, if their true poſition be ſtrictly attended to, for they are all capable of variation, from any given dimenſions, and the eſſential principles are ſtill retained.

" The pinions of the regiſter I generally make of bell-metal, and the other parts of the machine of braſs. Theſe materials I give the preference to; yet other materials will anſwer, provided they are of ſuch kind as will endure the effects of friction and of ſalt water. For the better illuſtration and deſcription of the fly which I uſe, and which I prefer, I have in the annexed drawings deſcribed one of four vanes, and its correſponding parts, ſhewing the proportions they bear to each other.

" Fig. 1, in the ſaid drawing, repreſents the centre piece or virtual axis. This is ſix inches and an half long, and about one-fifth of an inch in diameter. On one end is a ſcrew, about two inches long, and at the other is an eye hole, to faſten the line to, as in Fig. 1. And at the diſtance of about one inch and an half from the eye hole is a collet and pin, which ſecures the collar-piece to its place.

" The collar-piece is about three-fourths of an inch long, and half an inch thick at the largeſt end, having its ſides at right angles with each other, and terminating conically at its head end. It has a hole through its centre large enough to receive the centre piece or axis, to which it is ſcrewed by the collet and pin, ſo that it may turn freely on the axis.

" The regulator or adjuſtment is about one-fourth of an inch thick. Its largeſt ſurface is an inch and an eighth of an inch over, and being a little tapering, its ſmalleſt ſurface is left an inch over. It has a tapped hole through its centre, fitted to the ſcrew on the end of the axis, where it belongs.

" The four vanes are all of equal ſtrength, and about a ſixteenth part of an inch thick; they reſemble in form a right-angled triangle, whoſe baſe is eight inches, and whoſe perpendicular is three inches. A piece is cut off from the acute angle, which leaves the end about half an inch wide. A piece alſo muſt be cut out from the right angle, running nearly parallel with the baſe, ſufficient to prevent the vanes croſſing the centre, and thereby counteracting each other. The piece cut from the fly I am deſcribing is about one inch and three-fourths of an inch long, and half an inch wide; and muſt be varied according to the proportions of the fly. The vanes muſt be perfectly flat, and uniformly alike.

" I make a ſcale, on which are the Figs. 2, 4, 6: under which figures are twenty diviſions, anſwering each to one turn of the axis through the regulator or adjuſtment; and when the outer edge of the regulator or adjuſtment ſtands at the diviſion againſt Fig. 4, in the aforeſaid ſcale, the fly is ſuppoſed to be rightly regulated or adjuſted; but if, on trial, it is found otherwiſe, then, by turning the axis, the regulator or adjuſtment is moved, and the motion of the fly altered at pleaſure. Moving the regulator or adjuſtment towards Fig. 6, in the ſcale, increaſes the motion of the fly: and moving the regulator or adjuſtment towards Fig. 2, in the ſcale, diminiſhes the motion. Every turn of the axis, either way, alters the motion of the fly about three miles in an hundred. The opening in the vanes ſhould be of ſufficient length to give freedom to the ſcrews which bind the vanes to the regulator or adjuſtment when it is moved.

" The fly being thus completed, the vanes ſtand both in a conical and angular poſition, with regard to their centre or axis, and incline the fly to turn but one way; and as their angular poſition is increaſed or diminiſhed, ſo will be the number of revolutions of the fly in ſailing any given diſtance.

" For particular purpoſes the motion of the fly may be increaſed two, three, and even four times faſter than is uſual. This may be done either by enlarging the regulator or adjuſtment, or moving it farther towards the collar piece, ſo as to extend the broad ends of the vanes farther from the axis or centre, that is, farther aſunder; in which caſe the ſame regiſter will ſtill anſwer, if read accordingly. If the fly is conſtructed agreeably to the ſize and proportions here given, and is accurately regulated or adjuſted, ſo as to give the true diſtance ſailed, the broad ends of the oppoſite vanes will be an inch and three-eighths of an inch aſunder. And in caſe of any accident that the fly may meet with at ſea, or otherwiſe, the above diſtance, being examined by a pair of compaſſes, will be a direction to the mariner how to reſtore the fly to its former accuracy of meaſurement, the narrow ends of the vanes that are attached to the collar piece remaining fixed.

" The line, which I prefer to a chain, ſhould be made of good materials, be well twiſted, and about the ſize of a common log line. The line connects the fly and regiſter together. Its length ſhould be in proportion to the ſize of the veſſel, that the fly may be ſo far diſtant from the ſtern of the veſſel as not to be affected by the

the eddy of the veſſel's wake, which is often found to extend from fifteen to twenty-five fathoms aſtern. One end of the line is faſtened to the pinion of the regiſter, which, in Figs. 2 and 4, is marked *d*, and the other end is faſtened to the head end of the fly. See Fig. 1.

"The fly is towed perpetually after the veſſel at ſea, and its revolutions are communicated to the regiſter by the line, and theſe in exact proportion to the velocity of the veſſel through the water.

"There ſhould be no impediment or obſtruction about the line to prevent its turning freely, or about the regiſter to prevent it from turning the pinion to which the line is faſtened in a direction with the fly, eſpecially when the veſſel's lee-way is neceſſary to be known.

"The log, as now improved, and uſed, has the properties and advantages over my former log, hereinafter mentioned; that is to ſay:

"The fly of the improved log has an eaſy and efficacious mode or principle of regulation, by which its motion may be altered at pleaſure, and with great uniformity and preciſion. But my former log did not poſſeſs theſe advantages in ſo perfect a degree.

"The fly of the improved log, on which all accuracy of meaſurement depends, is, as beforementioned, compoſed of regular figures, ſuch as planes and ſquares, which admit of the greateſt uniformity and exactneſs in the workmanſhip of it; and its eſſential parts, and their true poſitions, admit of ſtrict examination by the application of inſtruments in common uſe, ſuch as the ſquare, compaſſes, and parallel-ruler: and, by the help of theſe, trifling errors may be diſcovered and corrected without the trouble of experiments by water. Theſe conveniencies my former log was quite deſtitute of. The improved log has a fly particularly adapted to very ſlow motion of the veſſel, when ſhe ſails leſs than two miles an hour, which is alſo to be uſed when the veſſel is lying to the wind in bad weather, and drifting, to give the diſtance ſhe drifts an hour, as is above deſcribed, and the ſame regiſter anſwers for this fly alſo. But my former log being heavier, was inclined to ſink in ſlow motion, and was alſo deficient in its power of action in ſlow ſailing, which could not be remedied without enlarging the machine too much for common uſe, or without increaſing the friction to a degree that would wear out the machine in a ſhort time. The improved log may have two or more flies with one regiſter, the fly being an inconſiderable part of the expenſe of the whole machine, in which caſe, if one fly is loſt, it may be eaſily replaced; but if an accident of this kind happened to my former log, the injury could not eaſily be repaired. This circumſtance renders the improved log much more convenient in practice, and its moſt expenſive part, namely the regiſter, leſs liable to be loſt, and leſs liable to accidents. It is alſo more durable, as the train of wheels or regiſter is kept clean and dry. It is alſo more certain in its performance, not being ſo liable as my former log to obſtructions at ſea, by ſea weeds, or other floating ſubſtances. The improved log is more portable and convenient for conveyance, its conſtruction is leſs expenſive, and it is more eaſily underſtood and repaired by common mechanicks.

"When there is no obſtruction between the fly and the box, it ſhews on the box of the regiſter the number of points lee-way the veſſel makes; but this valuable acquiſition could not be derived from my former log. The regiſter of the improved log is kept on-board the veſſel, in which the diſtance ſailed can at all times be ſeen. Whereas the whole of my former log went in the water, and the regiſter of it could not be ſeen without taking it into the veſſel."
